Number 1 on your Feedback card

From the Hamshack

Barry isbelle KC4IDE, Richmond VA Wayne, I think you are tops! I've been a Tech for a couple years—back after being dumped by ARRL's "Incentive Licensing." The team here in Richmond has graduated 60+ Novices in the last year! Most instructors are Techs. Keep pushing us to give back to the hobby that gives us joy.

John Devon KI6DQ Okay, I'll subscribe! *73* features superior writing and a forward-looking attitude, without forgetting radio's past. Why is there so much "history" between you and the ARRL? And how can ham radio compete against computers and BBSs?

The League? I've been on their case to be more responsive to us members for 40 years. . . and they've been hating me for speaking up for 40 years. . . Wayne

Steve Baumrucker WD4MKQ The Nov. Fire-Ball and QRP articles were both fun and exciting. It is sad that in this age of illogic a man with such reasonable views should be cast as "an unreasonable man" (by himself, no less). Your editorials are consistently stimulating. I give *73* credit for prompting me to start a ham radio club at the local middle school. It is a small contribution, but "the journey of 1000 miles begins with the first step."

Fine, Steve. Now how about some pictures of your club?. . . Wayne

Paul Adams WB5EVO Thanks for your inspiring editorials and a great ham magazine. I've been licensed since 1971, and you've talked me into trying just about every phase from CW to ATV, including RTTY, SSTV, 160m thru 1296 MHz. Next is packet.

It's about time, Paul. . . Wayne

Bill Weir KA7DTN, Flagstaff AZ I've enjoyed your "Never Say Die," construction articles, and columns since the mid '60s. So how come your predictions and opinions always seem right? Most educational! Keep up the great work, gang.

I thought I was wrong once, but I was mistaken. . . Wayne

Tom Maynard, Hinckley IL About 20 years ago as a Novice I remember being amazed by Wayne's audacious attitude toward the ARRL. Now, having achieved enough success, I'm getting back into the hobby and Wayne ain't changed a bit. After trying a few issues of the other ham magazines, it seems as if *73* is the only one worth buying. Thanks, Wayne, for hanging in there and making my return a welcome one.

So stop sniveling and get your ticket. . . Wayne

Jim Blizzard AB4YC, Alabaster AL Keep up the good work! I've been a ham since March 1990, and have been buying your magazine off the newsstand since February. It's fun to read your "Never Say Die" each month.

It's a shame, though, that you have to beg, plead, and scream at hams to get off their amplifiers and get busy sharing this exciting hobby with non-hams. There are so many dimensions to ham radio—something for *everyone*.

Fortunately for me, there is an active group of hams where I work (at the phone company) who are interested in teaching others about amateur radio. That's how I became involved last December.

This fall we're going to have classes for both non-hams and hams interested in upgrading. The class will include traffic handling, packet, RTTY, hands-on CW, QSO practice, DXing and hints, and theory.

Just wanted you to know there are some of us on the go.

Gutless Dweeb 1NERD At the ARRL Forum at Boxborough it was suggested that hams could pass along their used magazines to their local school libraries, hoping kids might get exposed to 'em. Tom (W1 director) said it would be better to just purchase new League materials and donate them. Someone suggested the League should have had a booth at the Eastern States Exposition (a humongous fair), since it is near HQ. Price said no, the hams in California might want them to do the same and they can't be everywhere. So we're nowhere. Instead of being considered, every suggestion was argued and defensively put down with lame rebuttals.

This reader is scared silly that the ARRL may find out who he is, so I've withheld his name. How does the League generate such utter terror?
. . . Wayne

Gene Griggs N3IEW, Milford DE I used your 20 wpm tape and passed the 13 wpm test. I have been preaching your code system. I hope your shake-up of the music business is progressing—it's sorely needed. I spent 3 years on the road as a professional saxophonist and found it's not how good you are, but who you know that gets you the breaks. Love the new look of *73* and read your editorials first. Take care and watch your stress level.

Give me three years to turn the music business around and make it safe for talented performers. . . for a change. . . Wayne

Mike & Linda Simmons WB9CWE/KA9LWE As "900" telephone numbers are getting more popular, we were wondering if *73* might set one up and charge around $5 for a trial subscription. This might attract young Novices.

We're doing this with CD Review, *allowing readers to hear samples of new CD releases and to get a short message from me on what I've been doing. It takes a lot of activity to make a 900 number pay off, and I doubt we could get enough ham calls. . . but we'll set it up and see how it goes as soon as we can.*
. . . Wayne

Ryan Lughermo, Midland MI Uncle Wayne, I need your help again. I acquired an Apple IIc computer, but the way the damned ham industry is, everything is for the IBM. I cannot find software for all aspects of radio. In these days of much-needed youth in the ham ranks, how does a college student paying his own way get into this hobby without paying an arm and a leg? You bet I'm not going to buy an IBM (I can't afford it, anyway!) just to get into ham radio.

People need to stop and think. It's not just the code that discourages youth. How about the cost of everything? I didn't come from a family that bought whatever I wanted. Please voice the opinion to manufacturers if you get the chance. Your voice is much more respected in the ham world than just a 20-year-old college student's. Anyway, if any of your readers has any software for the Apple IIc computer, I need their help.

Keep on writing those great editorials that actually make people think, as it's the part of each issue I read first, even before the table of contents!

My quick scan of CompuServe's HAMNET data libraries turned up a few Apple programs: two CW trainers, two MUF programs, an antenna design program, and a toroid transformer design program. I haven't tried CompuServe's Apple-specific forums, so I'm sure with a bit of digging you'll turn up more.

In general, IBM is where the bucks are, comercially, but it's never stopped people from writing their own software and sharing it with others via on-line information services and BBs. If you see a need, why not fill it?

Nuge's Fearless Prediction: You won't do it!

My experience at Portable 100 *and* PICO *magazines (primarily non-IBM) has been that, while hams are often the most vocal about* wanting *certain programs, they're the least likely to actually* do something *about writing them. If you'd care to prove me wrong, you'd be doing your fellow Apple-type hams quite a favor. . . Nuge WB8GLQ*

Look in "Barter 'n' Buy." There is usually at least one ad for ham Apple software. Then, there's "RTTY Loop." Dr. Leavey WA3AJR has mentioned Apple software in some of his columns. You can contact him by letter or e-mail.
. . . Linda KA1UKM

Mike KB2JNB I recently finished your latest copy of *73 Magazine* and I thought it was great. I was reading the story about kids in ham radio and how much they enjoy it. Being a young amateur myself, I enjoyed reading about kids my age. I'd like to hear more about this in the future.

R.R. De Jongh WB7CPT, Bellevue WA Just a few lines to thank you for *73*, the only real ham magazine left! With the demise of the other New Hampshire offering, and the subsequent substitution of something less than satisfactory, I find that I worry somewhat about *73*. I see a trend in *73* that makes me somewhat uneasy—the "QSTing" of *73*! That is, the increasing number of columns and nontech articles and the reduction of tech and construction articles. I'd hoped that with the lack of competition, you wouldn't have to resort to all that filler, being swamped with tech material. What happened?

I still enjoy your editorials and agree with about 75 percent of them. . . .

While we put as many construction articles in 73 as possible, not everyone likes to sit down at the workbench with a hot soldering iron! We like to round out each issue with stories about what people are actually doing with amateur radio. We have special interest columns since there are so many facets of the hobby, and I think you'll find that many of these columns have construction hints and projects in them, in addition to our regular articles. What one person considers filler is another's filling (I prefer strawberry)!
. . . Bill WB8ELK

Number 2 on your Feedback card

NEVER SAY DIE

Wayne Green W2NSD/1

Your IOU Is Due

Let's see a quick show of hands . . . how many of you have gotten some fun out of amateur radio. . . sometime? Now, one more try. . . anyone actually learn anything of value as a result of the hobby? Come on now, none of that furtive, shifty-eyed, sullen silence baloney, I want to see some hands.

Okay, maybe you haven't done all that much in amateur radio. . . 90% of us haven't. Maybe I haven't been able (yet) to con you into getting out of your rut and trying packet, RTTY, SSTV, ORP, OSCAR or any of the other fantastic things there are to do in amateur radio, but even if you've only taken advantage of 1% of the fantastic electronic feast you have available to you, you have a debt to the hobby and it's now time to call that debt. Your IOU is due.

Yes, I see some of you looking uneasily around, hoping maybe someone else will do what needs to be done. I know what you're saying. You're, sigh, too busy with other things. And after all, hamming is only a hobby. Besides, you're tired. Yes, I know, over half of all licensed amateurs aren't active. . . haven't been in years. . . so what's the big deal?

"All right, already," you're saying about now. Now what does Wayne want me to do? And why, pray tell, should I bother? The hobby has had its ups and downs, but it's still here 45 years after we got back on the air after WWII. So what's the big deal now?

Well, to be truthful, it may be nothing at all. . . just another false alarm. But our gas gauge looks like it's finally running on empty. Maybe it's just broken. Still, if you've been active for very long. . . I've been on the air for 52 years now. . . you know our bands are in the worst mess they've ever been in. And I'm sure you're aware that we haven't contributed much in the way of service or technology to pay for the rent on our bands in the last 25 years.

It takes youngsters to make a revolution. It's always the students who bring things to a head. Alas, we have almost no kids in amateur radio anymore, so all that's left is us old-timers. No wonder we haven't had a revolution yet.

A corporation which so mismanaged its assets as the League has ours would be facing takeover bids. . . or at least a stockholder revolt. If you're a member of the ARRL, you're a stockholder. Say, is Wayne "bashing" the League again? No, not yet, but I may. . . I may.

Three Main Problems

In case your memory is short, let's review what's broken and needs to be fixed. Yes, I know I've written about all this before. . . so what are they? (1) We need to clean up the messes we've allowed to build up on our bands. (2) We need to get serious about attracting young new hams. (3a) A WARC is coming next year in Madrid and we're woefully unprepared to do anything but spend a lot of money sending over League vacationers. (3b) Followed by a Geneva WARC in 1993, for which we're equally unprepared except for ARRL hotel reservations.

Those are the problems. Now, how about solutions? Obviously there isn't much you can do personally about these miseries. There isn't even much I can do as an individual. . . other than try to get as many amateurs as possible to understand what's going on and how to go about fixing things.

The fix is both easy and difficult. The easy part is your voting in new ARRL directors in the next election (they're re-elected every two years). The difficult part is trying to convince hard-core League members that there's anything wrong. Oh, they're aware of how bad our bands are, but they seem to expect the FCC to clean things up, not the League. Self policing? No, they don't think they recall anyone promising the FCC anything like that.

These old birds get upset when someone tries to tell them that the FCC views us as a royal pain. They vaguely recognize on some level that we're keeping commercial interests from using billions of dollars of desperately needed frequencies. But heck, we've always had 'em. They don't like to think about the commercial pressures to provide more radio services. They know that money talks, but haven't really figured out what this means at the ITU or with our government in Washington.

If you're an ARRL member but don't want to "get involved" you can just be sure to not vote for the incumbent director in the next election. If you're a member and feel you owe more to amateur radio than one vote you'll start looking for someone to get behind and run for director. They have to have been a continuous member for at least four years and not be involved with the ham industry. It'll be a plus if they have some business experience, something which is sadly lacking with far too many current directors.

If you're not a member you can try to get your ARRL friends and fellow club members to wake up and smell the mess.

Should you join the League and try to fight from within, as they so highly recommend? You have ten times the power to be heard *before* they get your money. Once they have it, you've lost your leverage. If they show some signs of actually accepting their responsibility to protect our hobby, then they're worth anything they have the guts to charge.

As a 50-year League member I really hate the way they've allowed our bands to deteriorate. For instance, they should have cleaned up the KV4FZ and K1MAN messes long ago. And what happened to their promise to bring in 50,000 new hams?

And how many Third World country leaders have ARRL representatives visited recently in preparation for WARC?

Your vote for a new director in your division will get the ball rolling. It'll let 'em know they have to do more than just spend your money. You demand some service for your dues. You owe amateur radio this for the benefits it's brought to you. . . and for those it's made available, even if you haven't enjoyed them.

What If I'm Wrong?

As the old saying goes, I thought I was wrong once, but I was wrong about that. Let's suppose, though, that this time I'm wrong. . . that our bands are peachy. . . a model of which we can be proud and not one that commercial interests can exploit. Let's suppose that we really aren't just a bunch of crotchety, quarrelsome old men, largely retired, enjoying a fun hobby in our old age, paid for by the general public and preventing them from getting communications services they'd pay billions to get. Let's suppose that we really do have thousands of kids getting licenses, even though we don't see them at hamfests or club meetings, or hear them on the air. . . and they haven't shown up on the FCC statistics.

Let's suppose that the Third World countries, the ones who have the most votes at the ITU, aren't mad at past visiting American and European hams who have flaunted their rules. Let's suppose they are aware of the enormous benefits amateur radio could bring to their country, even though no one has ever mentioned it to them. . . and that they will be happy to give up their claims for shortwave broadcasting frequencies and other radio needs. Let's forget that since their telephone systems are almost nonexistent most businesses have to use radio communications, for which frequencies are desperately needed. I've mentioned all these things many times before and most of you have forgotten them, so one more time should be easy.

Okay, then our hobby is hunky-dory and I'm a gloom and doom curmudgeon for even suggesting the ARRL has shirked its responsibility to manage things. Even so, what's the possible harm if you elect a new director? One maybe with some serious business and marketing experience? Heck, maybe even someone who hasn't been an ARRL official for the last twenty years. What will it hurt?

Now, if that's ARRL-bashing, please advise how you figure that. And have enough guts to sign your call.

Your Biggest Thrill

When I asked if you've ever had fun with amateur radio, what came to mind? Think back. What was your most exciting ham experience? I've asked many hams this and gotten some fascinating stories. Now I'm asking you, knowing the *73* readers will enjoy your experience as much as I.

How long should the story be? As long as it takes, but if you run off at the word processor our editors will cut you down to size. If you can send a floppy along with the hard copy, so much the better. Don't forget a picture of yourself too, just in case we think the readers will enjoy your story.

Most of my truly exciting times have been while on DXpeditions. I'll never forget a minute of any of 'em. On my first, to Navassa in 1958, it was one adventure after another. First it was weathering a hurricane at sea. . . then almost crashing on a coral reef. . . then almost getting shot by the Haitian police. . . then having to dive in shark-infested wa-

QRX . . .

EDITED BY LINDA RENEAU KA1UKM

Photo A. At the 1990 Space Symposium in Houston, Texas, the AMSAT Board of Directors presented Andy MacAllister WA5ZIB with an award for promoting amateur satellite operation through his "Hamsats" column in 73 Magazine. *See his report on the symposium in this issue!*

In February, Time's Up

Last summer the FCC requested 20-meter nets involved in frequency and operating disputes to come up with their own ideas to solve the problem. By late fall, five net managers had responded and others were asking for more time. The FCC set a deadline of February 1, 1991 for those nets to present their ideas and plans. The hope is that the amateurs involved will be able to solve their own problems, otherwise the FCC might be forced to act.

The ARRL states that the three main areas of dispute are resolvable by enforcement of existing FCC regulations. These areas include specific illegal activities: third-party traffic when there is no third-party agreement between countries; malicious interference; and one-way broadcasts which go beyond accepted norms for transmission on the amateur bands. If the amateurs cannot engage in reasonable discussions to solve these matters among themselves, the FCC may be forced to develop and enforce restrictive rules and regulations that would hurt the entire Amateur Radio Service. TNX *B-N-T Bulletin, Vol. 19, Issue 10.*

W1AW Packet BBS

The ARRL has reinstated its packet radio BBS, W1AW-4, after more than a year off the air. The system uses Kenwood radios, Kamtronics TNCs, MSYS multiconnect BBS software, and a Tandy 1000, donated by Tandy.

The system is currently on 145.01 MHz with a backbone for forwarding on 221.05 MHz. The system is primarily for dissemination of ARRL bulletins and will not exchange other bulletins (such as NEBBS or ALLBBS types). Users are requested not to make W1AW their "home" BBS. TNX *Zero Beat*, Nov. '90 issue.

Pays for Itself

MARS is saving soldiers and their families $5.2 million per year, and the Army $31.5 million, according to the U.S. Army Information Systems Command in Fort Huachuca, Arizona. Robert Sutton, Chief of the Army's Military Affiliate Radio System (MARS), says that these statistics, compiled before Desert Shield, could now be higher. Thirty-three Army MARS stations are operating in Saudi Arabia, making about 150–200 phone patches a day. "Army MARS operators have also processed over 4,200 MARS-grams," says Sutton. The MARS network consists of 233 military and 3,800 HF amateur radio stations.

The primary purpose of MARS, dating back to 1925, is to serve as an alternate means of communication during emergencies. For example, in recent years, MARS volunteers participated in emergency communications during both the San Francisco earthquake and Hurricane Hugo. During peaceful times, MARS contributes to the considerably important task of maintaining the morale and welfare of troops and their families. TNX Robert Sutton and Diana Hawkins.

Callsign Changes

It seems there is not a limit to the number of times a licensee can change callsigns, says Ray Adams N4BAQ of the Western Carolina ARS-VEC. A new callsign is available to any licensed amateur for the asking.

The FCC has always had a policy of issuing another callsign in exchange for any callsign the licensee considered obscene. Showing that a callsign is obscene, however, may depend on personal perception and interpretation. To avoid being accused of favoritism, the FCC changed the policy to cover the issuance of a new callsign to any licensed amateur who asked.

The licensee cannot choose what the new callsign will be, however; the block it's drawn from is determined by the class of license the applicant holds at the time of filing. TNX *The Magnolia Report, Vol. III, No. 10.*

Nomadness at WESCON/90

Technological wizard and writer Steve Roberts N4RVE, who has contributed many articles to *73 Magazine* in the past three years, appeared at WESCON/90 in the Anaheim Convention Center last November. Roberts has spent the last seven years combining eclectic technology and interests—ham gear, computers, solar power, bicycles, and a love of writing and traveling—into a working lifestyle of "nomadness." As a high-tech nomad, N4RVE has computed and hammed across America, first from his Winnebiko, and now from the Behemoth, his new recumbent bicycle.

After seven years, Nomadic Research Labs boasts well over 100 corporate sponsors, such as OrCAD, Hewlett-Packard, Apple Computer, and Sun Microsystems. From the Behemoth's computer systems, Roberts does bike-top publishing, word processing, satellite operation, sound editing, and graphics. TNX Kathryn Botsford of OrCAD.

A Ham At Last!

"I'm finally a licensed radio amateur, and one happy ham!" After 25 years in network television, well-known meteorologist Gordon Barnes is on the air. With the help and encouragement of many ham friends, Barnes began studying in the fall of 1989, and received his license in early 1990. His first contact was with Dave Jackson G0EGG in England.

Continued on page 8

Photo B. A MARS operator coordinates a radio net with affiliate MARS members.

QRX . . .

Continued from page 7

Gordon KC4OCA became interested in radio while growing up in Bermuda during World War II. A long-wire and Hallicrafter S-38 receiver kept him and his brother, Pete, informed on world events. Before long, they had raised an antenna farm among the cedars. Says Barnes, "The radio served as an educational device. This is how my brother and I learned about sports . . . they were broadcasting into countries where our men were fighting, and knowing that many foreigners would be listening for the first time, they took time and pride in explaining the game. . . . It was just great!"

Photo C. Gordon Barnes KC4OCA, a ham at last!

Barnes, who worked with CBS, WUSA-TV, and WFLA-TV, had his own syndicated weather network, and he also served as a weather consultant for many private and publicly-owned companies. A "weatherholic" whose predictive talents show the highest rates of accuracy, Barnes feels that nearly every service and product is affected by the weather. TNX Katherine S. Barnes.

A Tale of Two Stations

Stations WWV and WWVH are both operated by the National Institute of Standards and Technology. They both broadcast the time of day and standard time intervals, maritime storm information, omega reports, and geophysical alerts. Both broadcast AM (DSB) 10 kW on 2.5, 5, 10, and 15 MHz, with WWV also on 20 MHz. WWV is located at Fort Collins, Colorado, and WWVH is located in Kauai, Hawaii. All of WWV's antennas are omnidirectional half-wave dipoles, while WWVH has half-wave phased verticals with a cardioid pattern aimed at the west.

WWV's announcer is male and WWVH's announcer is female. On WWV, there's no tick on the 29th and 59th seconds; on WWVH, it's silent at seconds 00 and 30. Both stations broadcast a 440 Hz tone (the musical note "A" above "middle C"), for chart recorders and other automated devices, once each hour—on WWV, 3 minutes past the hour; on WWVH, 1 minute past the hour.

For propagation forecasts, hams can use the geo-alerts broadcast from WWV only at 18 minutes past each hour and updated every three hours at 0000, 0300, etc. These alerts contain information on the solar flux index measured daily at 1700 UTC in Ottawa, Canada; and the current K-index (distrubance of the earth's magnetic field) along with past and predicted 24-hour activity.

If you can't receive WWV on your rig, you can call (303) 499-7111 anytime and hear the same information. For more information on WWV and WWVH, write The National Institute of Standards and Technology, 2000 East County Road 58, Fort Collins CO 80542. TNX *Kettle Drums, Vol. XVI, Nos. 10 & 11.* Also, the Broward Amateur Radio Club Bulletin of October '90 (Pembroke Pines, Florida) has an excellent article, "WWV Solar Activity Reports," by Wally Orlidge W3PAE.

WARC Proposals

The FCC released its Second Notice of Inquiry concerning possible recommendations it might make at the 1992 World Administrative Radio Conference in February 1992. Before compiling this report, known as General Docket 89-554, the FCC considered comments on frequency spectrum needs from over 50 organizations, including the ARRL, NASA, Motorola, UPS, the Voice of America, and the National Association of Broadcasters. Three recommendations affect amateur radio frequencies that WARC has the power to reassign.

First, the FCC proposes that the amateur radio 40 meter band be shifted to 6900–7200 kHz (international broadcasters would get a separate 7200–7400 exclusive allocation, possibly to 7525 kHz). Second, the FCC proposes that Low Earth Oribiting Satellites (LEOs) use 930–931 MHz uplink and 420–421 MHz downlink. Third, the FCC recommends a satellite/digital sound service that would provide quality, wide-area service for mobile radio receivers; it is looking at 728–788 MHz, 1493–1525 MHz, and 2390–2450 MHz (in the amateur spectrum).

Further changes are probable before WARC '92. At WARC, each nation will have one vote. In the past, FCC recommendations have carried weight with WARC delegates. WARC agreements must be ratified by the U.S. Senate to become effective in the United States. TNX *Balanced Modulator.*

Satellite News

OSCAR-13 may only have two more years to orbit the earth . . . or, according to others, its orbit will correct itself due to factors not entirely known. Many believe AMSAT will come up with a replacement. The 1995 launch date for Phase III for a geosyncronous orbit hamsat, operable 24 hours a day, has been postponed indefinitely due to the high cost of such a mission. AMSAT has sent out a notice via ARRL requesting that, due to inadequate solar panel illumination, the OSCAR 10 transponder not be used until further notice. (Check, as this may have changed by the time this magazine is on the newsstands.)

Photo D. Guardian Angel Julio Rivera learns more about ham radio after delivering some last minute pointers to Joe Fairclough WB2JKJ, president of the Radio Club of JHS 22. Last Halloween, the "22 Crew" initiated "SAFE HOME" to escort club members and other youngsters to and from school. They are coordinating the operation on a Manhattan 220 MHz repeater. With Angels for advisers, the Crew will make it safe for hundreds of young people who want to be hams.

High Precision Frequency Standard

Use your TV set as a laboratory standard!

by Gardner Johnson

One of Murphy's laws of electronics is that "no other display looks as convincing as a digital display, no matter how wrong it is." Your handheld or laboratory counter or digitally-tuned communication equipment can easily become an example of this, unless it has been calibrated recently.

The problem is that the precision of such equipment can be no better than the precision of the internal time base. When the time-base frequency drifts, all of the indications or tuning frequencies drift in direct proportion. Almost all counter-type instruments use a quartz crystal-controlled oscillator as the time base, and unfortunately, they do drift with time as the crystal ages. Drift also results from changes in crystal and component temperatures, supply voltage variations, and the aging of other frequency-determining components.

The changes may not be significant for some equipment, such as a digitally-tuned AM radio, but a seven- or eight-digit counter or a VHF communications system is another story! An independent source of precisely known frequency is needed to verify the accuracy of, or to calibrate, the digital equipment. In many cases, the same is needed for analog equipment, such as in calibrating the sweep circuits of an oscilloscope. Better yet, this frequency source should be widely available and cheap.

TV Network Standards

Every color TV receiver tuned to a program originating at one of the four major U.S.A. networks has at least two such frequencies present internally. One of these is the color-burst frequency of 3.57954545454 MHz (3.58 MHz). The other is the horizontal sweep frequency of 15.7342657343 kHz (15.7 kHz). In the early days of color TV, they decided each network would phase-lock these two frequencies to use the 5 MHz output of a rubidium frequency standard at the network's master control station to ensure the desired accuracy of color reproduction. The rubidium standards have a rated maximum frequency drift of one part in 10 to the 11th power per month. In perspective, this is approximately 10,000 times better than the typical received accuracy of the WWV shortwave signals (the equivalent of one second in 31 centuries!)

The remarkable thing about the simple equipment shown in Photo A is that by taking advantage of the characteristics of phase-locked loops (PLLs), it creates a one-megahertz calibration signal having essentially the same long-term precision as the network rubidium standards. Adding decade dividers to the unit permits measurement of the frequency differences among the four major network rubidium standards! Since the standards are of unequal ages, they differ by several parts in ten to the 11th power. The only other equipment used to accomplish the measurements, besides an ordinary color TV receiver, was a very well-aged (1965) H-P 5248L electronic counter purchased complete with a time-interval plug-in for $37 at a ham swap-meet.

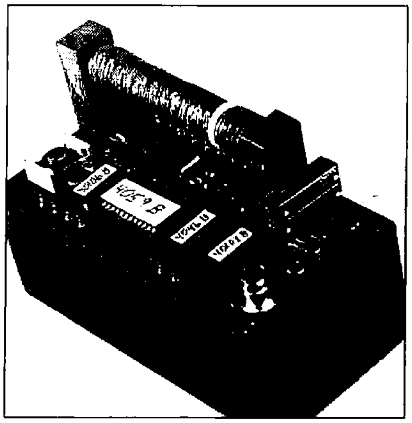

Photo A. The high-precision frequency standard in operation. (place the loopstick near the TVs horizontal output transformer)

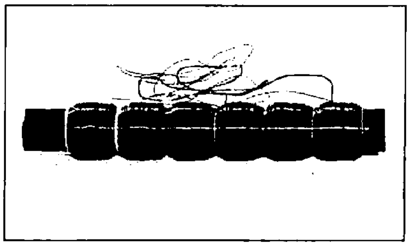

Photo B. The ferrite loopstick antenna is designed for maximum pickup of the TV set's 15.7 kHz horizontal sweep frequency.

Programs from ABC, CBS, and NBC are frequently interrupted by locally originated commercials which do not have rubidium frequency standard precision. It's unfortunately necessary to keep one eye (or ear) attentive to their program material so that the interruptions can be excluded from any measurement periods. PTL transmissions are rarely interrupted and maintain a frequency near the mean of the other networks.

Just a PLL

The circuit I'm going to describe is a simple PLL. It picks up a sample of the horizontal sweep signal of a color TV receiver that's tuned to a network program, then phase-locks a voltage-controlled oscillator (VCO) to the sample, using the frequency ratio 4004 to 63. This yields the desired, very precise one-megahertz output frequency.

Figure 1 is a block diagram and Figure 2 is the schematic for the simplified frequency standard. The 15.7 kHz pickup coil is a ferrite loopstick antenna tuned to the horizontal sweep frequency of an operating TV receiver. By picking this signal up magnetically from outside the TV set's cabinet, direct connection to the wiring inside the cabinet is avoided. This is a major safety consideration, as it rules out use of the much weaker 3.58 MHz signal. Many TV receivers have the chassis connected to one side of the power line—you guess which side! The resonant loopstick circuit has a Q of over 400, so it also acts as a very effective filter for the undesired signals prominent in or near an operating TV receiver.

The 15.7 kHz signal picked up by the loopstick is an excellent sine wave for eliminating other frequencies, but it's not ideal for operating the digital circuits which follow. The Schmitt buffers square up this sine wave without appreciably loading the tuned circuit, and they drive the CMOS 40103 divide-by-63 stage which follows.

The 40103 divider has eight flip-flops which can be arranged to divide an incoming pulse train by any number from 2 to 255. As used here, it divides the 15.7 kHz square wave signal from the Schmitt buffers by 63 to provide the 249.750249750 Hz (250 Hz) "reference signal" to pin 14 of the 4046 phase detector which follows. 250 Hz was chosen as the reference signal because it's the greatest common divisor of both the high precision 15.7 kHz signal from the loopstick

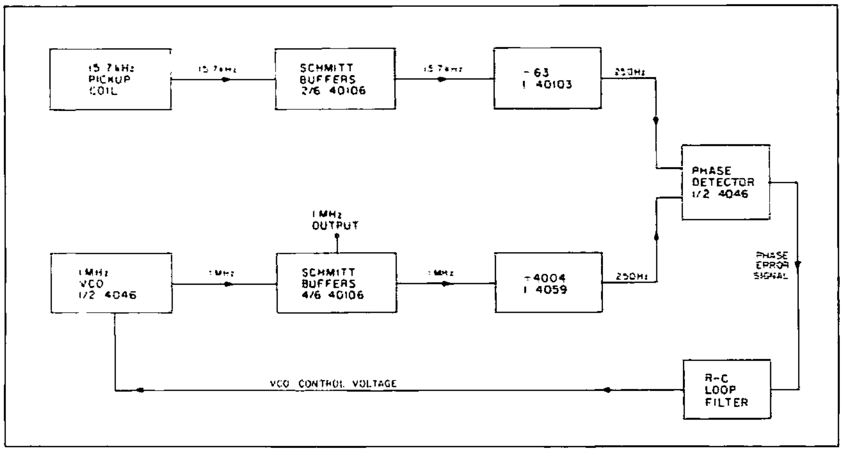

Figure 1. Block diagram of the frequency standard setup.

and the one-megahertz VCO signal that provides the unit's output.

The one-megahertz VCO is one of a number of separate functions physically located on the 4046 phase detector chip. The 4046 VCO is a well-engineered square-wave RC oscillator with useful harmonics up through the shortwave bands. You can make it oscillate at any frequency from less than one hertz to over two megahertz by choosing the proper external capacitor, two resistors, and a control voltage.

The capacitor, C6, and one resistor, R5, determine the frequency of oscillation when the control voltage equals the supply voltage. Resistors R7 plus R8 determine the frequency of oscillation when the control voltage is zero. By varying the control voltage between zero and the supply voltage, you can vary the oscillation frequency linearly, from the lower to the higher of these two frequencies.

For the present application, the capacitor and the three resistors have been chosen to yield an oscillation frequency of one megahertz when the control voltage is equal to half the supply voltage. Any deviation from the desired one megahertz is then corrected by a corresponding change in the control voltage.

The one-megahertz output of the VCO is passed through two Schmitt buffers for isolation, then fed into a 4059 divider. The versatile 4059 IC can be connected to divide an incoming pulse train by any number from 3 to 21,327. Used here, it divides the one-megahertz input from the buffers by 4004 to provide the 250 hertz "signal input" to pin 3 of the phase detector. If the VCO frequency shifts ever so slightly up or down from one megahertz, the 250 hertz signal frequency will increase or decrease in proportion.

Phase detector 2 of the 4046 compares the arrival times of the leading edges of the two 250 hertz signals, and outputs a signal that, after filtering, varies with the fraction of a cycle by which the two leading edges do not coincide. When the edges match perfectly, the filtered DC output is equal to half the supply voltage. If the one-megahertz oscillator drifts lower in frequency, the pulses from the 4059 divider will begin to arrive later, and the filtered DC output of the detector will increase, again in proportion. By applying the filtered output of the phase detector to the control voltage terminal of the VCO, the frequency of the VCO can thus be locked to the frequency of the TV receiver horizontal sweep. Although this part of the operation is analog in nature, it is enclosed within the overall digital loop, which maintains the necessary system long-term precision.

The RC filter performs two important functions. First, it filters out the 250 hertz (and any other) noise present on the output of the phase detector. If this noise reaches the VCO, it would frequency-modulate the VCO output, thereby degrading the short-term accuracy of the output signal. The long-term accuracy, however, would not be affected.

Secondly, the circuit includes a feedback loop around the VCO. This loop requires the usual amplitide and phase stabilization if it is to lock up very rapidly with no tendency to overshoot or oscillate. The simple 4-element filter used here does both jobs well, and a nearby "Hi-Fi" broadcast band receiver can detect no modulation on or near the one-megahertz output signal.

Building the Circuit

The prototype was built on a leftover scrap of pad-per-hole circuit board, but ordinary perfboard works just as well. I cut the board to form a new cover for a 3" x 6" plastic project box that encloses the wire-wrap connections, and I used turret lugs for mounting the few small parts on the top of the board. The lugs were staked in place, but press-in plastic based terminals are a good alternative.

Parts layout is not at all critical, except that the grounded end of the loopstick should be located near the end of the unit so that you can put it against the back of a TV set, if necessary, for maximum pickup. The loopstick should also be located at least an inch away from other metallic objects, as they may degrade its Q. The loopstick in Photo B is supported by inserting the ends in holes drilled halfway through two phenolic blocks. *[Ed. Note: An etched and drilled PC board is available which should help ease the construction process (see parts list).*

If you decide not to use the PC board layout, you can wire-wrap everything onto perfboard. Wiring is noncritical, except that the RC filter leads should be connected directly to the 4046 socket pins in order to keep the VCO control signal as clean as possible. Wiring was fast and easy, using 30 gauge insulated wire-wrap wire and an inexpensive hand-wrapping wand. One ancient truth was relearned the hard way, however: Never, never, never buy wire-wrap sockets with short two-wrap pins, no matter how high the quality or low the price!

The equipment only requires about 12 mil-

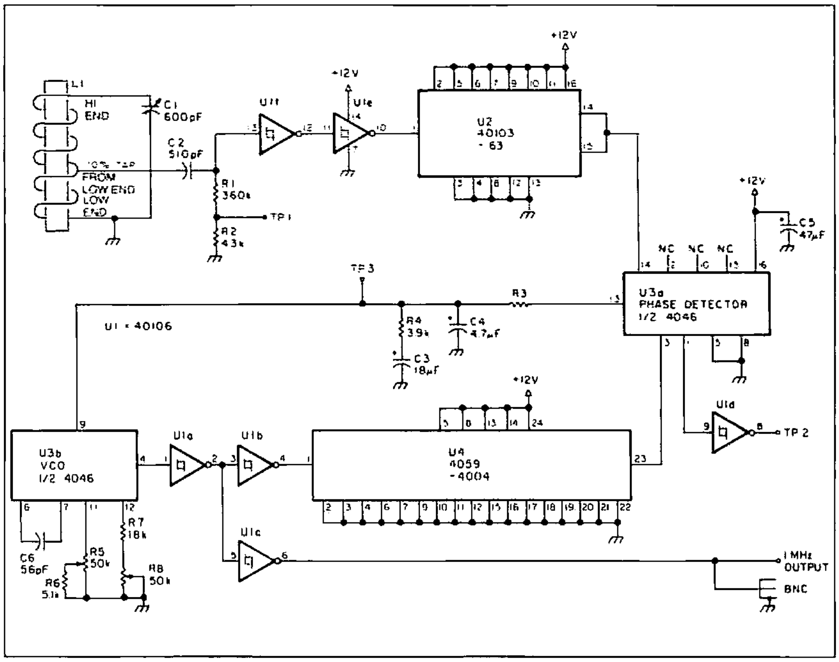

Figure 2. Schematic for the frequency standard.

liamperes (mA) of well-filtered, regulated 12-volt DC power. A 1.2 ampere wall-plug computer surplus power supply (used for the prototype) is 100 times larger than you need. You can easily assemble a small supply, using the many plans in back issues of *73 Magazine* if surplus is not available in your area. The supply voltage doesn't have to be exactly 12 volts DC; you can use your shack's 13.8 volt DC power supply as well.

Checkout

Recheck your wiring carefully, then apply the 12-volt DC power. If there's no smoke, and power appears only on the correct socket contacts, turn the power off. With the power off, insert the four ICs. To prevent ESD damage, keep one fingertip on the ground terminal while handling the ICs.

Set the two trim resistors at mid-scale and reapply the power. Next, place the unit close to the back of an operating color TV receiver and connect a 50 microampere (μA) DC meter from TP-1 to ground. (Almost any multimeter will serve if set on its lowest voltage or current range.) Adjust the trimmer capacitor for the peak meter indication. The peak will be very sharp due to the high loopstick Q.

Explore the vicinity of the back and sides of the TV receiver with the unit to locate the spot providing maximum pickup. Next, disconnect the sensitive meter and connect a 0–15 volt meter from TP-2 to ground. If the loopstick is picking up enough signal to operate the phase detector, the voltage at TP-2 will be about 0.2 volts.

Excessive loopstick signal could overload the buffer, so slowly move the unit away until the TP-2 voltage jumps to 11.8, which indicates insufficient signal. Move the unit about an inch closer to the point of maximum pickup, and leave it there. You can simplify this part of the checkout procedure if you have an oscilloscope. Connect the scope from the tap on the loopstick to ground, adjust the capacitor for maximum signal, and position the unit for 12 volts peak-to-peak. This gives the design center condition (when using a 12 volt supply), but the unit will operate satisfactorily over a wide range of loop signal strengths as long as the TP-2 voltage remains below half a volt.

The unit should be providing a very good

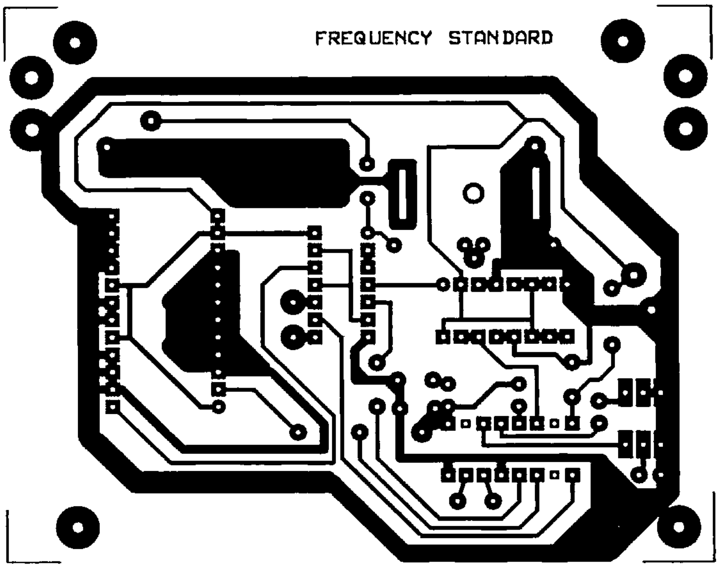

Figure 3. PC board foil pattern.

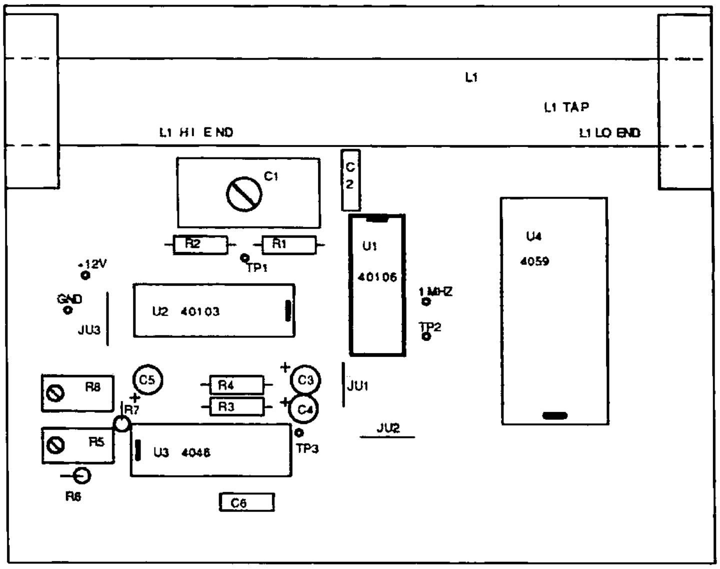

Figure 4. Parts Placement.

one-megahertz output signal at this point, but the trimming resistor adjustments should still be optimized for the particular 4046 in use, since the VCO sections vary a great deal from one 4046 brand to another. To do this, connect TP-3 to +12 volts with a clip lead and adjust R5 for an output frequency of roughly 1300 kHz. Next, connect TP-3 to ground and adjust R8 for an output frequency of roughly 700 kHz. Refine these initial settings until the two frequencies are equally spaced above and below one megahertz. If a counter is not available, you can measure these frequencies by tuning them in on a broadcast band receiver.

Remove the clip-lead and listen to the one-megahertz signal on the broadcast band receiver. If there is hum modulation, the most probable cause is hum on the output of the power supply. If there is 250 hertz modulation, the loop filter is at fault, possibly due to dried-out or leaky capacitors or ground loops in the filter wiring. A spectrum analyzer is even better than a broadcast band receiver for troubleshooting, but if you have a spectrum analyzer, you undoubtedly need no further suggestions!

The VCO frequency-control voltage at TP-3 is between 2 and 10 volts during normal circuit operation. If the TP-3 voltage drops to a few tenths of a volt, it indicates that the phase-locked loop is not locked. In that case, the uncontrolled output frequency will drop to around 700 kHz. It's good to give the TP-3 voltage a quick check a minute or two before making an important measurement. TP-3 is a very high-impedance point, and leaking loop filter capacitors, or connecting an ordinary multimeter, will result in 250 hertz modulation of the one-megahertz output.

Loopstick Details

The later version of the loopstick antenna as shown in Photo B has lower distributed capacitance and higher Q than the earlier versions. It's wound on an Amidon R33-050-400 ferrite rod core, with ¼" clear at each end for mounting. The remaining 3½" are covered with a single layer of tape to reduce the distributed capacitance between the windings and the fairly conductive core. Since Litz offers no advantages in this application, the wire used was number 30 nylon enamel.

The winding was subdivided into six 300-turn, layer-wound sections in order to reduce the end-to-end distributed capacitance while keeping the turns close to the core. The tap is located 180 turns from the start of the first coil. The measured inductance was 203 millihenries (mH) with a Q of 32 at 1000 hertz and a DC resistance of 35.5 ohms at 25°C.

These values permit the coil to resonate with the largest generally available adjustable trimmer capacitor without need for additional paralleled fixed capacitors. These values also permit taking the output to the buffer from only 10% of the total turns, which reduces the effect of buffer loading on the circuit Q by a factor of 100. Caution! R33 cores are fairly brittle. The completed loopstick is also commercially available if winding 1800 turns of wire is not for you (see the parts list).

Parts List

Capacitors

C1	700 pF compression mica trimmer (Circuit Specialists# 4215)
C2	510 pF to 1,000 pF, glass or mica
C3	18 µF, 50V tantalum such as M39003-01/2379*
C4	4.7 µF, 50V tantalum such as M39003-01/2368*
C5	47 µF, 20V tantalum M39003-01/2295
C6	56 pF to 68 pF glass or silver-mica

*20V parts would be satisfactory if of the correct capacitance.

Inductors

L1	200 mH (minimum) ferrite loopstick (see source #7)

Resistors

R1	360k ohms
R2	43k ohms
R3	5.1k ohms
R4	3.9k ohms
R5,R8	50k-ohm/25 turn adjustable trimmer (Circuit Specialists part# 950W50K, Mouser part# 594-64W503 or Digikey part# CEG54)
R6	5.1k ohms
R7	18k ohms

Semiconductors

U1	CD40106B CMOS hex Schmitt trigger
U2	CD40103B CMOS 8-stage presettable synchronous down counter
U3	CD4046B CMOS micropower phase-locked loop
U4	CD4059B CMOS programmable divide by N counter

Note: The "A" versions of all four ICs can be used, but they are more susceptible to ESD damage.

An etched and drilled PC board is available for $6 + $1.50 postage/handling from FAR Circuits, 18N640 Field Court, Dundee, IL 60118.

PLL Possibilities

The capabilities of the PLL create at least two opportunities. The first is for entrepreneurs to market completed units or kits. The second is for the ex-NBS NIST and the FCC to jointly persuade or require all TV networks to upgrade their color-burst frequencies to cesium beam precision.

Regarding the first, here are some possible design variations:

1. Add a divider chain to make numerous lower output frequencies available. Use synchronous dividers to minimize phase noise. Extend the chain to 0.001 or 0.0001 hertz. Add an FET buffer, a meter, and a switch for monitoring TP-1 and TP-3, and an LED indicator for TP-2.

2. Use a quartz crystal VCO (VCXO) in place of the 4046 RC VCO, again to minimize phase noise. Use a 10 or 100 MHz crystal to facilitate calibration of counters having short sampling periods. Use 74AC or 74F dividers to follow a 100 MHz VCXO. Use a 25 MHz fundamental VCXO and two doublers if the 100 MHz fifth-overtone VCXOs give cost or reliability problems.

3. Start with a TV tuner and IF appendages. The 3.58 MHz color-burst signal can then be phase-locked to a one-megahertz VCO by using 88 and 351 dividers. The lock frequency then becomes 11.3636363636 kHz, which improves PLL dynamic performance and permits still better filtering of the phase detector output. Add decade dividers for the higher VCO frequencies.

Regarding the second opportunity: A dozen dividers added to the unit would provide the long-term precision available to every standards laboratory, research group, business, and individual user in the world for under $100 plus a color TV receiver. Cesium beam standards have a rated precision of one part in 10 to the 12th power, the equivalent of one second in 31,000 years, the world standards of time and frequency. Unlike rubidium secondary standards, they're believed to be free from aging effects.

At the network master stations, the rubidium standards could be replaced with cesium beam standards for about $33,500 each, small change in that world. But there are even less expensive approaches. NIST already maintains a bank of cesium beam standards to control the transmission of WWV. The 60 kHz WWV signal is not subject to the Doppler shift problems of shortwave signals; suitable receiver systems have been available for about $1,800. By phase-locking the rubidium standards to the 60 kHz WWV signal, ten times higher precision can be obtained. A third possibility would be for NIST to supply a pilot frequency for phase-locking via phone lines. A fourth, would be to do the same thing via satellite, and a fifth would be for NIST or another agency to supply the cesium standards to the networks as a service to government agencies, businesses, and even the taxpayers.

The Final Unit

The unit in Photo A was later modified by the addition of a chain of decimal dividers to enable measurement of the difference of the network standards (requires counting 100,000,000,000 pulses). The well-aged H-P 5248L was used in the time-interval mode, counting its own internal 100 MHz clock pulses for a time determined by the 0.001 Hz (or 0.0005 Hz) pulses from the dividers. This circumvents the counter limitation of a 10-second maximum count interval for direct frequency measurement. In the 1000-second interval, it therefore counted 10^{11} pulses. The display shows only the last eight digits of the count, but they are the ones of interest. The time interval plug-in had slightly different delays in the start and stop channels, but they were calibrated out by use of measurements taken at a series of shorter times.

The procedure was to take repeated counts on each of the four network stations in sequence. The differences in the averages for each station thus corresponded to the differences in the frequencies of their rubidium standards. Similarly, any drift in the average of each group of four readings would correspond to the aging rate of the H-P 5248L clock oscillator, although no statistically significant difference was found.

The most impressive thing about the whole effort was the way the data repeated time after time. The total number of PLLs in the overall system, from those in the rubidium standards to those in the measuring system, must have been quite large. The signals from three of the four networks had to travel either 3,000 miles over land, or to a satellite and back, for good measure. The amount of short-term phase modulation of the VCXO must also have been very small, because the overall standard deviation of the 100 trillion count samples averaged about three counts! 73

MFJ SWR Analyzers

The MFJ-207 HF and 208 VHF portables.

MFJ Enterprises, Inc.
Box 494
Mississippi State MS 39762
Tel. (800) 647-1800; (601) 323-5869
TELEX: 53 4590 MFJSTKV
Price Class: MFJ-207, $100
MFJ-208, $ 90

Have you ever put up a dipole that was pre-cut to an exact length tor a specific frequency? Did it work as planned? Or, as in most cases, did you have to make so many trips between the shack and the antenna to check the SWR that you wore a path across the lawn?

Suppose you had a portable device you could take out to the antenna and make SWR tests on the spot? Think your life would be a little simpler?

Well, the folks at MFJ Enterprises—the manufacturer of all those neat make-it-easier-on-the-ham gadgets—have come up with two great boxes for testing antenna SWR. One, the Model 207, is for the HF spectrum of 1.75–30 MHz, and the other, the Model 208, is for the 142–156 MHz VHF user.

Both SWR analyzers are the same size and weight: 7.5 x 2.4 x 2.7 (HWD) inches and less than a pound. Both have an ON/OFF switch, frequency control, an SWR meter, and an SO-239 connector. They operate on a 9-volt battery or an optional (Model 1312) AC adapter. The latter might be fine for use in the shack, but I like the portability of battery operation.

A Test Run

Here at the new QTH of Radio WA4BLC, the antenna system has been slowly growing. Knowing that my wire antennas and VHF vertical are correctly set up (done the old hard way: In the shack—check the SWR, then back out and trim some more on the antenna, and back again), I decided to check the new SWR analyzers.

Using a short piece of RG-8X as a patch line, I connected the MFJ-207 (the HF version) directly to the Double Edged Sword's feedline, selected band B (includes 75–80 meters) and turned the unit's frequency control to find the lowest SWR reading. (The Double Edged Sword Antenna is a dipole system with legs cut for 40 and 75 meters, fed with one feedline.)

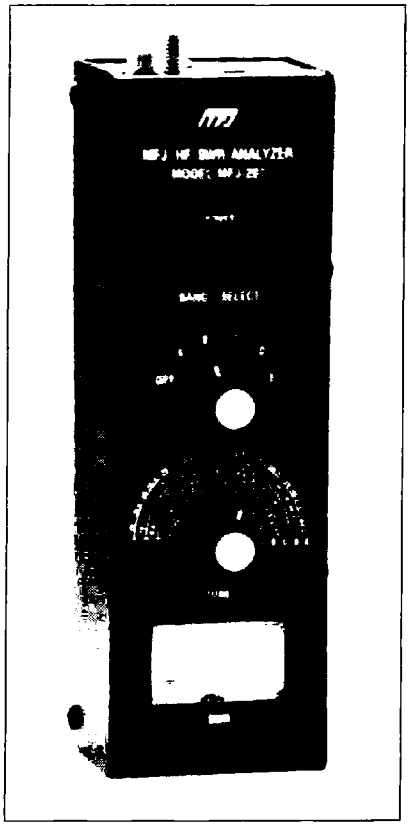
Once this reading was made, I tuned the receiver until I heard the 207's signal. The receiver accurately indicated the analyzer's frequency of lowest SWR. I repeated the process on 40 meters. The lowest SWR readings were exactly where they had been set last week.

This was an exercise in rechecking what I had already done (a known product) against the SWR analyzer (an unknown product). As both methods produced similar results, I am satisfied the Model 207 performs as designed.

Out of curiosity, I then connected the device to my Carolina Windom's feedline and tuned to see what would happen. Low SWR was indicated at many points over the HF spectrum. Some were inside the ham bands, others were not. All points were close enough to our bands to allow easy operation with a tuner.

Practical Operation

The test runs were done by tuning the 207's vernier dial, observing the built-in SWR meter, then pinpointing the 207's exact frequency on a receiver. The reason you must check the frequency with a receiver is that the vernier dial on the SWR analyzer is small and covers too broad a tuning range to be really accurate.



MFJ's SWR analyzers make proper antenna installation faster and easier.

Having seen the problem with the vernier readout, MFJ installed an RCA jack labeled RF OUT on the 207 (and 208) to allow direct connection with a frequency counter for a very accurate readout. This is great in the field, where no receiver is readily available.

Finding the SWR

The test run demonstrated how you would find the lowest SWR point for an antenna; however, the 207 can also be used to find an antenna's SWR at a pre-determined frequency. Connect the unit to the antenna being tested, set the vernier dial to the frequency desired (checking with a receiver or counter), and read the SWR.

If you have ever installed a multiband antenna, whether a 5-band vertical or a triband yagi beam, you know how very frustrating it is to keep running SWR checks from the shack. With the 207, you can tell directly from the antenna site (ground level for the vertical or on the tower for the beam) what the SWR will be at what frequencies. Then you can easily make adjustments before you tighten everything up.

Like the idea of tuning up your antenna matching device while not actually being on the air? The 207 can be set to your operating frequency and its signal injected into your tuner. Then you can adjust the tuner until the 207 displays a perfect 1:1 match.

The 207 worked great on my mobile antenna system, which consists of several Hustler resonators (coils) for the 75 and 40 meter bands. I had forgotten which coils were for what frequencies. Using the 207 I was able to quickiy identify the lowest SWR points (therefore the operational frequency) of each coil. It is also great for readjusting these ultra-sensitive antenna tips for new frequencies.

VHF Version

The Model MFJ-208 does for 2 meters what the 207 does for the HF band. It is identical in size, although somewhat simpler to operate as there is only one band to be concerned with

on the vernier dial. Tuning indication is more accurate.

It worked splendidly for retouching my 2 meter whips and rechecking my V-2 vertical. Good thing the V-2 checked out OK, as it was already up in the air.

Just for the fun of it, I checked a couple of those famous rubber-covered dummy loads we all use on our HTs. I figured the readings would be similar to real-life HT operation, as the 208 is about the same physical size as an HT (ground plane?). The best SWR a famous gain-style rubber-covered antenna showed was 2.25, and that was at 147 MHz. A very short type showed an SWR of 1.3, but that was above the band by a couple of MHz. A factory variety was on the money for frequency at 146 MHz, but the SWR was 2.3.

These results came as no great surprise and only go to prove a point: I don't think any of the short HT-type antennas do as well as they should be doing. In past lab tests, using very sophisticated equipment, I had reached the same conclusions.

Mobile VHF antennas can get pulled out at the car wash, but the Model 208 will get you back on target quickly.

Likes

Portability. You can use it in the field, your car, or up on a tower.

Readability. The SWR meter is easily read.

Controls. All the controls operate easily.

Cost. The cost is reasonable, even in today's dollars.

Possible Improvements

The vernier dial on the 207 is not very accurate, but use with a counter makes the dial redundant. Additionally, the dial can be moved on its shaft for calibration purposes (which I did). The 208's dial is quite accurate, possibly due to its limited frequency coverage.

The instructions are adequate for operation, but they should have included information about the methods of charting antenna SWR by frequency, and instruction on how to use that information for making antenna adjustments.

Recommendations

Would I recommend the MFJ Antenna analyzers to my fellow hams? Yes, and it is too bad I didn't have them a few weeks ago when I was setting up my antenna system. They could have prevented the new path worn in the grass from the antenna field to my shack's door.

One last comment: These SWR analyzers provide a means of accurately tuning antennas WITHOUT transmitting any signals. In other words, they reduce air pollution, as well as making the hams's life a little easier. 73

Bill Clarke WA4BLC, who has reviewed a lot of equipment for 73 readers over the past years, has a new address. You can now reach him at RD#2 Box 455-A, Altamont NY 12009. Says Bill, "I enjoy reviewing equipment I can get excited about."

TE SYSTEMS new **HPA Series** of high power amplifiers now available through select national distributors.

All amplifiers are linear (all-mode), automatic T/R switching, and incorporate optional GaAs FET preamp. Amps are usable with a wide input drive level range. Thermal shutdown protection and remote control capability included. All units are designed to ICAS ratings and meet FCC part 97 regulations. Approx. size is 2.8 × 10 × 11.5" and weight is 8 lbs.

Consult your local dealer or send directly for further product information.

Models also available without GaAs FET preamp (delete G suffix on model #). All units cover full amateur band – specify 10 MHz bandwidth for 420-450 MHz amplifier. Continuous duty repeater amps also available.

Amplifier capabilities: 100-200 MHz, 225-400 MHz, 1-2 GHz, Military (28V), Commercial, etc. also available – consult factory.

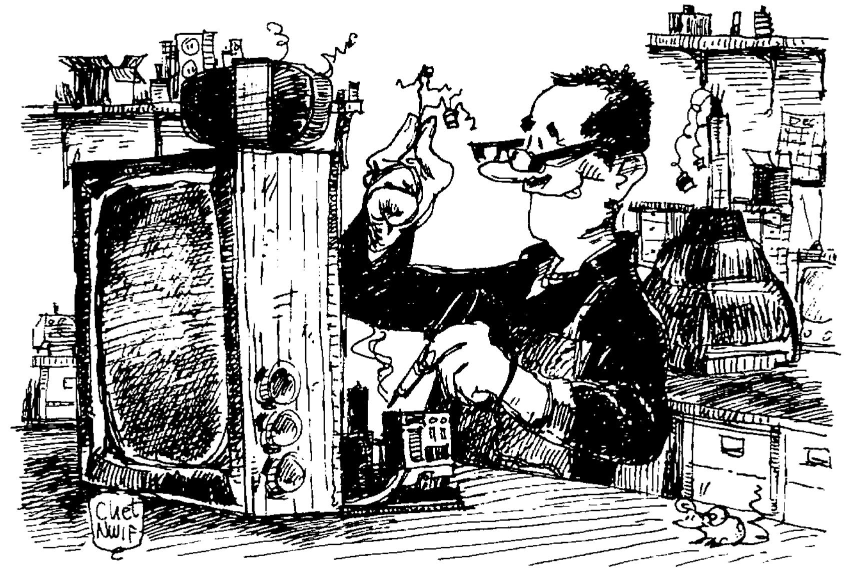
Scrounger's Guide to Recycled Electronics

Discover a goldmine of inexpensive parts.

by Jack Najork W5FG



Aside from Radio Shack, there are few commercial sources of electronic parts available to the builder or experimenter. Most catalog houses require minimum orders of $20 to $25, which is pretty discouraging to someone who needs just a few odds and ends for a weekend project.

However, if you are willing to do a bit of scrounging and desoldering, you can find an ample supply of parts just about anywhere. We live in a world conditioned to quickly discard anything electronic that is obsolete or doesn't work properly. The trash yards and dumps of America are filled with junked electronic products. The trick is to intercept them before they are carted off. A few words to friends and neighbors will insure that these jewels are held for your pickup. Aside from these "freebies," many items can be picked up at garage sales for a dollar or two. TV sets, radios, hi-fi combinations, CB radios, wireless telephones and car radios all contain parts that can be recycled for ham use. Let me give you some examples of components I've salvaged, modified (if necessary) and used for various projects. Then we'll get to the details of digging them out and identifying them.

From TV sets: ferrite cores and forms for RFI line filters and antenna baluns, slug-tuned RF coils, RF toroids, power supply rectifier diodes, filter caps, potentiometers, resistors, ceramic capacitors, switches, loudspeakers and many useless tubes. Some of the older or larger sets may include a power transformer.

From radios, wireless telephones and hi-fi combinations: ferrite rods, tuning capacitors, more slug-tuned coils and IF transformers, transistors, diodes, small loudspeakers, NiCd batteries and condenser microphones.

My home-brew transceiver sports an RF tuner (modified) that came from an old car radio. Double-balanced mixer and modulator transformers are wound on small ferrite slugs taken from low frequency IF transformers. The diodes came from a wireless telephone, as did most of the transistors used in the audio and IF stages. Some RF coils are wound on toroids made from slices of powdered-iron slugs—more on this later. The RF driver transistor in the transmitter section came from a CB radio, as did the "S" meter, loudspeaker and part of the metal housing. Truly, my junque box floweth over—and yours can also.

TV Sets

Warning: THE PICTURE TUBE OF ANY TV SET IS EXTREMELY HAZARDOUS, regardless of size. If mishandled, the tube can implode, flinging razor-like glass fragments with the force of a small bomb. UNDER NO CIRCUMSTANCES SHOULD YOU EVER STRIKE THE FACE OR BELL OF A PICTURE TUBE. Breaking a tube this way will produce a bomb-like implosion.

RF Coils, Toroids and Such

Unless your set is over 25 or 30 years old, the video IF section will contain 45 MHz slug-tuned coils and the audio section IF 4.5 MHz coils. (The audio coils are identifiable because they have many more turns.) The video coils can be stripped of their windings and used for RF circuits from 1.5 to 50 MHz. Most coils use ¼" diameter slugs which have a hollow hex core for insertion of a tuning tool. You can slice off small segments of these slugs, ⅛" or so thick, and use them as RF toroids. The easiest way to do this is to roll the slug back and forth under a single-edge razor blade or sharp knife. The powdered iron is quite soft and sections readily. Sand smooth the rough edges. Figure 1 shows the approximate inductance vs. turns for sections ⅛" thick. Thicker segments will yield slightly higher inductance, and vice versa. The Q factor of these coils is quite acceptable for most RF work, and I use them for oscillators and front-end receiver-tuned circuits.

Pocket radios, hi-fi sets, cordless telephones and CB radios contain many small, shielded RF and IF coils and transformers. Most sets use the standard 10.7 MHz and 455 kHz frequencies for FM and AM IF circuits, along with 25 MHz and 49 MHz for CB sets and cordless phones. A physical inspection will show the approximate resonant frequency of these devices, i.e. the 455 kHz transformers have many turns wound on small powdered iron bobbins while RF coils are wound on segmented plastic forms. Many of these devices will contain an inner powdered iron cup which fits over the coil form. The cups used for 10.7 MHz transformers and RF coils can also be used as toroid forms.

Figure 1 shows turns vs. inductance for RF cups 10/32" in diameter and 7/32" tall. The data in this figure should be taken as a general guide only. Manufacturers, variations in

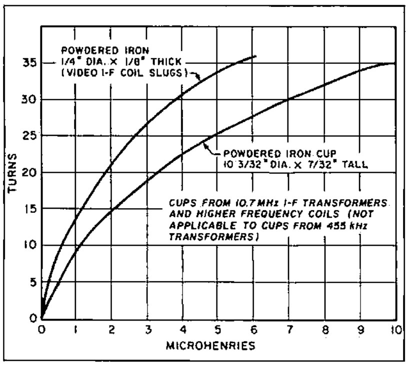


Figure 1. Approximate inductance vs. turns for toroids wound with #30 enameled wire.

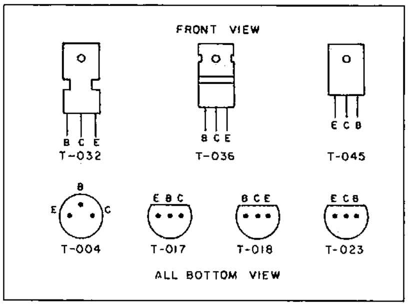

Figure 3. Transistor pin configurations.

material mix, spreading or compressing turns, and wire size can cause considerable variations in inductance. To be sure, use an L-C checker (See "Build This Simple L-C Checker," *Ham Radio*, December 1988 or "The Coil Tester," *73 Amateur Radio*, September 1990).

Cores and cups from 455 kHz transformers will yield very low Q, inefficient coils if used above 2 MHz or so. You can make a rough but effective check of core material with a grid-dip meter, provided the coils for the meter are made of tubing. Insert the slug or cup INTO the meter coil with the meter set to the frequency at which you plan to use the material. If the meter reading rises slightly, stays the same or drops slightly, the material can be used. If the meter reading drops sharply, the material is not suitable. If you are making coils to cover 160 to 10 meters, check the material at around 20 MHz. If it looks OK there it will work 160 to 10, although the circuit Q on the lower frequencies may not be quite as high as found with optimum material. RF designers use much more sophisticated methods, selecting the optimum core material for each frequency segment, conditioned on requirements for circuit Q, thermal stability, etc. (That's why the TS-940 is so expensive!)

Ferrite Slugs and Forms

Your TV set may also contain large, solenoid type coil forms tuned with ¼" diameter, hex-hole ferrite slugs for operation in the horizontal and/or vertical sweep circuits at 15.75 kHz and 60 Hz respectively. Ferrite slugs are more like glass and cannot be easily sliced. They can be used in the same manner as ferrite beads, to suppress RF on wiring. If you need short sections you can try filing or grinding to break off portions, and if you are lucky you will not end up with useless broken pieces as I generally do.

The horizontal/vertical deflection yoke positioned around the bell of the picture tube is wire-wound ferrite. Remove the wire and the ferrite may come apart or be held together with clips. When clipped together (or cemented with epoxy), the bell-like form becomes an effective, toroid type RFI filter form. Winding the AC power cord of your TV receiver or hi-fi set half a dozen turns around this core will prevent RF from getting in (or out) via this route. Ditto for the AC power cord of your transceiver or linear amplifier. For maximum effectiveness, wind on as many turns as the form will hold (or cord length will allow) and anchor them in place with twine or tape. The larger the picture tube, the larger the form, with 25" color sets yielding a form which is almost too large to hide behind a small set.

The horizontal high voltage transformer, generally housed in a separate metal enclosure will also yield useful ferrite material in "U" shaped sections bolted together, forming the transformer core. After the windings are removed the closed form can again be used for RFI suppression, as described for the yoke material.

"Another Balun Design" in *Ham Radio*, May 1982, describes the construction of an antenna balun made by winding six turns of small diameter coax on each opposing leg of the closed form. Another use for this material is the fabrication of a bifilar RF choke used for the filaments of cathode-driven linear amplifier tubes. (See "Hints and Kinks," *QST*, August 1989.)

Transistors and Diodes

Chances are, most of the equipment you salvage will come from the Far East. Although they use our color code on resistors and mark capacitors in English, transistors and diodes are a different story. Most plastic transistors will bear a letter/number identification that has no relationship to our 2N system. Here is the key to their system: Transistors prefixed with A or B are PNP, C and D are NPN, and FETs start with K. Some metal devices may use S followed by the A, B, C or

U5	7805 +5V regulator
XO1	Motorola K1160AA, 6 MHz

A blank PC board is available for $4.75 + $1.50 shipping per order from FAR Circuits, 18N640 Field Ct., Dundee IL 60118.

The 6 MHz crystal oscillator module, model XO-600, is available from Short Circuits, P.O. Box 285, Barnegat NJ 08005. (609) 698-3080.

ors, each about eight inches long, and connect one end of each wire to the proper point on the PC board; each output frequency is brought out on a separate wire. On the schematic, mark the wire colors you use, identifying each with the frequency it carries.

Testing, Testing

The pins on the oscillator XOI should be shortened by ⅛" with diagonal cutters so that the oscillator will seat snugly against its socket. Be certain the square corner on the oscillator package is at pin 1 on the socket. Do not install the other ICs yet.

Apply power, and measure the output voltage of the 7805. It should be between 4.96 and 5.5 for proper operation. Remove power and install the oscillator XO1. Apply power; then, using a frequency counter or receiver, check to see that outputs are available at 6 MHz intervals. Remove power.

Insert U1, 74LS90, in its socket and apply power. As above, check that it provides an output at 1 MHz intervals. Remove power. Insert U2 in its socket and apply power. Check to make sure it provides a 100 kHz signal at the proper intervals. Remove power. Insert U3, 74LS74, check for the 50 kHz and 25 kHz signals. Remove power. Insert U4, 74LS90 and look for the 10 kHz signals.

Caution: Always be sure power is off before inserting or removing ICs. Failure to do so may result in a destroyed IC.

Use a Blocking Capacitor

Apply power to the marker generator. Connect its output to your receiver's input. *Be sure you use a blocking capacitor (0.01 µF)!* Select the desired output frequency and locate it on your receiver. As you zero in on the desired portion of the spectrum, change the marker frequencies as you desire.

If you have followed the layout and schematic accurately, you now have an excellent crystal-controlled marker generator which covers a wide portion of the radio spectrum—and you've spent less than $10. . . even if you bought all the parts new! 73

Continued from p. 24

D and a series of numbers. Later model equipment may use Motorola transistors carrying 9000 series numbers which have no relationship to the ABCD system.

By far the easiest answer to unraveling the specifications for these devices is found in RCA's SK Series Replacement Guide. A second source is Radio Shack's Semiconductor Replacement Guide. Both of these list thousands of semiconductors with specifications and pinouts. If you are unable to get these books, see Table 1 for specifications of the more popular transistors.

You can sort out small diodes with an ohmmeter. In general, germanium types will have a lower forward resistance than silicon. Or, you can pass a small current through them (10 to 15 mA) and measure the DC voltage across the diode: 0.6 to 0.7 volts for silicon and 0.2 to 0.4 for germanium. Zener diodes are sometimes marked with 1N numbers or they may have just a single digit, such as 8, on the body, signifying an 8 volt zener. Otherwise, these can be identified by using the circuit shown in Figure 2.

RF Tuners From Car Radios

Many radios (Collins, Yaesu FT-101, etc.) use RF tuners (also called preselectors) which consist of two or more coils slug-tuned via a front panel control. This type of tuner simplifies multiband frequency coverage because it can cover a larger frequency spread more efficiently and with fewer components than a design using variable capacitors. The same form of inductive tuning is used in most automobile radios. If you are adept and patient, you can convert these to ham band use. The slugs used for the BC band cannot be used for the higher ham bands (3.5 MHz up). If your radio is AM and FM you can take the slugs from the FM section of the tuner (which won't be used) and use them in place of the AM slugs. The "Q" factor on the lower frequency bands won't be quite optimum with these slugs but they will still be very satisfactory.

The BC band coils must be stripped and rewound with 15 to 25 spaced turns to achieve an inductive range of around 1µH to 4µH tuning spread. The tricky (and difficult) part is to wind both coils identically so that the inductances track closely with slug penetration. My version varies from 1.4µH to 4µH and covers 3.5 to 29 MHz in conjunction with band-switched capacitors.

Other Components

Aside from consumer electronic products, many valuable components can be found on scrapped circuit boards sold at hamfest flea markets. I have found boards loaded with VHF power transistors, hot-carrier diodes, miniature relays, etc., for as little as 25¢ each. The law of supply and demand is tilted way over to the supply side because there are not too many of us builders and experimenters around. Join the ranks of the privileged few. 73

New AOR Scanner

1000 Channels. 8-600MHz, 805-1300 MHz

- Continuous coverage (except UHF TV 600-805)
- AM, FM and wide band FM tuning modes
- 10 Scan Banks. 10 Search Banks.
- Selectable Priority Channel
- Selectable Search Increments. 5-955KHz
- Permanent memory backup.
- 25 Day Satisfaction Guarantee. Full refund if not Satisfied.
- No Frequencies cut out.
- All normal accessories included.
- Size: 6 7/8"H x 1 3/4"D x 2 1/2"W Wt. 12 oz

An HF/VHF/UHF Marker Generator

Get on frequency for less than $10.

by J. Frank Brumbaugh KB4ZGC

Many hams operate HF as well as the 2m, 1¼m, and 70cm bands, and higher. Most marker generators hams build provide outputs only at 100, 50, and 25 kHz. This is adequate for the HF bands, but it's impossible to identify even a specific 100 kHz marker at VHF and higher. You need harmonic-rich outputs in the megahertz range to facilitate identification at these higher frequencies.

Motorola's K1160AA

The marker generator described here provides square wave outputs at 6 and 1 MHz, and at 100, 50, 25 and 10 kHz. I chose 6 MHz because its harmonics accurately mark 144 MHz, 222 MHz, 420 MHz, many points in the 70cm band, plus 450 MHz. The remaining outputs enable identification of as close as 10 kHz points in between.

The heart of this circuit is a 6.000 MHz crystal oscillator made by Motorola: the K1160AA. Self-contained in a sealed metal can, it fits a 14-pin DIP socket. It operates from a +5 VDC regulated supply and draws 65 mA. Output is a square wave rich in harmonics. It is available from Short Circuits, PO Box 285, Barnegat NJ 08005 for $1.00. The Part Number is XO-600.

See the circuit in Figure 1 and the parts placement in Figure 3. The oscillator and all other parts were obtained from Short Circuits. The filter capacitors and the resistor came from the junk box.

How the Marker Generator Works

A +5 VDC fixed regulator 7805 provides a nominal +5 VDC to the circuit, which requires 100 to 150 mA, depending on the ICs selected. The 74LS chips require much less current. Use a scrap of aluminum to make a small home-brew heat sink.

The oscillator, XO1, feeds a square wave at 6 MHz to U1, 74LS90, which is connected to divide by six. Output is a 1 MHz square wave which is fed to U2, 74LS90, connected to divide by ten. The resulting 100 kHz square wave is fed to U3, 74LS74, which is connected to divide by both two and four, producing square wave outputs at 50 and 25 kHz. The 50 kHz output from U3 feeds U4, 74LS90, connected to divide by five, thus producing a square wave output at 10 kHz.

All outputs are brought out on separate wires. They can be connected through a 1-pole, 6-position wafer switch for convenient selection to an output connector. They may also be brought out to separate connectors. Because a DC voltage also appears on these output lines, you must use a small blocking capacitor when you use the generator with a receiver.

Construction

Install the IC sockets on the PC board and solder in place. The oval shaped pin on the PC board indicates pin 1 for each IC.

Bend the pins on U5, the regulator 7805, so it will lie flat against the PC board mount, and solder it in place. Through the small hole in the tab of the 7805, drill a hole through the PC board, if desired for later attachment of the home-brew heat sink. You can add the filter capacitors now or later.

Take six insulated wires of different col-

A Parallel Port I/O Board

Control your world!

by Wally Gardiner VE6BGL

If you've recently purchased one of the new IBM PC clone computers for the ham shack, you have probably been wanting to use it to control the coffee pot, the antenna rotator, and who knows what else! This article describes how to use the parallel port, which normally connects to the printer, as an input/output port to control the outside world (see Figure 1).

The parallel port on most clone computers exits the back of your machine in a 25-pin female connector. Table 1 shows the necessary pinouts of the printer port as you face the computer. For our purposes, we can ignore all the other pins on the connector.

The computer sends data to the printer using pins 2 through 9, and with simple programs written in BASIC, we can send data to our interface board the same way. The IBM series of computers are port-oriented, and a port can be addressed easily using the OUT command. This is similar to using the POKE command to store a value in memory. Instead of appearing in memory, the value will appear on the data lines of the specified port. Using LPT2, as an example, the command OUT 632,0 would latch all of the data lines low, while a command OUT 632,5 would set data lines 2 and 0 high. Why, you ask? Binary arithmetic! Examine Table 2.

By OUTputting the appropriate decimal number, we can control which lines on the parallel port will be HIGH (+5 volts) and which will be LOW (0 volts). This even lets us control more that one thing at a time, handy for azimuth and elevation rotators for an OSCAR pass, for example. It can walk AND chew gum!

Customizing the Interface

The remaining problem is to interface the data lines coming from the computer to the real world without causing any mushroom clouds inside the machine. Obviously, we don't want 120 volts zinging around our motherboard! Take a look at the schematic in Figure 2. All this does is buffer the data line pulse by feeding it through a diode and a 1k resistor to the base of an NPN transistor, causing the transistor to act as a switch. Data bits 0 through 3 are connected to larger power transistors and monitor LEDs, and can be used to control high current items such as stepper motors, while data bit 4 is connected to a relay driver.

If the I/O board were connected to LPT2 on an XT, typing a command from BASIC, such as OUT 632,16, would cause the relay to close, while an OUT 632,0 would make it open. The relay in turn could be connected to lights, the coffee pot (through a larger relay to handle the higher current!), your rotator, or the key for your rig! So how about a practical application? Depending on the kind of keying your rig requires, the I/O will key it either through a relay, an optoisolator, or from the transistor. Consult your manual, and if you're not sure, use the relay method.

```
10 CLS
20 PRINT "Program to test LPT2 port"
30 PRINT "************************"
40 PRINT:PRINT
50 OUT 632,0

90 GOTO 50
999 END
1000 FOR TDLY=1 to 2:NEXT TDLY:RETURN
```

Listing 1. Stepper program.

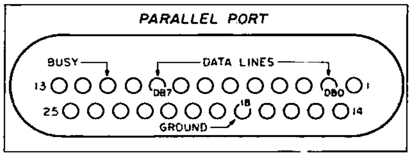

Figure 1. You can use this parallel port, which normally connects to your printer, to control more than one device at a time.

To test your interface, run the program STEPPER.BAS, Listing 1. The port addresses may have to be changed, depending on your particular machine. When STEPPER.BAS is run, all the LEDs on your I/O board should make like an old-fashioned police scanner, blinking sequentially. If the lights don't blink, troubleshoot!

Note that the port number 632 may also have to be changed depending on your computer. Other numbers to try are 888 and 956. Check the documentation that came with your machine. HINT: If your manual says something like HEX 3BC, and you want to convert that to decimal from BASIC, type: ? &H3BC and BASIC will return a value of 956 decimal.

Output Control

Now that your interface has been tested, it's time to do something with it. Enter and SAVE the program MORSE.BAS, Listing 2. This program will allow you to type on the keyboard and send Morse code either through the speaker for code practice study groups, or out the parallel port (Data Bit 0) to control the LED. The LED will blink on and off in Morse, and would make a great signaling device.

If your rig can be keyed by a transistor, the LED can be paralled with an optocoupler, and used to key

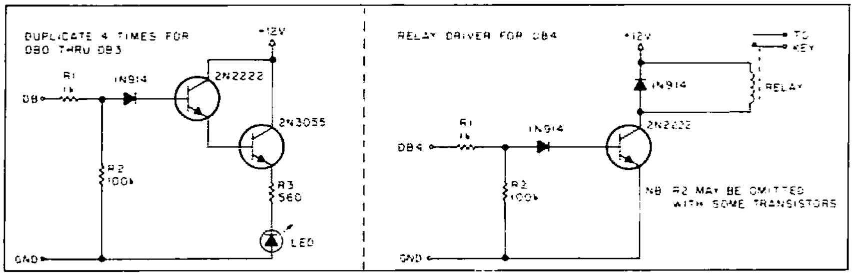

Figure 2. (a) Data bits 0 through 3 are connected to larger power transistors and monitor LEDs. (b) The relay driver for DB4.

the rig directly. If you are not sure about this, modify the program to control the relay, and use the relay contacts to send Morse. This is mandatory for older tube rigs, and anything else that normally has high voltage across the key contacts. It involves changing lines 18010 and 19010 to ?????. Darn, a quiz in the middle of the article! We want data bit 4, and only data bit 4, to be HIGH, so we would use the command OUT 632,16, where 632 is the LPT2 address and 16 is the decimal value we want to appear on the port. Therefore, lines 18010 and 19010 should both be changed to read OUT PORT,16. [Ed. Note: PORT is the variable

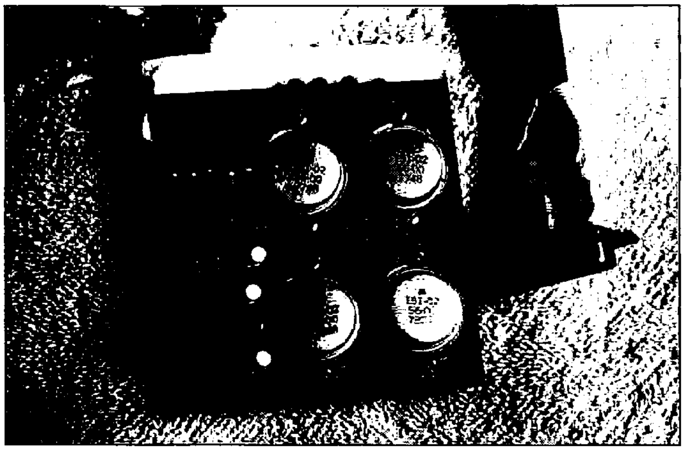

Photo. Once you've constructed your parallel interface, you're ready to experiment with it.

CIRCLE 124 ON READER SERVICE CARD

that indicates the particular port address of your machine.]

MORSE.BAS is written in simple, non-sneaky, generic BASIC, and you should be able to port it to almost anything. I have run the code practice part of the program on everything from a Color Computer to an antique Commodore PET! To adapt it to a different computer involves changing the SOUND and OUT routines to something that your computer can use. For CoCo owners, the program adapts nicely to controlling the serial port, and I would imagine something similar can be done for the Apple and C-64.

Input Detection

So much for getting stuff out of the computer. How do we get data into it? Well, it turns out that BASIC also has a command called INP for INPUT and you can use a line used such as:

1000 A = INP(X)

where X is the port address PLUS one. So X might be 889, 633, or 957, depending again on your particular system. This command will read the status of the BUSY line on the printer port, and return a value of (usually) A=255 if it's LOW, or 128 if it's HIGH. Connect a push button switch between pin 18 (ground) and pin 11 (BUSY) and run the program BUSYTEST.BAS, Listing 3. With the appropriate receive software, you are now all set to automate the CW end of the station.

Practically, however, it has been my experience that the computer between your ears is much better at decoding the 20 meter band than any machine. But you could use the BUSY line with a microswitch to sense when a rotator had reached a point, a gate had been shut, or a window was left open!

For those of you with Rube Goldberg tendencies, use the relay to turn on the coffee pot (OUT 632,16), and a thermistor connected through the BUSY line to detect when it's ready. Automatic microprocessor controlled coffee!

I'm sure you will find your own uses for the board. For those of you who despise typing as much as I do, 5¼" disks are available for $10 U.S. and an SASE. *[Ed. Note: Listings of the three BASIC programs are also available free on the 73 BBS under the 73mag SIG. The BBS number is (603) 525–4438.]* Enjoy!

Qty.	Part	Description
5	2N2222	NPN transistor
4	2N3055	NPN transistor
4	LEDs	Light Emitting Diodes
6	1N914	diodes
5	1k (R1)	resistor, ¼ watt
5	100k (R2)	resistor, ¼ watt
4	560 (R3)	resistor, ¼ watt
1	LM4	12 volt relay
1	DB25	male connector, 25 pin

Misc. assorted hardware, ribbon cable, pert board, etc.

Notes: Resistor R2 (100k) may not be necessary, depending on the transistor selected. Check the polarity of the LEDs when installing them. Relay contacts must be able to handle the current of the switched device. Don't use a miniature relay to control an arc welder! The relay coil MUST be paralleled by a diode.

You may contact Wally Gardiner VE6BGL at Box 2035, High River, Alberta Canada T0L 1B0.

73 Review

by Jeffrey A. Meyer N8AHA and Bill Brown WB8ELK

The WB2OPA LogMaster

A versatile HF logging program for the IBM PC.

Sensible Solutions
P.O. Box 474
Middletown NJ 07748
Price class: $60

The contest is over and you're the lucky op who lost the toss, and gets to organize the logs and send them in to the contest sponsor for credit. UGHHH! Making sense of the log sheets and reading the slop your group calls handwriting can certainly try anyone's patience, especially after hours of screaming phonetics and pounding brass. There must be a better way! Enter the idea of having a personal computer present during the contest to perform your logging, check dupes, and print the results in completed form at the conclusion of the contest.

To help me cope, I began looking for software programs that have the capabilities to make contesting and logging easier. My desires were simple. First and foremost, the software must be easy to understand and have a manual that doesn't resemble "War and Peace." Second, it must be flexible enough to work for different contests as well as provide duping, logging and printing functions. Finally, it must be compatible with my current computer system so that I can spend more money on ham type stuff.

The Sensible Solution

I recently ran across the WB2OPA LogMaster program by Sensible Solutions. This particular program was written specifically for HF logging and contesting, and it works on my IBM PS/2 (or any IBM PC/compatible). I read the manual and really enjoyed tinkering with the program. The inner workings revolve around easy-to-use pop-up windows which guide the user through the various segments of the program: Log, View, Search, Print, Utilities, and Quit. Each segment is well thought-out and extremely easy to learn and use. Aside from the expected Time-Call-Freq-RST-Mode logging functions, the LogMaster Includes fields for tracking and reporting CQ zones, ITU zones, states, prefixes, beam headings, starting and ending QSO times, counties and QSL functions. The contents of these various fields as well as the final log can also be viewed, modified and finally printed for contest submissions.

Getting Started

LogMaster runs on an IBM PC or compatible and needs at least 512k of RAM. You need either two floppy disk drives or one floppy drive and one hard drive. Installation is quick and easy. To run the program just enter the command "LM" at the DOS prompt.

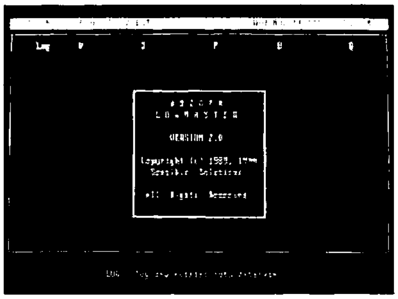

Photo A. The LogMaster main menu.

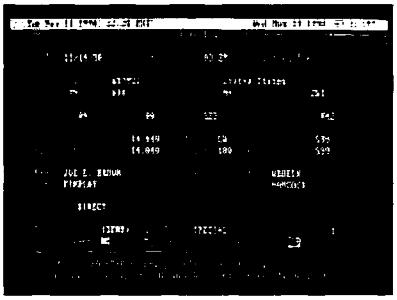

Photo B. Entering your QSO information.

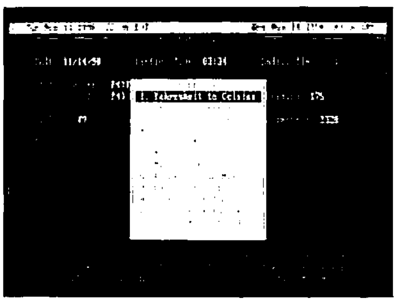

Photo C. Metric conversion pop-up window.

The first time you install LogMaster, you enter the local time zone, latitude and longitude, input power, and the directory path for your logbook file. Thereafter, you go directly to the main menu on start-up.

The main menu comes up with several categories: Log, View, Search, Print, Utilities, and Quit (see Photo A).

Access to each submenu is driven by single keystroke commands. Each command drives a series of pop-up menus which guide you easily through all the features. Hitting the ESC key brings you back to each previous menu.

Logging In

The Log section allows you to enter stations worked into your logbook database. You have two options of entry. The "Manual" selection allows you to enter calls with complete control of the time and date—useful for entering contacts made from contest logsheets, for example. The "Auto" mode automatically enters the date and time for each contact in real-time. The Log entry screen provides a lot of information about each contact, including QSL sent/received status (see Photo B). During the logging process a series of function key commands are available which really enhance an already powerful program.

One of the most useful of these is the "Notepad" function. You can literally write a full page of information describing a contact. When viewing a specific entry in the logbook, you can recall this notepad with just a function key. Other function key commands allow you to update the frequency (if using a computer interfaced radio), enable the QBICSP option (which highlights a contact if you need it for a specific reason), enable an RST-sent serial number for each contact in a contest, do dupe checking while logging, check QSO start and stop time, tag a QSO or do quick a save function (you don't have to step through ail of the log entry items). If you have a Kenwood rig with a computer interface, LogMaster will automatically enter your current transmit and receive frequency when in "Auto" mode. Other rigs should be similarly supported in future revisions.

The "Dupe" checking feature is a very flexible function. You can check dupes for callsign, country, state, CQ zone, ITU zone, or prefix. It highlights the call and beeps whenever a dupe situation is encountered. The Tag function allows you to add a specific bit of information to your logged QSO, which you can search for later. For example, if you want to mark all your QRP, RTTY, or AMTOR contacts, you can put a specific tag on them and just list out only your QRP contacts.

Another nice pop-up window is available during the logging process which is particularly useful for foreign contacts. By hitting <Alt-C> you get a metric conversion program (see Photo C)!

Viewing

The "View" menu allows you to sort out your logbook and display it in different ways.

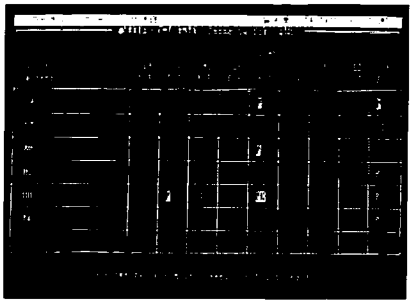

Photo D. Multiband logbook summary.

Utilities

This section allows you to customize the program to your individual specifications. Dupe checking searches can be reconfigured here and you can also select a new file path for different logbook entries (a useful feature for a specific contest entry).

I found the Statistics section particularly interesting. Selecting this submenu allowed me to look at my countries, states, CQ zones, or ITU zones worked. This display quickly gave me a multiband display of my progress in each of these categories (see Photo D). In addition, you can display QSL activity and total QSOs in this manner.

11/10/90	01:33	KA8LWR	28.680	USB	57	58	MEL	N	N	Y	N
11/10/90	01:36	K7IRK	28.636	USB	59+	59+	BOB	N	N	Y	Y

Figure. Logbook printout.

You can display the entries sorted by date, country, state, callsign, CQ zone, ITU zone, prefix, tag or QSL sent/received marks.

A note about the record-protection feature: "Protect All Fields" prevents you from changing any entry; "QSL Edit Only" allows QSL status information editing; and Edit All Fields allows complete editing. This feature adds another keystroke when you're looking for log entries, but it helps prevent you from making inadvertant errors!

I found the sorting feature of the LogMaster incredibly useful. I could literally display all of the contacts I made with just one station. If I wanted to list out only my QRP contacts, I used the Tag function.

Searching

Although similar to the "View" menu, the Search area allows you to search for partial search keys. For example, if I wanted to find my QSO with KA8WLV but forgot his suffix, I would search for all calls beginning with KA8 until I found him.

Printing

This menu is handy if you'd like a hardcopy printout of your logbook (see the Figure). You can print out your whole logbook or start from a particular date. Of particular interest to contesters is the "Awards Dupe Sheet". This option prints out your log sorted in callsign order.

Useful Utilities

In addition to LogMaster, you will find two utilities on the diskette. Merge allows you to merge two logbook databases into one logbook.

And you can print your own QSLs! QSL labels and even QSL cards can be printed with this handy utility. It uses your logbook database to print out specific cards right on your printer.

Impressions

I found the WB2OPA LogMaster very easy to use. The versatility of sorting your logbook by different search patterns and the notebook area made it extremely useful. I found that if anything, there were too many categories for each logbook entry. Fortunately, there is a quick save function key. You should also be careful to enter the FULL path for each new logbook, or you could inadvertantly erase a previous log.

I was pleasantly surprised with all of the functions and the ease of operation of the HF LogMaster. I only wish it could be used for VHF/UHF contacts as well. The LogMaster really shines when you consider the time saved in entering and maintaining a logbook, particularly the log sheet paper jam that builds up during a contest. ■

Kenwood's TM-941A Triband FM Transceiver

Three for the price of one.

Kenwood U.S.A. Corp.
P.O. Box 22745
2201 E. Dominguez Street
Long Beach CA 90801-5745
Phone: (213) 639-4200
Price Class: $1200

First there were single-band FM transceivers, then came dual-band rigs. Now there's a three-band radio, Kenwood's new TM-941A triple-band FM transceiver that covers 2 meters, 70 centimeters and 23 centimeters. With this one rig you can operate on the 144, 440 or 1200 MHz amateur bands.

Kenwood has managed to squeeze three transceivers into one small package measuring 5.91"W x 1.97"H x 6.89"D. It feels like three transceivers, though, weighing in at over four pounds.

What the TM-941A Offers

The TM-941A is designed for 13.8 VDC operation at a maximum of 11.5 amps (high power transmit on 2m). It comes with several standard accessories, including a mobile mounting bracket, DTMF microphone, DC power cable, an extra fuse, a 56-page instruction manual, warranty card, and an assortment of miscellaneous hardware. Also included is a nice feature that's recently become popular on a number of other mobile rigs: a detachable front panel. With either the optional PG-4K or PG-4L interconnect kit, the transceiver body can be located remotely from the front panel. This is especially handy in some of today's cramped smaller autos, and provides an added measure of security in any vehicular installation.

Three RF output power levels are available on 2m and 70cm: HI output on 144 MHz is 50 watts, MID is 10 watts and LOW is around 5 watts. The power levels on 440 MHz are 35, 10 and 5 watts respectively. Two power output choices are available on 1200 MHz, 10 watts (HI) and 1 watt (LOW).

As shipped from the factory, the TM-941A transmit frequency ranges are 144–148 MHz, 438–450 MHz and 1240–1300 MHz, and modifications for MARS/CAP are possible. Receive coverage on 2m is 118–174 MHz (including AM reception in the aeronautical bands, although the instruction manual makes no mention of this). The 70cm and 23cm receive frequencies are the same as the transmit frequencies, but a modification is available that will expand the reception coverage to 400–475 and 1210–1330 MHz.

The three transceivers are about as separate as is possible in one radio. Kenwood has provided each band with its own volume and squelch control, antenna connection, display area on the front panel LCD, and external speaker jack. The radio's single internal speaker is common to all three bands, and there is a fourth speaker jack available that can route the three bands' combined audio to a single external speaker. You could conceivably have as many as four external speakers connected–one for each of the three separate bands, and one for the combined audio.

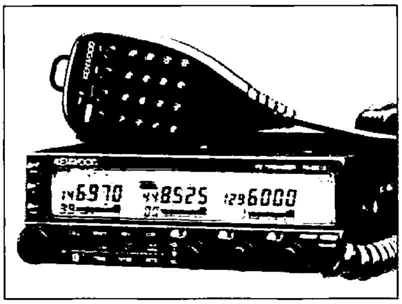

Photo A. The Kenwood TM-941A tribander.

This separate functionality means that you can simultaneously receive on all three bands, and even configure the rig for cross-band repeat operation (I wasn't able to test this feature and there's no mention of how to do it in the instruction manual).

The Features

The TM-941A is packed with all the features and capabilities typical in modern microprocessor-controlled transceivers. Space restrictions preclude a review of all of them (the instruction manual is 56 pages long, not including the schematic and block diagrams), so I'll highlight a few of the major ones that are either standard or are available as options.

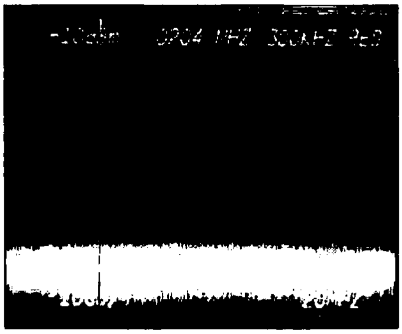

Photo B. Spectrum output from the TM-941A, representative of all three bands' performance. (The photo is of a 2 meter TX signal on a Tektronix 7L14 analyzer.)

CTCSS encoder: There are 38 subaudible tones included, selectable from the front panel. The rig I tested did not have the optional TSU-7 CTCSS decoder, but the module is easily installed in a socket accessible behind the front panel.

Dual-tone squelch system: If the optional DTU-2 module is installed, this function allows what Kenwood describes as selective calling. When activated, the receiver's squelch will not open unless the transmitting station sends a three-digit DTSS code matching what you have programmed in your radio. You can also transmit programmable codes for individual or group calling. The paging function of this option lets you display the three-digit code of the calling station on the front panel display. Seven memories are available for storing your own radio's code, the calling station's code during receive, and group codes or the codes of other stations.

Repeater offsets: Automatic offsets that conform to the ARRL's band plan are standard on 2m, but you can override this and enter your own offsets, if necessary. Offset selection on 70cm and 23cm must be done manually.

Tone alert: This provides an audible alarm to let you know when someone is transmitting on a frequency being monitored. When activated, this function won't actually break squelch to allow you to hear the transmission. It just beeps when a signal is received, and keeps track of the elapsed time of the signal's transmission.

Automatic power off: How many times have you forgotten to turn your mobile rig off after you left the car? Popular in many HTs, this capability in the TM-941A will turn the radio off after two hours and 59 minutes of inactivity.

Time-out timer: If you are on the long-winded side and keep timing out repeaters, this function will be especially useful. You can select 3, 5, 10, 20 or 30 minutes (or OFF for no limit) as the amount of continuous transmission time allowed before the radio automatically switches back to receive mode. A beep will let you know when the rig has reached the limit you've chosen.

Measurements Made Easy

When *73* contacted me about reviewing the Kenwood TM-941A tribander, I thought it might be appropriate to evaluate a state-of-the-art rig with a state-of-the art test instrument. I called Motorola and obtained one of their new R-2600A communications system analyzers.

The R-2600A sells for a little over $10,000, putting it out of the reach of most hams, but its versatility and many capabilities make it ideal for those involved with two-way radio servicing in the 400 kHz to 999.9999 MHz range. The 33 pound package takes the place of several pieces of test equipment. This all-in-one box serves as an RF signal generator (−130 to 0 dBm), a sensitive AM/FM measurement receiver (2 μV), scanning receiver, spectrum analyzer, duplex offset generator for servicing repeaters, frequency counter, AC/DC voltmeter, oscilloscope, wattmeter (0.1 to 125 watts), signal strength meter, frequency error meter, SINAD meter, distortion meter, FM deviation and AM percent of modulation meter, sweep generator, audio generator and a signaling simulator. This last feature includes the capability of encoding and decoding PRIVATE LINE (PL), DIGITAL PRIVATE LINE (DPL), and single tone sequences as well as multitone sequences including DTMF, two-tone paging, 5/6 tone paging, International Select V, and 20 Tone General Sequence.

The analyzer is based around Motorola's M-68000 16-bit microprocessor, and makes use of digitized screen bit mapping, softkeys and windowing, and permanent storage of common test setups. The R-2600A can even be connected to an external PC or printer.

I was able to conduct almost every test on the Kenwood using the R-2600A. In fact, except for 1200 MHz operation and actual on-air tests, the TM-941A spent most of the rest of its evaluation time connected to the communications analyzer.

Automatic band change: Suppose you have the TM-941A set to transmit/receive on 2m, but you're also monitoring 70cm and 23cm. If you wanted to transmit on, say, 23cm you would have to manually select that band to be able to transmit on it. With the A.B.C. function activated, the radio will automatically do that for you when a signal on another band is received.

Automatic lock tuning: This function is available only on 1200 MHz, and operates somewhat like an AFC. When turned on, the ALT will detect the drift in frequency of either you or the other station and automatically shift the TM-941A's frequency to compensate.

Fixed detect output: The internal microphone connector (it's behind the front panel) is an eight-pin telephone-type jack. One of its pins is labeled RD and can provide receive audio from the selected TX/RX band. By using the CONT SEL function, this terminal will be activated and can be used for packet operations.

Dimmer: The front panel illumination can be set to one of four levels of brightness.

Scanning: Here's where the magic of microprocessors really shines! The TM-941A includes "Band Scan," where an entire band is scanned in the VFO mode. "Programmable Band Scan" lets you scan a range between selected upper and lower frequency limits. "Memory Scan" covers those memory channels that are stored in a band or bank and have not previously been locked out. "Call/VFO Scan" alternately scans the call channel and a chosen VFO frequency, and "Call/Memory Scan" alternates between the call channel and the memory channel last used. "Auto Memory Scan" automatically memorizes a busy frequency (it's stored in an empty channel in bank five) while scanning a band. Kenwood also included two types of scan hold/resume functions: "Time Operated Scan" and "Carrier Operated Scan." In "Time Operated Scan" the radio will stop on a busy frequency for about five seconds, then continue scanning. In "Carrier Operated Scan" mode, the radio will stop on a busy frequency and remain there until the signal is no longer being received. After a two second pause with no signal present it will resume scanning.

Memories: Seven pages alone in the instruction manual are dedicated to the various memory functions available in the TM-941A and their operation. The rig includes a lithium battery to retain the memories when primary power is not available, and you can reset the main memories and VFO memories independent of each other. The radio has 100 memory channels for each band, divided into five banks of 20 channels.

For normal channels, each memory is capable of storing operating frequency, offset, CTCSS tone and status, frequency step, shift status, REV status, DTSS code and status, and last operation paging memory number (with the optional DTU-2). For odd split channels, the same information is stored, except for shift status and REV status. A call channel memory for your favorite frequency is also available for each band.

Adjacent memory banks can be linked to form one larger bank, and all banks can be linked. It's also possible to perform memory consolidation, where memory channels are rearranged to optimize memory scan operations. This rewrites the active memory channels sequentially, from the lowest to highest channel, without any blanks in between. Memory shift will copy the contents of a memory channel to the VFO.

Miscellaneous: Kenwood has included a "Demonstration Mode" that is described in the manual as capable of providing "a short demonstration of the capabilities of the TM-941A." I found that this was not particularly useful, since it doesn't really show how the radio works or how to use it. It's actually not much more than blinking lights and a flashing display that ends with "enjoy your hobby" before repeating all over again. When you cancel this function, the VFO memories are cleared (but not the main memories). Other features include the ability to set the beeps that the radio emits when buttons are pressed to one of eight loudness levels, including OFF; three radio LOCK functions allow disabling all of the microphone buttons (except PTT), the front panel buttons and tuning control, or all controls except the ON/OFF switch, volume and squelch. Frequency step selection includes 5, 10, 15 and 20 kHz on 2m, all of those plus 12.5 and 25 kHz on 70cm, and 10, 12.5, 20, and 25 kHz on 23cm.

In receive mode the radio is specified to draw less than 1.2 amps, and in transmit mode (high power) less than 11.5 amps on 2m, 10 amps on 70cm, and 6 amps on 23cm. F3E (FM) operation is by reactance modulation, and spurious outputs are rated −60 dBc or more on 2m and 70cm, and −50 dBc on 23cm. Maximum deviation is ±5 kHz, and transmitted audio distortion is specified at 3% or less at 60% modulation.

The receivers all use double conversion. The first IF on 2m is 10.7 MHz, 70cm is 21.6 MHz, and 23cm is 59.7 MHz. All three bands use a 455 kHz second IF. Sensitivity for 12 dB SINAD is rated at better than 0.16 μV, and squelch sensitivity less than 0.1 μV. Kenwood specifies −6 dB selectivity at more than 12 kHz on all three bands, and −60 dB selectivity at less than 24 kHz on 2m and 70cm and at less than 36 kHz on 23cm. Audio output is rated at more than 2W (8 ohm load at 5% distortion).

Table 1. RF Power Output Summaries

2 Meter Output Power (Watts)

Setting	144 MHz	146 MHz	148 MHz
HI	45.7	42.6	38.9
MID	11.4	12.0	12.5
LOW	5.2	5.3	5.4

70 Centimeter Output Power (Watts)

Setting	438 MHz	444 MHz	450 MHz
HI	33.8	33.8	32.3
MID	11.2	10.7	10.4
LOW	3.9	3.8	3.8

23 Centimeter Output Power (Watts)

Setting	1240 MHz	1270 MHz	1300 MHz
HI	10.5	10.0	9.5
LOW	0.95	0.95	0.79

Antenna connections are made to the three short cables on the rear of the TM-941A. Female UHF connectors are provided for both 2m and 70cm, and a female N connector for 23cm. The cables for the two higher bands also include plastic boots that slip over the connectors for additional protection (they're not weatherproof, however).

The front panel contains a number of controls to operate the radio. Included are a tuning control knob, volume and squelch knobs for each of the three bands, power ON/OFF, a front panel release button, and 14 other push-button "keys." Many features are controlled by functions embedded in the various keys, accessible by pressing certain combinations of keys. For example, pressing and holding the "F" key for about one second until the key indicator flashes, then pressing the "REV" key, enables the beep volume selection.

The front panel LCD display is quite impressive. It includes separate areas for each of the three bands, and each band display area has its own S/RF meter, on-air indicator, plus a host of symbols for the various functions that may be active on each band. It's possible to completely turn off one or more of the three bands, and doing so will blank the respective area of the LCD after "off" has been displayed for about 10 seconds.

The DTMF microphone supplied with the TM-941A has the standard 16 tones, PTT, UP/DOWN buttons, CALL, VFO and MR (these three duplicate the functions of their counterpart on the radio's front panel), and a PF (programmable function) button. The PF button can be programmed to perform one of 10 transceiver functions, including a MONITOR function that's not on the front panel.

Test Results

Actual power consumption was comfortably less than what Kenwood specifies. At 13.8 VDC, maximum current draw while transmitting on 2m was 9.2 amps (HI), 5.9 amps (MID), and 4.28 amps (LOW). On 70cm the figures were 7.3 amps (HI), 3.78 amps (MID) and 2.71 amps (LOW); on 23cm they were 4.18 amps (HI) and 2.52 amps (LOW). In receive mode on all three bands, the current draw was 940 mA with the cooling fan off and 990 mA with the fan running. One departure from conventional VHF/UHF mobile rigs that I've used in the past is a small fan attached to the rear cooling fins. It comes on during transmission and shuts off automatically after a minute or two in receive mode.

Using the Motorola R-2600A communications analyzer (see the sidebar), 2m receiver performance was found to be 0.15 μV sensitivity for 12 dB SINAD, 0.22 μV for 20 dB quieting, and 0.07 μV for squelch sensitivity. At 1.25 watts audio output, distortion was 1.2 percent. The receiver's performance on 70cm was equally good, with 0.17 μV sensitivity for 12 dB SINAD, 0.21 μV for 20 dB quieting, and a squelch sensitivity of 0.07 μV. At 1 watt audio output distortion was 1.3%. I was not able to make these measurements on 23cm, due to the upper frequency limit of the communications analyzer.

When I measured RF output power, I chose three frequencies in each band—one at the lower end of the band, one in the middle, and one at the upper end. The results are summarized in Table 1.

Photo B shows the purity of the TM-941A's transmitted spectrum. On both 2m and 70cm the only measurable spurious emission was the second harmonic, which was greater than 65 dB down. The Tektronix spectrum analyzer I was using has an upper frequency limit of 1800 MHz (below the second harmonic of 23cm), and within that range I could not find any spurious signals from the 23cm transmitter.

Frequency accuracy on 2m averaged a little more than 300 Hz low, and 1.3 kHz low on 70cm. I didn't measure this parameter on 23cm. Transmitter deviation with normal speech was 3 to 4.5 kHz, with the microphone two to three inches away. On-air signal reports, both simplex and through local repeaters, were rated very good by several hams. (I called up a local 2m ATV net with the TM-941A instead of my usual rig, and received glowing reports there, too.)

Comments

Kenwood has done a nice job with this radio. Squeezing three separate transceivers into one relatively small package was a formidable task, but they did it right. Even the broadband reception capability on 2m produced few problems. I listened to signals in the aeronautical bands, public service bands, etc. and found received quality to be quite good. This kind of design is sometimes susceptible to intermod, though. While monitoring certain 2m ham frequencies, I occasionally heard a paging transmitter sneak through.

The cooling fan is a nice touch; it's not too loud, but it is noticeable in the shack. In a mobile environment, vehicle and road noise easily mask it. I noticed that the radio remains warm to the touch in just receive mode, due to the amount of electronics inside the case. The temperature did not appear to increase significantly while transmitting, thanks to the cooling fan.

Very Few Complaints

I really had trouble finding things I didn't like about this radio. The use of a UHF connector on the 70cm antenna lead is not to my liking, and the demo mode in the radio really serves no useful purpose. Output power on 2 meters in the HI position was a few watts low on the rig I tested, but everything else was right about where it was supposed to be. A couple of items, like AM reception capability on aeronautical frequencies and crossband repeater operation, were not included in the instruction manual but should have been. I also noticed that the front panel latch button didn't always snap into the locked position when the panel was replaced; sometimes I had to manually lock it. The only other thing I didn't like was having to return the radio after the evaluation! The real question, though, is how long before they put this triband technology into an HT? 73

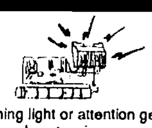
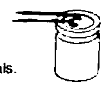
**** New ** FLASH UNIT**



This NEW compact flash unit comes from a U.S. manufacturer of cameras. Unit operates on 3 Vdc and measures 2 1/2" X 1 1/4". Ideal for use as a strobe, warning light or attention getter. Complete with instruction on how to wire.
CAT# FSH-1 $3.75 each 10 for $35.00

Special New Reduced Price PHOTOFLASH CAPACITOR



Rubicon CE photoflash capacitor. 0.79" dia. X 1.1" high. These are new capacitors that have been prepped with 1.4" black and red wire leads soldered to the terminals.
210 Mfd 330 Volt **CAT# PPC-210**
$1.25 each • 10 for $11.00 • 100 for $100.00
Large quantities available. Call for pricing.

FLASHING L.E.D.

Diffused L.E.D. with built in flashing unit. PULSE RATE: 3 Hz @ 5 Volt/20 ma. Unit continually flashes when 5 Volts is applied. Operates between 4.5 Volts and 5.5 Volts. T 1 3/4 size. IDEAL AS AN INDICATOR.

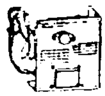
RED CAT# LED-4
GREEN CAT# LED-4G
YELLOW CAT# LED-4Y
$1.00 each • 10 for $9.50 • 100 for $90.00

HEAVY-DUTY NICKEL CADMIUM "C" BATTERY

Yuasa 1800C
Special purchase of new, rechargeable nickel-cad batteries. 1.2 volts, 1800 mAH.
PRICE REDUCED ON 10 OR MORE.
CAT# HDNCB-C
10 pieces for $42.50 ($4.25 each)
100 pieces for $375.00 ($3.75 each)

POWER SUPPLIES

5Vdc 3 AMP



ACDC Electronics #5N3-1
New, prepped power supply with wires and connectors soldered to the inputs and outputs. Open frame style. 4.94" X 4.03" X 2".
Input: 115 Vac. UL and CSA listed. Regulated.
CAT# PS-53 $10.00 each

12 Vdc 5 AMP

ACDC Electronics # 12N5 or equiv.
Input: 100-240 Vac (wired for 115 Vac)
Output: 12 Vdc @ 5 amps. Open frame style.
7" X 4 3/4" X 3" high. Regulated.
CAT# PS-125 $37.50 each

24 Vdc 2.4 AMP

Power-One Inc. #HC-24-2.4
Input: 115/230 Vac (wired for 115 Vac)
Output: 24 Vdc @ 2.4 amps. Open frame style.
5.62" X 4.87" X 2.50" CSA listed.
CAT# PS-2424 $30.00 each

The Three-Terminal Regulator

Multiple uses in one package.

by E.R. Doubek N9RF, P.E.

Since the three-terminal voltage regulator was first developed to permit local voltage regulation, it has found a place in both commercial and home-built products. With improved regulation, the circuit designer doesn't have to run heavy power leads between the power supply and the load or design for remote sensing at the load. Not only does the three-terminal regulator do a nice job of regulating voltage, it also ensures a lower power supply impedance, which helps to handle transient current spikes. See the table for a list of the most common, low-cost, and readily available three-terminal fixed and adjustable voltage regulators.

Normally, these regulators do not require additional components to generate a regulated voltage. The device is simply placed so its input terminal is connected to a source of voltage at least 2 volts above the regulator's rating as long as you don't exceed 35 volts. At voltages above 35 volts, the unit may be destroyed. The output terminal delivers the voltage corresponding to the ratings shown in the table. The third terminal, GND, is a reference for the regulator. Normally, a current under 10 mA flows in the GND lead. It may be connected to a reference voltage source, the output of another regulator, or to ground.

Advantages of the Regulator

Figure 1 shows possible connections for different uses. If the regulator is located some distance from the power source, a 0.25 to 1.0 µF capacitor may be connected from the input terminal to ground. This improves transient response and helps prevent regulator instability. You can put a capacitor from 0.01 to 1.0 µF from the output terminal to ground to help control the spikes most logic circuits generate. Keep in mind that the source of input power must be capable of supplying a greater voltage than the output of the regulator under a load of at least 1.5 amps. The regulator is internally protected to prevent damage in case the unit becomes too hot or the load too high.

Another reason for using three-terminal voltage regulators is that they protect against shorted components on a circuit board that could be damaged because of insufficient fusing and small printed circuit conductors.

The LM317T voltage regulator, adjustable for voltages from 1.25 to 37 volts, requires a few external components. See Figure 5 for a typical circuit application. It has a line regulation of 0.01%/volt and a load regulation of 0.1%. The ripple reduction is typically about 80 dB, a significant figure.

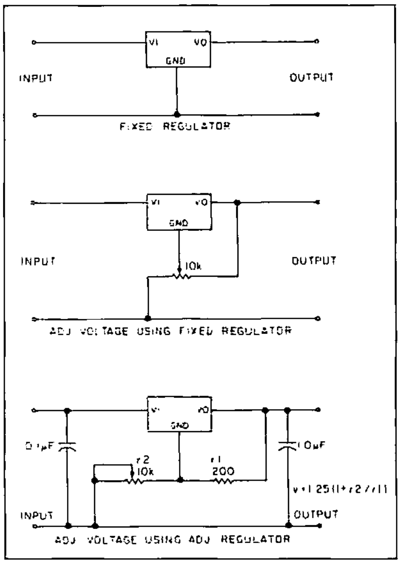

Figure 1. Three-terminal regulators may be fixed or adjustable.

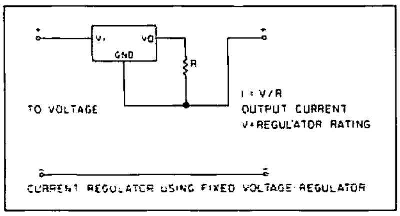

Figure 2. Add a resistor and this connection, and you can use your fixed regulator as a current regulator.

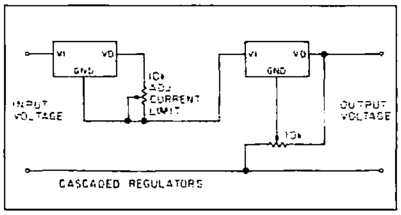

Figure 3. Cascading a current regulator and a voltage regulator adds flexibility and circuit protection.

Regulating the Current

By adding a resistor and the connection shown in Figure 2, the same fixed regulator can be used as a current regulator. With this circuit, you can calculate the value of the regulated current from this simple equation: **R** = **V/I**, where **R** is the value of the programming resistor, **V** is the value of the regulator voltage, and **I** is the value of the desired current level. With this circuit feeding a lamp load, the life of the bulb can be greatly increased, since the inrush current with a cold filament is limited.

You can also use this circuit for battery charging, when you want to charge at a fixed rate regardless of the terminal voltage to the battery.

This circuit has also been very successfully used as a stable bias source for transistor circuits and as a driver for LEDs. In many cases, the LED output is more easily controlled by regulating the current through the diode instead of controlling the voltage impressed across the diode. This difference may be especially important in circuits for battery operated infrared-emitting devices.

If the resistor is adjustable, the circuit can nicely control the speed of a small DC motor (of the type often used in some instruments) without a large wattage series resistor.

Charge a capacitor from a constant current source and the result is an interesting capacitor ramp generating circuit. The ramp is linear. You can also use this circuit to provide a constant current source for making a 4-terminal resistance measurement.

Continued on page 58

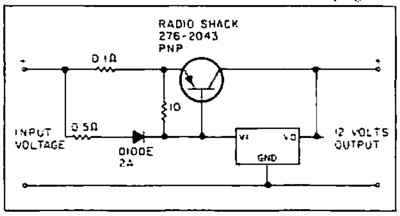

Figure 4. Here's a better way to handle increased current.

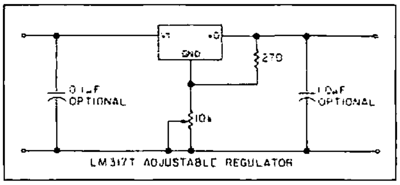

Figure 5. The LM317T adjustable regulator requires some external components.

Rose Parade Mobile

A high-tech HF remote station.

by David R. Corsiglia WA6TWF

The 101st Tournament of Roses Parade provided a unique opportunity for amateur radio to contribute to the 1989–1990 parade theme, "A World of Harmony."

The hundreds of hams who provide communications support to the parade each year were joined this time by Bill Fedde KC6GSD. Bill contacted hundreds of hams by operating a mobile station while riding in a vintage car in the parade. (KC6GSD will again operate Rose Parade Mobile. See the sidebar.) The son of Don Fedde, the 1989–1990 Tournament of Roses president, Bill was seen by the four million television viewers and one million spectators who lined Colorado Blvd. in Pasadena, California, on New Year's Day.

Photo A. Bill Fedde KC6GSD working Rose Parade Mobile. (Next to driver, waving hand.) Notice the headset and whip antenna.

Bill used a concealed hand-held radio broadcasting to an ultra-sophisticated remotely controlled transceiver coming out on 28.333 MHz. These remotely controlled transceivers are connected to a repeater through a low-band, computerized interface controller. Most stations contacted said that Bill's signal was S9+ through the remote station. Many stations contacted in Europe had excellent signal readings.

The TWF Super System

The plan originated when Bill, a recent graduate of Gordon West's Radio School, mentioned to Gordon WB6NOA that he would be participating in the Rose Parade with his father. Gordon had recently joined the TWF Super System, a remote base system with the capability of going in on 440 MHz and coming out on any band from 80 meters to 440 MHz on sideband or FM. With this technology and equipment available to Bill, the serious planning began.

The TWF system has three of these remote systems in operation in the Los Angeles basin. Each station operates with the most up-to-date equipment, giant antenna systems, and kilowatt amplifiers. The station that Bill used for the parade is on a one-thousand-foot hill overlooking the parade route. It uses Kenwood TS-940, 711, and 811 transceivers, and a 4-element KLM tribander on 10, 15, and 20 meters (see Figure 4 and Photo B).

Photo B. David Corsiglia WA6TWF demonstrates the TWF Super System.

As a new ham, Bill had never participated in operating a DX or special event station before. Gordon tutored Bill and conducted mock contesting drills. Even though hundreds of stations called Bill, everyone was courteous and the check in's proceeded in a well-organized manner. Three net control stations helped hold the frequency before the event started and kept a log of all stations heard. Reel-to-reel tape recorders were used to log the whole event so no one was left out.

Bill and Gordon sent press releases to more than 40 news-gathering organizations. The 90 television cameras along the parade route offered on-the-air close-up pictures of the president's car. Bill could be seen next to the driver with his headset on, contacting hams throughout the world.

To counteract the problem of the dual-band hand-held radio running out of power, a 4 Ah gel cell battery was installed and an external power cord was used. A mag mount antenna was camouflaged with flowers by a volunteer group from Holland that decorates the officials' cars in the Rose Parade each year.

The World at Your Fingertips

The brain of the TWF system is a low-band interface controller designed and built by K6QE Systems. This controller allows any mobile operator to control the band, mode, and exact frequency, and also to rotate the antenna to the desired setting from a hand-held radio or mobile using touch-tone commands. Other features include automatic antenna switching and frequency scanning.

The audio is so good that most amateurs contacted through the system don't realize they are talking to someone using a remote transceiver. K6QE Systems had already adapted the controller for the Collins KWM-380 and Yaesu's FT-980 and 767. Now it has adapted the controller for the Kenwood 940.

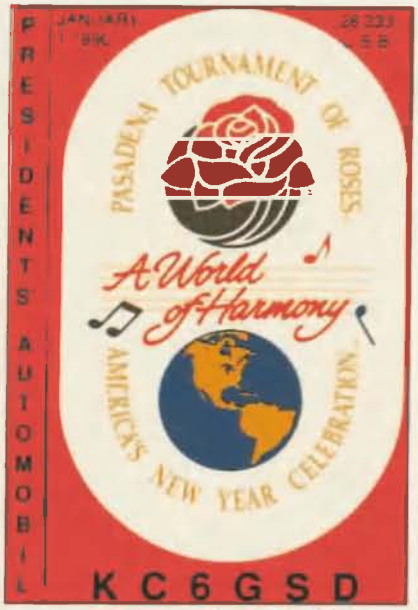

Figure 1. QSL card from 1989-1990 Rose Parade Mobile.

Jim Gilliam, designer of the K6QE Systems' low-band interface, says he is going to standardize the adaptation on the Kenwood radios for future units.

One of the main difficulties with having a computer control a worldwide transceiver is keeping the computer-generated noise out of the receiver. A special set of shielded boxes had to be custom-manufactured to enclose the commercial Micro-Mint computer board.

Repeaters connected to a low-band interface system have allowed many hams in the Los Angeles basin encumbered by antenna restrictions access to a superb worldwide station at their fingertips. They can make rare DX contacts as well as enjoy general ragchewing.

Nancy Bucher N6XQR is one user of these new remote stations. She says it doesn't make sense for her to invest a lot of money in an expensive HF radio because she lives in a very restrictive town house project and can't put up any decent antennas. So she joined a repeater group that has a low-band interface, and now she can come out on 20 meters, just like the big DXers. Nancy uses only a small hand-held 440 MHz radio.

Dan Fort AA6LM, operating bicycle mobile, talks to hams all over the world on 1 watt. Dan is a member of the TWF Super System which allows him to go into the repeater on 440 MHz and be rebroadcast out on all the HF frequencies using kilowatt amplifiers.

If you have an interest in this technology, please write me at the address given at the end of this article, or call me at (714) 535-5528.

For inquiries on Bill Fedde's operation in the up coming Rose Parade, please write Bill Fedde, 394 Jones St. Ventura CA 93003, or call him at (805) 643-1817.

Figure 2. Ultra Comshack 64 Repeater Controller with some of the various boards available.

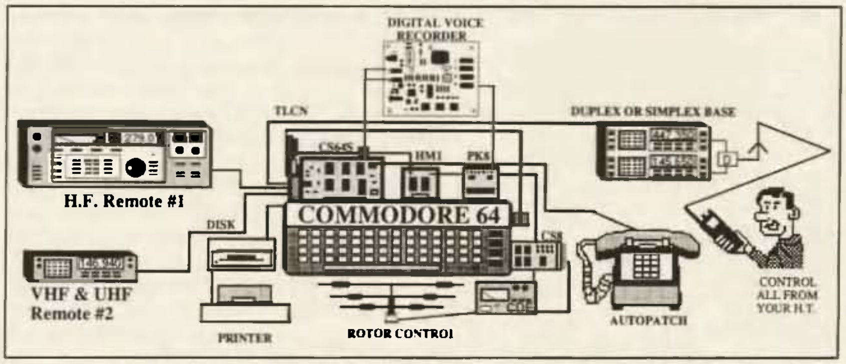

Figure 3. Block diagram of Ultra Comshack 64 Repeater Controller.

The Super Station

A hand-held radio plus a repeater with a remote transceiver equals a super station. The remote system Bill Fedde uses for the Rose Parade is part of the new wave of sophisticated repeater systems that are connected to amateur HF radios.

These repeater controllers are very smart and can perform just about any tuning function of the remote HF radio that an on-site human operator can do. For example, Bill can push a few touch-tone buttons on a 440 MHz handheld and come out on 20 meters USB and talk halfway around the world.

Groups of hams around the U.S.A. are pooling their resources and putting up these stations in areas such as industrial parks, where they are unencumbered by antenna restrictions. One such system in Santa Ana, California, is using a Kenwoood TS-940 transceiver. This group was able to erect a 6-element KLM tribander on one tower and a 3-element 80 meter beam on another tower not subject to residential zoning ordinances.

Although many manufacturers make repeater controllers that activate UHF and VHF radios, very few companies at this time sell units that control HF radios. Two companies that do are Engineering Consulting and K6QE Systems, both located in Southern California.

The Engineering Consulting Ultra Comshack 64 line of controllers consists of a series of circuit boards (Figures 2 and 3). You can pick and chose from various boards for the features you want. The basic starter board is $379.95, but a super deluxe system in a 19" rack enclosure with every option would run approximately $2,500.

The Ultra Comshack 64 will work with most computer-controlled radios on the market today. A combined dual-remote control system allows two transceivers to be controlled at the same time. For example, one for for HF and another for VHF. The control operator has tremendous capabilities to remotely change any parameter of the station, such as length of phone call, time-out timer,

etc. The system, which runs on 12 volts DC, can be remotely programmed by touch-tone, packet, or modem.

The Ultra Comshack 64 can use any FM radio as a primary input/output device. A repeater is not necessary. You can use a simplex channel or a dual-band transceiver in a crossband mode. The Ultra Comshack 64 includes complete programming, but it's an experimenter's delight because you can custom-tailor hundreds of commands with macros. You can truly have it your way with an Ultra Comshack 64. If you want one thousand autodial numbers and a talking S-meter, you can have it. The list is endless!

K6QE Systems manufactures a deluxe low-band interface controller. This is a turn-key system; just take it out of the shipping container and hook up the supplied plug-in cables to your transceivers. You can have up to five transceivers. There are also cables for the repeater and a rotator control box. Turn it on, and you're on the air.

The unit has a voice storage command feedback system that sounds so real you would swear that a human voice is speaking to you. The controller will not let the user transmit out-of-band accidentally, and it knows USB is normally used on 20 meters, although it can be forced to LSB. The K6QE low-band interface uses a built-in commercial micro-mint computer. The unit operates off of 110 volts AC and works only with the Kenwood line of radios (TS-940, 911, 811).

Features Common to Both Units

Both units have a telephone accounting system which allows individual access codes for each user. The control operator can request a hard copy printout via modem of the past month's telephone activity including, but not limited to, the number dialed by each access code, length of call, date, and time. Both units also have full low-band remote functions you can access from any touch-tone phone. For example, you could be at work pretending to be on an important business phone call and really coming out on 20 meter USB, working that rare DX contact you would have missed otherwise.

Both manufactures supply excellent documentation and a 90-day warranty. K6QE Systems offers a one-hour VHS video on their system, and on remote bases in general. The $39.95 charge for this tape is refundable if you purchase the unit.

Comshack users can tune in to the Comshack Remote Base Net that meets Sundays 1100 PST on 14.275. Bob Blumenkranz NI6R is net control.

For more information about the Comshack system contact: Engineering Consulting, 583 Candlewood St., Brea CA 92621, tel. (714) 671-2009; for information about the K6QE controller contact: K6QE Systems, 2180 W. Crescent Ave., Suite F, Anaheim CA 92801, tel. (714) 991-1439.

KC6GSD Goes One Better

This year Bill Fedde KC6GSD will be working Rose Parade Mobile again, but from a parade float this time. Bill has arranged to hitch a ride on the Rand McNally float, and he will be able to make contacts throughout the journey down the Rose Parade route.

Alinco Corporation has donated a DR-590T dual-band mobile transceiver with remote tuning head for this special station. This type of radio was needed because of the limited mounting facilities on board the float.

Bill wants to have complete access to the tuning controls of the radio so he can switch from 2 meters simplex (144.330) for working local spectators with their hand-held radios, to 440 MHz to access a K6QE systems remote station to come out on 28.333 MHz.

Gordon West WB6NOA is helping Bill with a special headset for the parade. A dual--

Work a Rose Parade Float!

This year the Tournament of Roses will have a "super station" operator (KC6GSD) on board one of the floats, so be sure to tune in to 28.333 MHz and talk directly with the station yourself. "Alinco is working closely with David Corsiglia WA6TWF to set up the right type of equipment for this operation, so our signal into the remote base on UHF should be very loud and clear," says Gordon West WB6NOA.

Classroom comments usually go like this: "Right, Gordo, you're telling me this handheld is reaching all the way to a station in Japan—sure, tell me more . . . ."

To the newly licensed amateur radio operator, capabilities of remote-based operation are best summed up by one student who said, "Amazing, simply amazing!" And it is. How many times have you walked down a busy street, chatting on your handheld, in QSO with a station thousands of miles away? The remote base makes this all possible.

The "WA6TWF super system" also provided Gordon West ham class students with 10 meter code practice covering all of Southern California and, on most evenings, blanketing the entire central states and East Coast with rock-solid signal strengths.

Every Monday evening between 6 p.m. and 8 p.m. Pacific Time, an on-the-air code class is offered on 28.333 MHz. Simply dial up 28.333 and tune down a few kilohertz until you find the familiar sounds of a Morse code class on the air. But unlike Morse code generated for on-the-air practice, Gordon West narrates on the same frequency that the code is being sent on. And since the code is sent at 28.333 in the Novice code and voice portion of the band, narration is indeed practical and possible.

Gordon West, recent ARRL "Instructor of the Year" award recipient, best known for his humorous code and theory training tapes, says, "We will send code for about three minutes, then ask any student on 10 meters for a read-back. It really gets everyone involved. And when conditions are just right, it's not surprising to get a read-back from stations down in South America or as far west as New Zealand.

"This unique style of code class also allows me to stop and answer questions students may have. Nowhere else on the dial can anyone find this type of 'two-way' code class, and I think we have hundreds of one-way listeners, too, tuning us in on the UHF band with their programmable scanners."

West uses an equalizer and audio system to combine both modulated CW and voice. The code is generated by a Bencher paddle tied into an AEA Morse Machine, and the MM-3 may also take code directly from a Radio Shack Model 100 lap-top computer. The MM-3 has the latest revision which allows the computer-generated input to be sent at 15 or 18 wpm character rates. The ARRL uses 18 wpm character weighing, where most other examination teams use the more traditional 15 wpm character weighing. Either way, the MM-3 or Gordon West on the paddles can easily handle both types of CW.

A Kenwood 721 transmits the voice and modulated CW on the 440 UHF band to a repeater 60 miles away on the Palos Verdes Hill. The repeater retransmits the voice and code on UHF, and also feeds the big Yaesu base station. Via the WA6TWF remote-base system, the base station may be remote-controlled to transmit on 10 meters, and also to listen on 10 meters, to feed the received student responses back down on the UHF link. This allows West to monitor both 10 meters locally and 10 meters from the remote base. A 70-foot tower and tribander, located at an altitude of 1400 feet above sea level, commands a signal that can be heard in the Los Angeles basin as well as thousands of miles away. Beam heading is generally to the east, but if enough students are calling in from Australia, New Zealand, and Japan, the beam may be remote-controlled to the west.

"The system works terrific—about the only thing that causes us a problem is a nearby military radar installation that puts a buzz on the UHF link. And from time to time we have someone come on the 10 meter band to inform us that our CW sounds a little strange. After we let them know it's modulated CW coming from a UHF link, the 10 meter operator can get the idea of what's going on, and generally stays tuned in.

"And it's our guests tuning into code practice that makes everything really work well—many times guests will transmit their own version of code practice, and our students love it. We welcome everyone to not only listen, but to take part in this 2-hour code class, on the air," says West.

West occasionally uses the WA6TWF remote base for his Tuesday morning contact with the "CQ All Schools Net" found on 28.303 MHz (every Tuesday and Thursday at 12:30 p.m. EST). He links up with Carole Perry WB2MGP, and the coast-to-coast stations provide schools all over the country with a look into ham radio in live operation.

It's best summed up, as one of Gordo's students has said before, "Amazing, just awesome amazing!"

band antenna will be camouflaged in the flowers of the float.

A commemorative QSL will be available to anyone who hears or works Bill. For your QSL, send a self-addressed stamped envelope to: 102 Tournament of Roses (KC6GSD), 391 South Orange Grove Blvd., Pasadena CA 91184.

So on January 1, 1991, New Year's morning, turn your radio to 28.333 MHz and give KC6GSD a call. Bill will be detailing his progress down Colorado Blvd. Turn on your TV, also, because he will point out when he is in front of the TV Cameras. 73

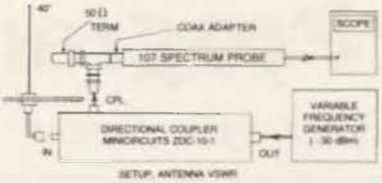
evaluating an
ANTENNA (MATCH)

FIG. 9



10dB per DIV

100 µV

frequency 100MHz

The degree of match between a 50 Ω source and an antenna is obtained with the set-up illustrated in fig. 9. The tuning, Q, and reflection loss are available. The CPL output with either an open or direct short on IN is plotted as the fwd line in fig. 10. Then the cable to the antenna is attached, and the scope photo of fig. 10 results. The difference between these lines is desired. The scope indication of "37 dB" forward, "12 dB" reverse, indicates the reflected loss is down 25 dB at 68 MHz; (1.1 VSWR) 1/320=0.3% of the applied power is reflected or about 99.7% of the available power is radiated (or at least absorbed) by the antenna. Conversely, 99.7% of the received power is applied to a 50 Ω receiver. Since the probe can "see" a low level, only a low radiated signal is required. The discrete lines are signals received by the antenna. The logarithmic response allows evaluation of good matches.

73 Review

by Bill Clarke WA4BLC

The ELNEC Antenna Modeling Program

Let your computer design your next antenna!

ELNEC
Roy Lewallen W7EL
P.O. Box 6658
Beaverton OR 97007
Price Class: $50 postpaid. Specify whether or not your computer has a coprocessor.

The wind is blowing and the rain is pelting the old radio room window, but today I am going to design and test a new antenna. Of course I'm not going out in that wet weather to do antenna work. And, I'm not even going to cut a wire or solder a connection.

How, you ask? Simple. I'm going to model my newest antenna idea on a computer. How about that, folks—a use for a ham's computer other than packet!

Enter MININEC by J.C. Logan and J.W. Rockway of the Naval Ocean Systems Center, a comprehensive antenna modeling program. Roy Lewallen W7EL has used the fundamental computation portion of this program to produce ELNEC, an antenna modeling program for the IBM-PC computer and its clones. Roy began writing ELNEC over two years ago for his own purposes, saw its value to other hams, and introduced it to the public in May 1990.

The ELNEC Program

ELNEC is a computer program for the modeling and analysis of radio antennas. Basically, modeling consists of the generation of the antenna's far-field pattern (radiation pattern). This includes gain, which can be plotted in the typical ARRL-type grid style or presented in tabular form. (The latter is for folks who don't have graphics capabilities.)

If for no other reason than using ELNEC, get a graphics card and monitor for your computer. The first time you use it will more than pay for this cost. After all, you can get an "el cheapo" board and monochrome monitor for under a hundred dollars.

Features

ELNEC is user friendly. It uses a menu-based system that is easy to understand and interact with.

All outputs of ELNEC can be printed, giving you a hard copy of your efforts for later use and analysis. ELNEC's features include the ability to analyze forward gain, front-to-back ratio, beam width, 3 dB pattern points, side lobe information, SWR (50 or 75Ω systems), voltage, current, impedance at source points, and current distribution along the wires.

A unique feature is its TOTAL pattern generation. A total pattern is a combination of the vertical and horizontal components of the radiation pattern, and shows exactly what you may expect in real operation.

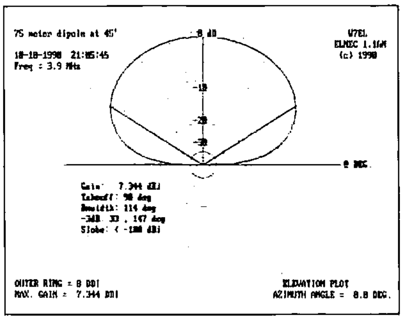

Figure 1. This 75 meter dipole at a height of 45 feet shows a typical elevation pattern. Note the straight lines within the pattern—they are from the ANALYSIS feature and depict the 3 dB beam width. Printed just to the lower left of the pattern's center is the analysis showing beam width information. Specifically, the −3 dB points of 33 and 147 degrees. Note that the pattern is labeled in the upper left corner for future reference.

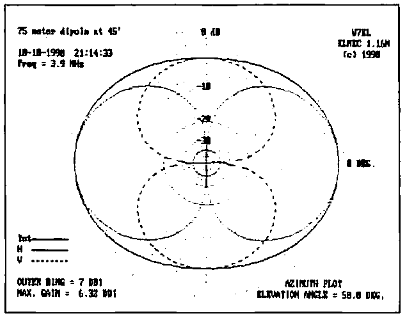

Figure 2. The same 75 meter dipole in a combination plot showing horizontal, vertical and total patterns. They are based on an elevation angle of 50 degrees, taken from within the 3 dB beam width of Figure 1. Of particular importance is the TOTAL pattern, a combination of vertical and horizontal fields.

Simple and complex antennas can be modeled, as can structures such as towers and walls, and the surrounding ground characteristics can be introduced. The combinations of these factors can produce surprisingly accurate far-field patterns.

Although most types of antennas can be modeled, program coding limitations of MININEC cause some minor limitations shared by ELNEC and other MININEC-based systems. Specifically: Closely spaced wires such as transmission lines are difficult to model (however, they are possible); you cannot determine the efficiency of a ground radial system; and impedances given for horizontal antennas lower than 0.2 wavelengths will not be correct. However, far-field patterns will be accurate.

A Small Package

ELNEC comes in two forms, one for the computer with a math coprocessor, and the other for the poor folks like me that have no coprocessor. Installation in either case is a snap. Just make a backup of the original disk and use that backup as your operating disk. Of course, as there is no copy protection used in ELNEC, you can install the system on your hard drive.

The program's documentation file is located on the distribution disk and should be printed and read **BEFORE** you try to use ELNEC.

ENSETUP is a short set-up program that allows some parameters to be modified during installation. These specifically include printer type, file paths, date format, and color selections.

Included in the instructions is a "test drive" to lead you through what ELNEC can do. It is based upon a 20 meter dipole 30 feet in the air. These instructions run for several pages in the manual and will allow you to touch and feel that dipole in every conceivable manner via ELNEC.

After the test drive is completed, you will probably wish to proceed with antennas of your own design.

Roll Your Own

All antennas designed for ELNEC are based on straight wires (of any size definable) placed on a three dimensional grid (X, Y, and Z three dimensional axes). Loops and circles are modeled as combinations of many straight wires. Using graph paper will aid you during the first few tries, which will show you how really easy antenna modeling is.

Let's take a dipole as an example. A good starting point would be the dimensions, which in this case are going to be cut for 3.9 MHz, and the height will be 45 feet. Using the XYZ grid, start at 0,0,45 (meaning in the center of the imaginary or real graph paper at a height of 45 feet). Next, enter the end of the dipole as

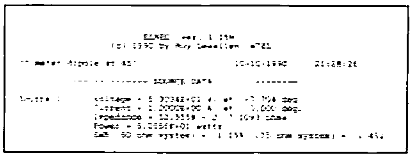

Figure 3. Source data for the 75 meter 45-foot-high dipole shows voltage, current, impedance, power, and projected SWR.

0,120,45 (notice the antenna is 120 feet long and goes from the center of the graph towards the top). The feedpoint would be entered as the source in the form of a percentage from one end of the wire to the feedpoint, in this case 50%.

Now select the type of plot you want for the dipole, azimuth or elevation, and press ENTER to calculate (see Figures 1, 2, and 3).

Observations from Use

Most of my modeling has been over what ELNEC refers to as "real ground." This allows you to customize the ground parameter of the program with your actual ground conditions (conductivity, etc., as referenced in the *ARRL Handbook*). Modeling can be done over perfect ground or in free space. I prefer to see what the real world operation of the antenna will be, so my modeling is over real ground.

While using ELNEC, and similar programs, I have found they all spit out gain figures that are extremely enticing to the uninitiated. For example, look at Figure 4 (20 meter, 3-element beam at 70 feet) and you will see the gain figures in the lower left corner. Pretty impressive, huh? Don't you believe it! That 12.88 dBi can be very misleading, just as the claims of some antenna manufacturers can be misleading.

ELNEC bases its gain figures (as do the antenna manufacturers) on dBi, decibel gain relative to an isotropic source. These figures are as theoretical as is the isotropic source, but they do provide a standard point with which to compare antennas.

For a real look at what this beam antenna can do, model a simple dipole at the same location (height) for use as a reference. Next, check the dipole's gain of 7.63 dBi (Figure 5) against that of the beam (12.88 dBi). The difference will be the expected improvement using the beam versus the dipole. Of course, that gain is only exhibited in specific directions, as shown in the pattern of Figure 4.

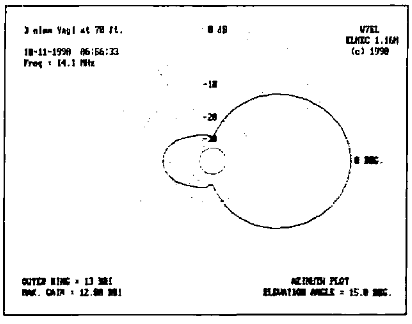

Figure 4. Total pattern of a typical 3-element yagi cut for the 20 meter band. Note the gain figures and angle of the plot.

Remember, the object of a directional antenna is to concentrate your signal (received and transmitted) to planned horizontal and vertical directions.

All-Purpose Antenna

In the hunt for the illusive all purpose antenna, I always think of the center-fed zepp. The version modeled here, using ELNEC, is 60 feet on either side of the feedpoint and is horizontal at 45 feet in the air. It is fed with 450Ω ladder line.

On 75 meters the antenna behaves as a dipole. However, as the frequency is increased, there is some directional gain.

The 17 meter plot of the zepp (Figure 6) shows how the directional pattern appears at 15 degrees elevation, which is excellent for DX. Of course, the pattern can be oriented to favor any specific geographical area simply by moving the antenna's azimuth position.

Other antennas, such as the Carolina Windom from the Antenna Works and the G5RV,

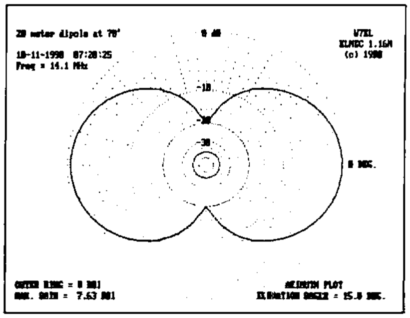

Figure 5. A dipole can be used as a standard of comparison when modeling experimental antennas and will tell you immediately if you are winning or losing the battle. Note the gain figures and angle of the plot. The dipole is placed at the same height as the beam it is being compared with.

exhibit similar pattern characteristics and are excellent for use on all bands.

An Experimental Antenna

In my personal search for an antenna for 75 meters that would reach from my New England QTH into the far southeastern part of the U.S., I designed a directive array using a dipole at 40 feet with a sloping 75 meter delta loop 20 feet behind it. The loop is 88 feet on each of its three sides and is fed in the center of the section that parallels the dipole. The parallel (to the dipole) section is at 35 feet and the far point is at 10 feet. Figure 7 shows the resulting plot at 50 degrees elevation (the plot holds from 40 through 60 degrees). Compare the plot and figures with Figure 2.

This antenna is still theoretical, as I have yet to put it up. Such is the problem of moving from one QTH to another.

Likes

1. ELNEC is considerably faster in operation than similar programs I have used in the past.

2. Print drivers are included in the ELNEC system, making "screen dumps" unneces-

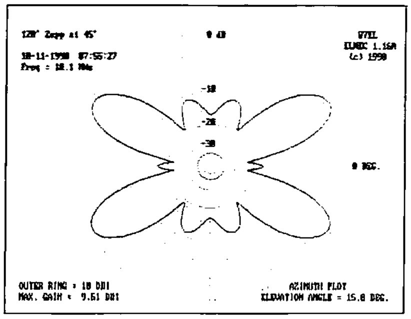

Figure 6. The zepp as it appears on 17 meters (a dipole cut for 17m would produce a similar plot as Figure 1).

sary for printing hard copies.

3. There is no copy protection (see comments later in this article).

4. The guarantee is "like it or leave it." If you're not satisfied with the program, your money will be refunded.

5. On an EGA or VGA color display you can select the colors that will be used to display various patterns (horizontal, vertical, total, etc.). CGA and monochrome displays offer no color option with ELNEC.

6. The ANALYZE feature of ELNEC quickly determines beam widths and 3 dB directional (horizontal and elevation) limitations.

7. Minor changes to parts of an antenna's description do not require complete recalculation by ELNEC.

Dislikes

1. ELNEC, in the version tested, does not save plots to files. You have to recalculate each time you wish to review a specific antenna. I make printed copies of each design, so this isn't a major inconvenience.

2. The times to complete calculation estimates (shown on the screen) are not accurate.

Copy Protection

ELNEC gets a big "Thumbs Up" for NOT being copy protected! Although it is copyrighted material, the purchaser may make copies for backup use only.

For my personal applications, I find programs that use any form of copy protection to be a nuisance at least, and disastrous at worst. Being able to make workable backup copies of purchased software is very important, as disks do crash and programs do get destroyed. *Continues on page 54*

Recommendations

Do I recommend ELNEC to my fellow hams? Yes! After testing hundreds of designs, I do recommend ELNEC. However, I also offer these caveats:

ELNEC, and other complex antenna programs, require a reasonable understanding of expected RF patterns and basic antenna design. They cannot be expected to answer all antenna questions within the first few hours of operation.

Additionally, when you begin designing antennas you will find yourself making many changes and more and more calculations. The result is that you will be spending more time on the computer and less time on the radio. You will be conspicuous by your absence from the bands. 73

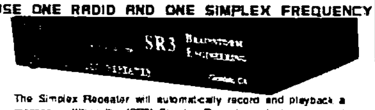
SIMPLEX REPERTER

USE ONE RADIO AND ONE SIMPLEX FREQUENCY



The Simplex Repeater will automatically record and playback a message. When the (SR3) Simplex Repeater detects a carrier it will begin to digitally record the audio being received by the radio you have connected it to. When the carrier drops, the SR3 stops recording, and key's the radio (PTT) and transmits the audio it just recorded. This allows two or more mobiles to have a simplex conversation, when they are not in range of one another, but in range of the simplex repeater site.

Low-Cost Mag-Mount

Plus a complete mobile antenna system.

by Phil Salas AD5X

For less than $25, you can have a mag-mount antenna base with low-loss coax, a 144/450 MHz dual-band antenna, a 13" 10 meter antenna, and a half-wave 825–890 MHz cellular antenna. How?

Recently I was looking through an electronics parts catalog (Marlin P. Jones & Associates, tel. 407-848-8236) and found high power ferrite toroid magnets with attached steel base plates for use as magnetic mounts for mobile antennas. They were only $2.75 each. I'd been wanting a mag-mount base with BNC connector so that I could attach my HT antenna to it while mobiling. This looked like a good foundation at a good price. Constructing the mag-mount led to antenna experimentation and construction.

Magnetic Mount Construction

See the Parts List for the parts you can order from Marlin P. Jones & Associates. You'll also need to buy an 8-32 x ⅜" brass screw and two ⅞" copper pipe caps, for a total of less than 50¢, from your local hardware store. The two pipe caps are shown in Figure 1(a). One has a ⅞" outside diameter and the other has a ⅞" inside diameter. One will slip inside the other.

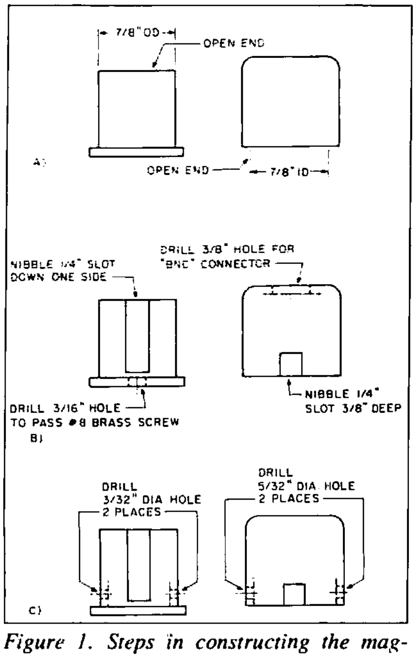

Figure 1. Steps in constructing the mag-mount.

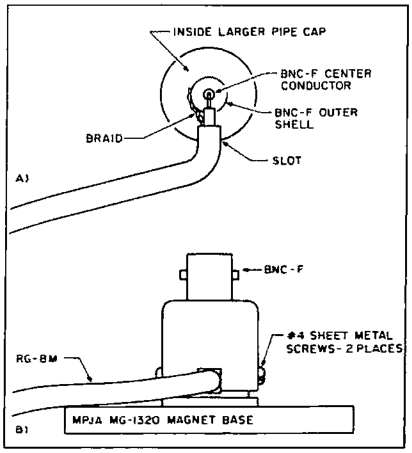

Figure 2. Installing and securing the coax to the mag-mount.

Nibble a ¼" slot ⅜" deep in the larger pipe cap as shown in Figure 1(b). Nibble a ¼" slot all the way down the side of the smaller pipe cap. Next, drill a ⅜" diameter hole in the center top of the larger pipe cap for the female BNC connector, and a 3/16" diameter hole in the center of the bottom of the smaller pipe cap for the #8 brass screw. Insert the brass screw so that its head is inside the pipe cap, then solder it in place. Be careful not to get solder on the outside threads of the screw.

Now drill two 5/32" holes near the bottom of the larger pipe cap, as shown in Figure 1(c). Slip the large pipe cap over the smaller pipe cap, align the slots, and mark positions for two holes in the smaller pipe cap. Remove the larger pipe cap and drill two 3/32" holes in the smaller pipe cap.

Insert the female BNC connector in the ⅜" hole in the top of the larger pipe cap, attach its mounting screw, and tighten in place. Now strip ½" off one end of a 14-foot length of RG-8M coax cable. Unravel the braid and twist and tin the braid and the center conductor. Refer to Figure 2(a). Rest the coax cable in the slot in the larger pipe cap and see where you can make the braid come in contact with the outer shell of the BNC connector. Tin the connector shell at this point. Now solder the center conductor of the RG-8M cable to the center conductor of the BNC connector. Tin the connector shell at this point. Now solder the center conductor of the RG-8M cable to the center conductor of the BNC, and solder the RG-8M shield to the outer shell of the BNC.

Now slip the larger pipe cap (with the RG-8M cable attached) over the smaller pipe cap, and push them together so that the small holes in the base are in line. Screw two #4 x ¼" sheet metal screws through the holes and tighten. Finally, pass the brass screw threads through the magnet base and tighten in place with a #8 lockwasher and nut, as shown in Figure 2(b).

To finish the assembly you need to attach the BNC crimp-on connector to the other end of the RG-8M cable. You'll find that the stranded center conductor of the RG-8M cable is too big to fit into the center pin of the connector. Just cut off all but three strands, then insert these strands into the center pin and solder them in place. Crimp the outer shield collar in place, as in Figure 3.

I used a hot glue gun to seal up the gaps in the base where the coax cable exits from the

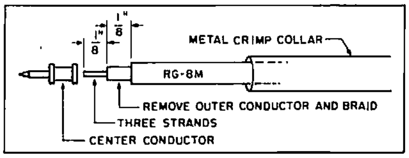

Figure 3. Crimp the outer shield collar in place, and you're finished.

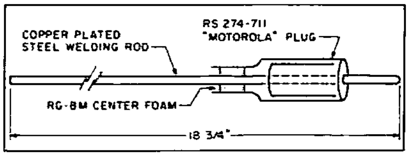

Figure 4. Dual-band 2 meter/450 MHz whip construction.

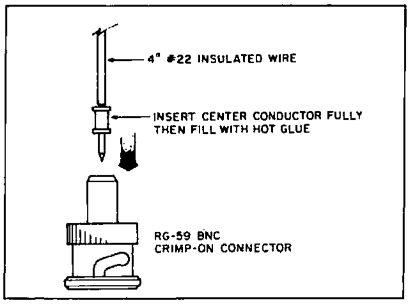

Figure 5. BNC adapter for the 10 meter antenna.

copper caps. I also put a bead of hot glue around the lip between the two copper caps.

Your mag-mount base is now complete. You can attach your HT antenna to this base and get significantly better performance than you can from using the HT antenna alone from within the car.

144/450 MHz Dual-band Antenna

I thought I could probably get better performance with an antenna larger than the 6" antenna on my FT-727R HT. Since a ¼-wave antenna at 2 meters should be close to a ¾-wave at 450 MHz, I decided to find a compromise length that would work for both bands. The result is shown in Figure 4.

This antenna is made from a piece of 0.09" (3/32") diameter standard copperplated steel welding rod. The rod costs about 20¢ for a 36" length. Use a file to round one end of the rod so that it will slip into a Motorola-type automotive radio connector (Radio Shack part number 274-711). Before sliding the rod into the connector, tin it well. Unless the end of the welding rod is well-tinned, you'll have difficulty soldering the rod into the connector.

Once the rod is soldered into the connector, press a ½" length of the center foam insulation from a piece of RG-8M over the welding rod and slide it so that it supports the welding rod in the connector as shown. Cut the welding rod to 18¾", as shown in Figure 4. Now insert the connector into a male BNC to female Motorola adapter (RS# 278-117). Place a piece of ½" heat shrink tubing over this assembly and heat it. When it has cooled, you will have a rugged antenna assembly.

With these dimensions, the antenna has less than 1.5:1 VSWR at 445 MHz, and less than 2:1 at 146 MHz. You can vary the length slightly if you wish to favor one band over the other, but you'll find negligible improvement in performance. In any case, performance will be significantly better than with the HT antenna alone.

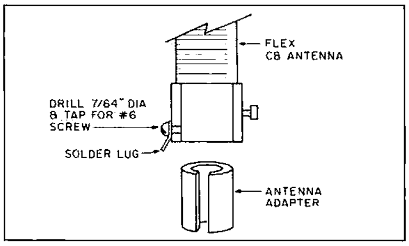

Figure 6. Modification of the CB walkie-talkie antenna mount. Drill a 7/64" hole close to the bottom of the antenna base and tap it for a #6 screw.

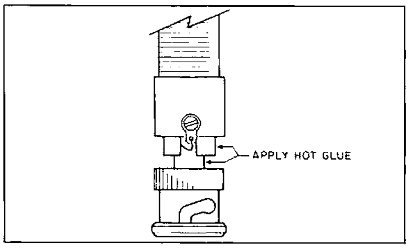

Figure 7. Attaching the BNC connector to the 10 meter mobile antenna.

13 Inch, 10 Meter Antenna

I have a converted CB rig in my car for 10 meters. Naturally, I wanted a small antenna for this rig, one that would be secure at highway speeds, so that I could attach it to the mag-mount. Radio Shack sells a flexible CB walkie-talkie antenna (RS 21-980, for $7.95) which, with a little work, will cover part of the 10 meter band.

Since we have to interface with a BNC connector, let's start with building the BNC adapter for the antenna. Refer to Figure 5. Solder a 4" length of insulated wire to the center pin of an RG-59 crimp-on connector. Insert the center pin/wire combination into the connector and fill the sleeve with hot glue to keep the center conductor pin firmly in place.

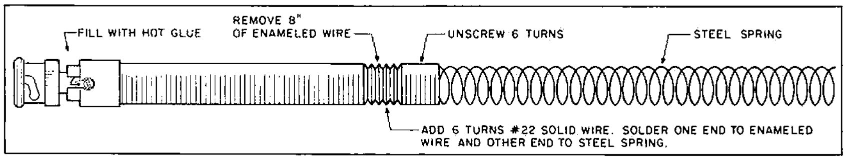

Figure 8. Modifying the Radio Shack CB walkie-talkie antenna for 10 meters.

Referring to Figure 6, drill a 7/64" hole close to the bottom of the antenna base and tap it for a #6 screw. Use a 6-32 x ¼" screw to attach a solder lug to the base at this point. The plastic antenna adapter is supplied with the flexible CB antenna.

Refer to Figure 7. Slip the plastic antenna adapter over the BNC connector and bend the center conductor wire down along the antenna adapter slot. Slip the flexible antenna base over the antenna adapter and tighten the thumb screw on the antenna base to hold the assembly together. Solder the wire to the solder lug on the base. Finally, use a hot glue gun to hold everything firmly in place.

Now for the antenna modifications. Using a sharp knife, split and remove the entire insulating outer cover of the antenna. Refer to Figure 8. Unsolder the enameled wire from the base of the steel spring. Unwrap 8" of the enameled wire and cut it off. Spread the remaining enameled wire over the full length of the nylon rod and hold it in place with electrical tape. Keep the wire tight. Now carefully unscrew the steel spring six turns. Solder a piece of #22 bare copper wire to the end of the enameled wire and wrap this wire along the threads in the nylon base that was exposed when the spring was unscrewed. Solder the other end to the base of the steel spring. Now it's time to adjust the antenna.

Mount the antenna on the roof of your car, using the mag-mount. This antenna is pretty narrowband, so I'd recommend optimizing it for a 200 kHz spread. In my case, I optimized it for the 28.3–28.5 MHz range. Using an SWR meter, check the SWR at the low, mid, and high end of the frequency range you want. This is the only antenna requiring an SWR meter.

The antenna should still be resonant too low in frequency so you'll see your lowest (though still high) SWR at the low frequency end. Now unsolder the wire at the base of the steel spring and screw the spring in ¼ turn. Resolder the wire (after clipping off the excess) and check the SWR. Keep doing this, using no more than ¼-turn increments until you're able to center up the SWR over the frequency range you're interested in. That is, you should have the lowest SWR at your center frequency and the SWR at the edges of your frequency band should be about the same. In my case, I was able to achieve a 2:1 SWR at 28.3 and 28.5 MHz, and a 1.5:1 VSWR at 28.4 MHz.

Finally, use pieces of ½" and ⅝" heat shrink tubing to cover the entire antenna. I also used a blob of hot glue to seal the top end of the antenna.

This antenna works surprisingly well. I can reliably work all over the U.S. and occasionally even make international contacts. It's tough competing with high power and big antennas when trying to work DX, but occasionally I get lucky.

Cellular Antenna

Why would a ham need a cellular phone? Well, you can reliably make and receive calls no matter where you are. Also, it is necessary for any type of business calling. Cellular phones are pretty impressive performers, and once you have one, you don't know how you ever got along without it. So, how about a cellular antenna for your mag-mount?

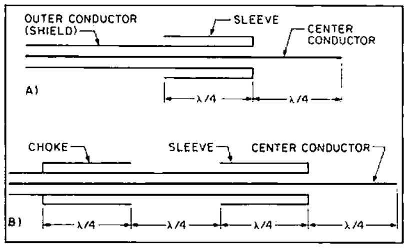

Figure 9. (a) The sleeve antenna, a simple coax-fed ½-wave. (b) Making a choke to keep the rest of the coax feed from being excited.

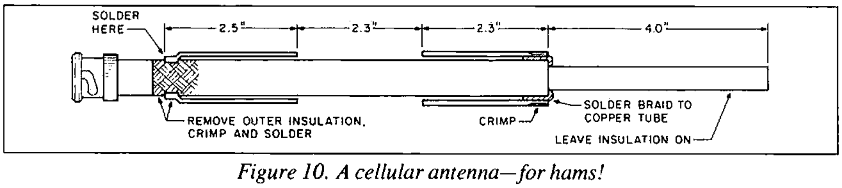

Figure 10. A cellular antenna—for hams!

Mag-Mount Parts List

Cat. #	Qty.	Description
MG-1320	1	Ferrite Magnet
RC-0561	3	Crimp BNC/RG-59
RC-0507	1	BNC-Female Panel Mount
3142-HE	2 ft.	½" Shrink Tubing
3143-HE	2 ft.	⅝" Shrink Tubing

The total for the above was $8.70. MPJ&A has a minimum order of $10. I recommend you buy two extra RG-59 crimp connectors. Marlin P. Jones & Associates, tel. (407) 848-8236.

The cellular frequencies cover 825–845 MHz and 860–895 MHz, approximately. The cellular phones transmit in the low end of the band and receive the cellular base stations transmitting in the upper end of the band. I decided to build a ½-wave antenna for this band.

The sleeve antenna is a simple coax-fed ½-wave antenna. See Figure 9(a). Basically, it's no more than a ¼-wave whip with the image provided by the ¼-wave sleeve folded back over the coax cable. By placing another ¼-wave sleeve a ¼-wave away from the open end of the sleeve, you make an excellent choke that keeps the rest of the coax feed from being excited by the signal and causing pattern degradations. See Figure 9(b).

I designed the antenna for the center of the cellular band (859 MHz). The antenna lengths are calculated as follows:

1/4 wave @ 859 MHz = 2952/859
= 3.5 inches

The velocity factor for RG-8M coax is 0.66, so:

1/4 wave (adjusted) = 0.66 x 3.5 = 2.3 inches

I constructed the antenna as shown in Figure 10. Obtain a one-foot piece of ⅜" diameter copper tubing from your local hardware store and cut 2.3" and 2.5" lengths of this tube. Cut a 12½" length of RG-8M coaxial cable. Remove 4" of the outer insulation from one end. Unbraid the outer conductor braid, trim it to about ½" and fold it back over the remaining outer insulator. Slip the 2.3" long copper tube over the braid as shown, crimp it in place with an F-type TV connector crimping tool, and solder the lip of the tube to the braid.

Now, remove 1.6" of outer insulation from the other end of the RG-8M and slide the 2.5" copper tube over this end till the two copper tubes are separated by 2.3". Crimp the end of the 2.5" long tube over the bare outer shield and solder as shown. Attach an RG-59 crimp-on connector to this end of the cable. Finally, cover the antenna with ½" heat shrink tubing and shrink it to provide a nice looking, rugged cellular antenna. I also sealed the top end of the center conductor and the interface between the center conductor and the sleeve with hot glue.

Cable Comparisons

Freq.	RG-58 loss/100 ft.	RG-8M loss/100 ft.
50 MHz	4.0 dB	2.2 dB
100 MHz	5.3 dB	13.0 dB
200 MHz	8.0 dB	4.6 dB
400 MHz	12.0 dB	7.5 dB

RG-8M, at 25¢ per foot, is only a nickle a foot more than RG-58. RG-8M low-loss, 52-ohm cable is significantly better than RG-58, and it has the same dimensions as RG-59 (so you'll find use for the extra RG-59 crimp BNC connectors). You can obtain RG-8M at Radio Shack, part number 278-1328.

I optimized the SWR for transmitting in the lower portion of the band—that's why the center conductor whip is longer than a ¼-wavelength. With the dimensions shown, I achieved better than a 1.5:1 SWR in the 825–845 MHz end of the band.

Well, there you have it—enjoy your new car-top creations. 73

You may reach Phil Salas AD5X at 1517 Creekside Drive, Richardson TX 75081.

Fixed and Adjustable Voltage Regulators

LM317T	1.5–37 volts	1.5 amps	40 volts input max.*
7805	5 volts	1.5 amps	35 volts input max.
7812	12 volts	1.5 amps	35 volts input max.
7815	15 volts	1.5 amps	35 volts input max.
7824	24 volts	1.5 amps	40 volts input max.

These regulators can be used over a temperature range of 0 to 70 degrees Celsius.
The current ratings may vary, depending on manufacturer and degree of heat sinking.
Other units available from suppliers cover voltages from 2 to 24 volts.

*Input/output differential voltage limited to 40 volts max. The LM317T is an adjustable voltage regulator that requires a few external parts. See Figure 5.

If you cascade a current regulator and a voltage regulator, the current regulator acts as a very small value of resistance until all the current limit is reached. At values of current under the preset current limit, the voltage regulator simply operates normally. The combination of the two devices makes an excellent all-purpose power source offering the ultimate in flexibility and circuit protection. See Figure 3 for an example of how these two regulators may be cascaded.

Handling Increased Current

This circuit is a natural for the creative experimenter who needs a flexible power source for his experiments. The only thing to remember is that you cannot adjust the voltage to a value lower than the value of the regulator. This limitation, present in many commercially available supplies, is not a serious problem.

In fact, you won't have any serious problems with these regulators as long as you remember to properly heat-sink them. I have seen these units paralleled in an effort to increase current capacity, but I don't recommend it. If they have a small resistor in series with the output of each unit, you can parallel them, but voltage regulation worsens, even though power is divided more equally. A much better way to handle the problem of increased current is shown in Figure 4. Use a series pass transistor in conjunction with the three-terminal regulator.

Try a few experiments with these devices, and when you design them into your circuits, they will give your projects that little edge.

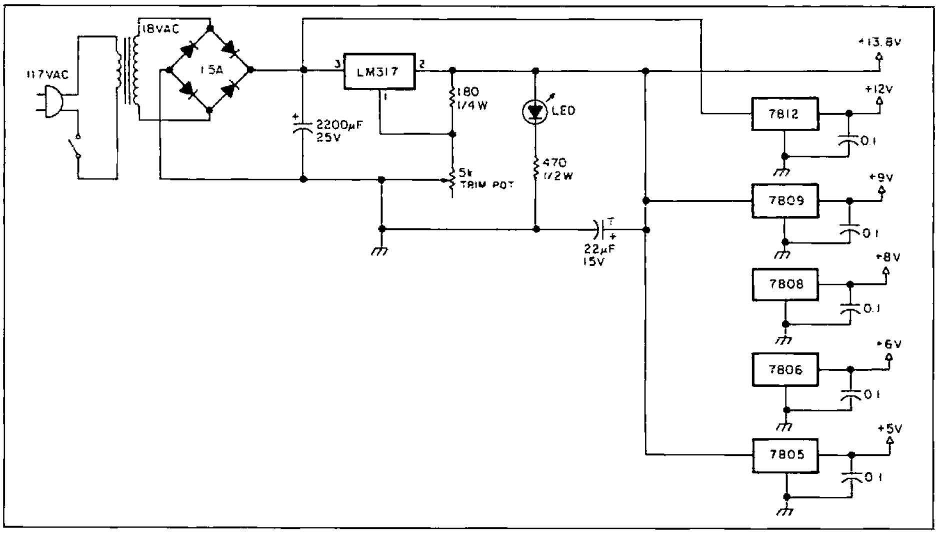
Great Ideas From Our Readers

Regulated Voltage Distribution Box

Not only do most hams have numerous gadgets which devour 9 volt batteries, they also have pocket radios, TV sets and table radios that use batteries. The most common voltages needed are: 4.5, 6, 7.5, 9 and 12 volts. Battery types needed include AAA, AA, C, D and 9 volt types. Batteries can be expensive, and often the size that you need is not on hand when you want it.

The gadget shown in Figure 1 solves this problem for all time. Any small transformer with a secondary of 18 to 24 volts AC at an ampere or more, a 1.5 ampere bridge, a few thousand microfarads of filter capacity, and an LM317 variable voltage regulator, forms the heart of this unit. The LM317 is set to provide +13.8 VDC output. Fixed regulators of 12, 9, 8, 6 and 5 volts provide the remaining output voltages. Output of the LM317 is bypassed by a 22 µF 15V tantalum capacitor, which will also bypass the inputs to all fixed regulators except the 7812, which is fed from the input of the LM317. All fixed regulators have their outputs bypassed by 0.01 µF monolithic capacitors. All outputs are self-protected and will deliver up to one ampere.



Although the LM317 and most fixed regulators are readily available from Radio Shack and most mail order sources, the 9 volt regulator (7809) is available only from *Short Circuits, P.O. Box 285, Barnegat NJ 08005.* They are sold four for $1. LM317T regulators from the same source cost 35¢ each. Type 7805, 7808 and 7812 regulators from Short Circuits are also four for $1. They have other fixed and variable regulators at similar prices, but do not carry the 7806 at this writing.

Use 5 volts for 4.5 volt equipment, and 8 volts for 7.5 volt gear. The slight voltage differential will not cause any harm. However, the 9 volt output will probably see the most service in the shack!

Finishing Up and Moving On

At last we're ready to wrap our ongoing topic up! So, let's finish our stage-by-stage troubleshooting now.

Mike amps: These amplify the mike's signal enough to drive the modulator. In FM rigs, they often will contain compressors, in order to keep the modulation from deviating outside the legal ±5 kHz bandwidth. (In SSB rigs, of course, the ALC feedback from the finals can prevent overmodulation.) FM amps may also incorporate lowpass filters, especially if the rig is to be phase-modulated (see below).

The usual problem with a mike amp is that it is dead altogether. Occasionally, one may work but be weak. These amps typically are ICs in walkies, but may be transistors in HF rigs. Troubleshoot as with any low-level amp, looking for a loss of signal at the output and working back until it appears. By the way, a common cause of mike amp failure in HF rigs is severe RF feedback. The voltages induced by the transmitter into the amp can be enough to blow the semiconductors. If you've had a feedback problem and then suddenly lose your audio, check the mike amp first! You could save hours of troubleshooting frustration later.

RF feedback itself is not a mike amp problem. It is usually caused by a poor station ground or by having the antenna too close to the rig. It may also occur when a mismatched or preamplified mike is used. If you're getting bad distortion or squealing on transmit, try running into a dummy load. What, you don't have one? No comment. But try reducing your output power as much as possible. If the trouble goes away, your mike amp is fine. (By the way, the RF power or drive control on many rigs, especially the tube-output kind, affects only CW and AM. Often, the only gain control in SSB is the mike gain pot! Try turning it down until the power output meter barely moves.)

Modulators: These are much like the mixers we explored in previous columns. They have two inputs and one output. One input, of course, is the audio to be modulated. The other is the carrier. In AM and SSB, the modulator is likely to be a ring of diodes, just like a balanced mixer. When the circuit is perfectly balanced, DSB is generated. (Subsequently, one sideband is clipped off by the sideband filter to make SSB.) For AM, the ring is deliberately unbalanced to allow the carrier through.

FM is another story. Modulation is accomplished by swinging the carrier's frequency back and forth in step with the audio signal. In one scheme, a carrier oscillator is varied directly, through the use of a varactor diode. This can result in very high-quality FM, but it is hard to do, because the oscillators are nearly always crystal-controlled, and therefore hard to swing enough for decent modulation. In synthesized rigs, which most are nowadays, it is possible to insert the audio into the VCO's control loop. As long as the PLL's loop filter is fairly slow, it will not notice the audio and will not try to correct for it. Thus, the VCO will wiggle back and forth in frequency. Voila, FM. In this case, the modulator may be no more than a transistor in a basic amplifier configuration.

Another popular FM scheme is phase modulation. It's especially common in rigs which multiply an oscillator's frequency several times to get to the actual operating frequency or to something high enough to heterodyne against another oscillator. Phase modulation is simple. You take a fixed oscillator and feed its output into a tank circuit comprised of a coil and capacitor in parallel. The cap, however, is a varactor diode. When audio is applied to the varactor, the changes in its capacitance will cause the tank circuit to shift the phase of the oscillator's signal back and forth. The only difference between phase and frequency shift is that the former occurs within one cycle. In other words, it is just smaller. When the signal is multiplied way up to the operating frequency, the shift is also multiplied, so it appears as if full frequency modulation has occurred. The drawback to this simple technique is that the modulation is nonlinear. For a given amplitude (level) of modulating audio, as its frequency rises, the rate of modulation (amount of frequency swing) also rises! Left alone, this would result in very tinny-sounding, ugly audio at the receiver. The cure is to insert a lowpass filter in the mike amp which reduces the amplitude of the audio as its frequency rises, thus exactly counterbalancing the modulator's rising effect. In practice, the two never exactly track, so phase modulation doesn't produce the quality of true FM. Nonetheless, it is a widely used technique because it is cheap and easy to do. Besides, the audio is good enough for communications use, which is never intended to be hi-fi anyway.

A CW modulator is basically a switch, usually made from a transistor. In order to make nice, clickless keying, though, it usually incorporates some capacitors and diodes, or other nonlinear time constants, so that it can turn on and off gently and at slightly different rates. That way, the carrier doesn't come on and off abruptly. A few milliseconds on each end is typical. If you can't key the rig, and the key or keyer is working and properly connected, the keying transistor is probably open. If the rig stays keyed all the time, it is probably shorted. If it keys and then locks up, check for RF feedback the same way as for a mike amp. Usually, that's the problem in this situation.

Some keying circuits can get surprisingly complex, with several transistors and perhaps some ICs. This is because some rigs require sequencing of various stages in order to avoid injuring their own circuits. For instance, the antenna may need to be disconnected from the receiver before the transmitter comes on. In any event, look for large shifts of voltage (a few volts or more) between the keyed and unkeyed states in each stage. If the shift disappears or becomes very small, you're near the trouble.

By the way, all of this applies only to all-solid-state rigs. If yours has tube driver and finals, the keying circuit can be quite different, and may involve dangerous high voltages.

Carrier oscillators: These are just local oscillators, exactly like the kind used in receivers. They may be crystal-controlled or be driven by the synthesizer. The distinguishing characteristic is that the frequency will be a few kHz different for USB than it is for LSB. The idea is to use the same SSB filter for both modes, and to approach it from either end of its passband. Oscillator crystals are a heck of a lot cheaper than SSB filters! If you suspect the oscillator is not working, try changing modes.

If it works on one sideband but not the other, suspect the defective one's crystal or its associated trimmer capacitor. If the oscillator is dead on both sidebands, the active element (transistor, FET, etc.) is the most likely culprit.

ALC circuits: These are much like receivers' AGC circuits, except that the input is a sample of the transmitter's RF output, and the circuit controls the power going into the finals. If your ALC meter doesn't work, and your transmitter puts out full power but overdrives, check here first. Most likely, you'll find an open transistor or RF sampling diode. If your transmitter is weak or close to dead, be sure it isn't being clamped off by a shorted ALC transistor before you spend big bucks for new finals.

RF power amps: This is tricky. Solid-state finals operate with high current, as much as 20 amps for a 100-watt rig. Circuit inductances can transform some of this into fairly high voltages (up to 200 or more volts) and that can be dangerous to work with, especially because the frequencies are RF. DON'T assume that, just because the radio runs on 12 volts, it is safe no matter where you stick your finger. You may be in for a nasty surprise.

The usual symptom of RF power amp trouble is very low or no output in transmit. People tend to blame the finals the way they used to blame the picture tube in a dead TV- it's dead so it must be the finals. Although replacing finals is very easy, it is also expensive. A pair of RF output transistors may cost you $80 or more. So, be absolutely sure you need them before you waste your money. Is RF getting to their inputs? Is the driver stage working? Often, the driver will go but the finals will be OK.

Or the finals will go and take the driver with them! Test all the transistors before you chuck them. By the way, low output, say 60 percent, is most likely not caused by bad finals. They are not like tubes—they don't weaken with age. I have seen leaky transistors reduce output, but it is rare and other symptoms, like severe distortion, should also be present.

OK, so the finals are indeed bad and you want to replace them. Before you do, ask yourself: What blew them? They rarely go by themselves. If you know why they went (shorted antenna coax, etc.), great. If not, check everything you can to be sure you won't blow the new ones. Nearly all solid-state rigs have some kind of SWR protection circuit, consisting of a reverse power detector near the transmitter output and a signal amplifier which limits the power going into the finals when the SWR goes above a preset limit. It's kind of like a receiver's AGC circuit, except that its input is from reverse power caused by high SWR. Check the detector diode and the amplifier transistors, especially if you suspect that high SWR killed your finals.

In HF rigs, changing the finals is easy. Buy a new pair, either from the radio's manufacturer or from a parts house. Always buy HF finals in pairs, even if one of yours looks OK. If their characteristics are not fairly well matched, they may not work well together, and may fail prematurely. Besides, if one failed, the other may be subtly damaged and getting ready to go. If it does, it may ruin your new one anyway. Install the new parts as you would any power transistors, and don't forget the thermal heat sink goo—it's an absolute must, except in cases where dry-type insulators are used. To be sure, just look at the originals. HF power amps are usually wideband, and don't require any trimmer adjustments. Most likely, you'll have to set the base bias. Consult the rig's service manual for the proper procedure. Failure to set the bias will probably result in poor operation and short-lived transistors.

In VHF and UHF rigs, the situation is quite different. First, there is usually just one final or a large power IC. Also, these amplifiers are tuned to operate over the band of interest, and replacement of the discrete variety requires adjusting various trimcaps and perhaps a few coils. The rig's service manual should detail the procedure, but you may find that it requires expensive equipment to do it right. The IC variety, however, is usually easy to change, and generally has few or no adjustments surrounding it.

Well, I think we've finally wrapped this mini-series up. Next month, something completely different! See you then. ■

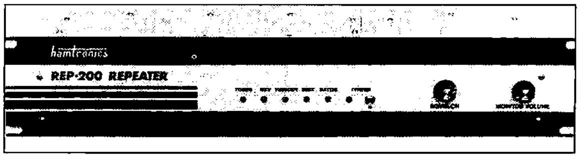
NEW PRODUCTS

Compiled by Hope Currier

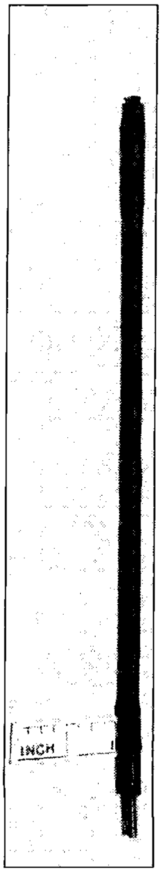


PRODUCT OF THE MONTH

HAMTRONICS, INC.
REP-200 Repeater

The microprocessor-controlled REP-200 Repeater is a successor to the popular REP-100 Repeater. It provides autopatch, two types of reverse autopatch, six types of courtesy beep, and a DTMF decoder/controller with over 50 functions. Until now, the REP-200 was available only wired and tested because of the complexity of building and testing the controller module. Now Hamtronics has made it available in kit form, with the COR-5 controller module prewired, programmed, and tested, for only $1095.

All of the repeaters are available for the 2 meter, 220 MHz, 440 MHz, and 902 MHz ham bands. (The 902 MHz version costs a little more.) For more information, call or write for a free 40-page catalog, and ask for the "supplement for repeater kits." Contact *Hamtronics, Inc., 65-F Moul Rd., Hilton NY 14468-9535; (716) 392-9430, FAX (716) 392-9420.* Or Circle Reader Service No. 201.



STATIC BUSTERS INC.

Static Busters Inc. has introduced their new Precipitation/Corona static device: the AS-1, a static discharge wick. The AS-1 will provide a path for electrons or static charge dissipation on towers and antennas of all types, and will reduce significantly or eliminate corona noise and precipitation static. During p-static or corona charging conditions the discharger can improve the noise level up to 20–30 dB or more, depending on the frequency.

The discharger (AS-1) is priced at $12.95 (plus $1 shipping & handling). Contact *Static Busters Inc., 3535 Sheperdsville Rd., Elizabethtown KY 42701; (502) 769-2244.* Or circle Reader Service No. 202.

STARTEK INTERNATIONAL INC.

The Model AP-90 Amplifier-Prescaler from Startek International Inc. can extend the range of any frequency counter capable of measuring to 16 MHz or higher, to 1600 MHz or 1.6 GHz. Two MMIC amplifier stages produce a superb sensitivity threshold of typically 1–5 mV RMS. The AP-90 also provides a 10-segment LED bar graph indicating the relative strength of the input signal. There are two overlapping ranges, 10 to 500 MHz/divide-by-10 and 300 to 1600 MHz/divide-by-100.

A special panel mount version, Model AP-90-H, is available as a custom plug-in accessory for the Hewlett-Packard 5245L/M, 5246L and 5248L/M counters. The AP-90-H has two-stage amplification of the input signal (rendering superb sensitivity over the entire operating range), a switch-selectable prescaler, divide-by-10 or divide-by-100, and an RF signal strength LED bar graph.

The Model AP-90 (including AC adaptor) is priced at $160; the AP-90-H is $180. When purchased from the factory or an authorized distributor, the AP-90-H has a one-year limited warranty to the original purchaser covering parts and labor if the unit should fail after proper usage.

Startek International also makes 1500 MHz hand-held frequency counters, prices starting at $100. Contact *Startek International Inc., 398 NE 38th St., Ft. Lauderdale FL 33334; (305) 561-2211, (800) 638-8050, FAX (305) 561-9133.* Or circle Reader Service No. 204.

JENSEN TOOLS INC.

The new 1991 *Master Catalog* from Jensen Tools is a complete source of tools, tool kits and test instruments for service and repair of electrical and electronic devices. This 232-page catalog features 11 pages of unique new tools and accessories for bench and field service, including new ergonomic tools, soldering/desoldering stations, a solderless terminal kit, circuit testers, probes, new products for static control, cleaning accessories, and more.

To order this free catalog, contact *Jensen Tools Inc., 7815 S. 46th St., Phoenix AZ 85044; (602) 968-6231, FAX (800) 366-9662.* Or circle Reader Service No. 203.

ELECTROSOFT

Electrosoft has introduced a CW keyboard program and interface kit for IBM-compatible computers having a serial port running on MS-DOS. The program and kit provide a convenient alternative to using a keyer if a computer is already in the ham shack. CW operators will be pleasantly surprised how the quality of code and ease of operation exceeds that of any keyer.

The program was designed using assembly language, resulting in an impressive, snappy response to each command. Operators will breeze through their first QSO because a HELP key displays all commands on the screen instantly any time help is needed. The speed may be adjusted from five to 100 words per minute, and the dot/dash ratio from 21% to 45%. Messages may be temporarily stored in any one of 10 200-character buffers, or may be permanently stored on disk. A REPEAT function will repeat CQs or beacon messages indefinitely. Contesters will enjoy the automatic serial number that can be incremented or decremented and inserted into a message. A CW sidetone may be turned off or on as needed. The interface kit is easy to build even for novices, and it usually requires about one hour to complete.

The program and interface kit is $50; the program alone is $25. For more information contact *Electrosoft, P.O. Box 1462, Loveland CO 80539.* Or circle Reader Service No. 205.

ZCo Corporation

73 gets lots of requests for information on Macintosh software for hams. ZCo Corporation is one source. Their catalog offers 11 programs for ham radio operators. This selection includes programs for theory and code training, mapping, logging, satellite tracking, and contesting.

For a copy of the catalog contact *ZCo Corporation, P.O. Box 3720, Nashua NH 03061; (603) 888-7200, FAX (603) 888-8452.* Or circle Reader Service No. 206.

INTERFLEX

Packet GOLD 1.2, a new software terminal program for the PK-88 and PK-232 controllers from InterFlex Systems, makes multiple connects easy. It uses a "next session" queuing system to take you to the next session with incoming text. With its continuous monitoring feature, you'll know what's happening on the channel at all times. Many functions provide additional support for multiple connects, including text search, cut/paste facility and connected station list.

Binary file transfers can be initiated at either the source or the receiving station. An integrated setup facility lets you customize the program to your needs. Put in "Quick-Connects" for point-and-shoot selection of frequently called stations. An integrated text editor allows you to edit text cut from any screen, or while editing a file.

This program is available for $60 (CA residents add 6.25%) from *InterFlex Systems Design Corporation, P.O. Box 6418, Laguna Niguel CA 92607-6418; (714) 496-6639.* Or circle Reader Service No. 207.

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

RTTY Loop XIV:7

Over the 14 years this column has run, the one single question I have received more often, time and time again, is a version of, "Did you cover this before, and if so, when?" So, from time to time, I have offered an index of past columns to help with locating topics covered. Several of you have suggested that I take the time to publish just this index, suitably updated, to help all of our readers. I herewith humbly comply.

This is a complete index to "RTTY Loop" from the beginning, organized by month and year. Now you know where to find the material that you're looking for. Getting copies of these articles will be up to you. I used to provide copies for a nominal fee, but the pressures of my job and family have cut into the time required for that. If you need reprints, contact *73 Amateur Radio Today*, WGE Center, Forest Road, Hancock NH 03449. Enclose a check for $3.00 for the first copy of an article and $1.50 for each additional copy.

Next month, we'll look at what some of you have been saying! As always, I look forward to your comments, suggestions, and criticism. Just pen a line to me at the above address, or e-mail it to me on CompuServe at 75036,2501, or on Delphi via MARCWA3AJR. Any way you send it, I look forward to reading your thoughts about "RTTY Loop"! 73

S. Georgia and the S. Sandwich Islands

In October we were very disappointed to learn that the DXpedition to South Georgia and the South Sandwich Islands had been postponed. Tony WA4JQS, organizer of the DXpedition, told me that the DXpedition had been postponed, not cancelled. With the Middle East crisis causing an increase in fuel prices, Tony explained, the shipping company had to put a hold on shipping traffic in the Antarctic area. The fuel expense alone for the DXpedition charter had increased by more than $40,000.

Equipment and supplies will be stored until the DXpedition becomes reality. All expenditures have been paid by the team members themselves, and all donations are safe in a bank account. Tony also noted that other possibilities are being investigated. The South Sandwich Islands remain on the inactive list, but there is at least one station currently active from South Georgia Island. Gordon VP8CDJ has been active since late last year, but he leans towards DX nets and does not operate CW. Gordon's QSL manager is GM4KLO.

Wanted: Adventurer, Sailor, CW Op

In June of 1991, Doug VE7NH intends to leave VE7 aboard his 30-foot sailboat for an island-hopping journey across the Pacific, stopping at some of the more rare DX spots. If permission is obtained, he'll operate from each. His list of DX stops includes Palmyra Island, Kingman Reef, Rotuma, Christmas Island, Mellish Reef, Willis Island, Norfolk Island, Kermadec Island, and Campbell Island.

Doug is looking for a sailing companion competent with CW who is willing to share costs and help sail the boat. The sailing companion need only participate in part of the trip. Contact Doug at the following address: Doug Brabner, 1429 Williams Ave., North Vancouver, BC V7L 4G1, Canada (or on 14025, 18071, 21025, 24900 or 28025 kHz). All inquiries will be answered.

Thailand

According to John K9EL who travels to Thailand several times each year, it is not true that any visiting ham can operate a RAST (Radio Society of Thailand) club station. If you are planning to visit Thailand, John suggests that you write to Sombat HS1BV at his *Callbook* address well before the visit. Prior arrangements must be made, and operating permission is not guaranteed. HF operation in Thailand is on a temporary basis, and is subject to change at any time.

Other active stations in Thailand include HSØAC (was HSØSM) at the Science Museum in Bangkok; HSØB, RAST club station in Bangkok; HSØAIT (was HSØA) located at a university about an hour's drive from Bangkok. QSLing to the HS bureau is not reliable. QSLs for Thai stations should be sent to the published QSL manager or as directed by the operator. Individual operators of club stations can often manage only their own QSOs. Confirmations of HSØAIT contacts is difficult at this time.

John has attempted a lot of 80 and 40 meter activity from Thailand, but he reports that the noise in Bangkok is just unbelievable. Commercial stations operate at will, and there is significant interference from nearby TV, radio and military transmitters. There is also significant interference from nearby countries where the amateur radio bands are not protected. John passes along his thanks to everyone who has sent contributions with their HSØE QSL requests. These donations help to improve the station equipment at HSØE.

QSL Notes

9M2AX, 9M8AX and 9M8XX. JA5DQH was the QSL manager for these stations, but he is currently active as HI8A and will be in the Dominican Republic for one to two years. Ross 9M2AX asks that all QSLs for these stations be sent to him: Ross E. Tanaka, F7, Menara Impian, TMN TAR 60000 Ampang, Kuala Lumpur, Malaysia.

SMØKCR is the QSL manager for LU2BC, 7S8AAA, SMØOIG/YN, SMØOIG/LU, HT3A, H71A, SMØMT and SKØUX has a new address: PO Box 1441, S-18314 Taby, Sweden.

CIØGI Grosse-Ile. The ARRL's DX Advisory Committee (DXAC) has voted not to recommend that Grosse-Ile become a separate DXCC country. The vote was unanimous. The ARRL Awards Committee makes the final decision about DXCC country matters and is expected to echo the no-vote. The island, located in the St. Lawrence River near Quebec, was activated during late July 1990 by a group of operators from Quebec. 73

World Class Hiding

Transmitter hiding can provide as many surprises as transmitter hunting. Most of the time the surprises add to the fun. Last month I presented construction plans for the Fox Commander, which remotely controls the audio and on/off timing of your hidden transmitter. The only things left to add on that topic are a few general precautions to help avoid some not-so-pleasant surprises.

Smart hidden transmitter operators take no chances—they **check out the setup well ahead of time and take back-up gear** if they have any. There is nothing worse than being out in the boonies and discovering five minutes before the hunt is to start that the gear won't work.

At least one day before the hunt, set up your remote-controlled hidden T system in your back yard and give it a thorough run-through to discover any incompatibility between the various pieces of gear. Does the third harmonic of the 2 meter hidden T fall close to the 70cm remote control frequency? If so, your remote control range may be very small. Check it.

What about interference from the high-power hidden transmitter to sensitive CMOS circuitry in the tone box? This problem can be particularly bad on 10 and 6 meter hunts, but it could happen on any band. The usual RFI suppression techniques (chokes and capacitors) will cure the problem, but it's vital to find out well before hunt time.

Is the supply current drain what you expected? Check to see what happens as your big 12-volt battery discharges down to less than 11 volts. Does everything keep running, with just a reduction in RF output power, or does some item of gear "lose its brains"?

Murphy Lurks

Even if you are convinced that you have found the perfect hiding place, one which will foil the hunters and "spread 'em out," you'll probably have nagging doubts. What if they all get exactly the same bearing, take the same route, and arrive at the same time? What if conditions change and they can't hear the signal at the start point? What if someone put up a new fence or gate and you can't get back to that great hiding spot you found last weekend? Murphy loves foxhunting because he can foul things up for hunters and hiders alike.

Two years ago, WA6OPS and I put on an 8 p.m. hunt that was sure to be an "all-nighter," even though we were only 11 miles from the start point. To get to the spot, you had to find a dirt-and-gravel path that went along a railroad track for about a mile and a half, then up over a hill and down into a canyon on a fire access road.

The only vehicle entrance to the railroad path was next to a bridge, with a steep drop-off that made the turnoff nearly impossible to see at night. Other roads led up to the railroad tracks, but they were closed with high construction fences.

Just 45 minutes after the start, a set of headlights topped the hill, and we were found, followed soon by the rest of the teams. Curses! The construction workers had opened up the fence in the intervening week since we discovered the spot. Moral: **Recheck the area of your site just before hunt time.**

Watch out for propagation changes. About a year ago, WA6TQY hid a 2 meter flea-powered rig on a hillside in Rancho Palos Verdes, carefully positioned to be shielded from the Diamond Bar starting point. Just as expected, the initial signal was very weak, and propagated by reflections from the mountains to the north of the start point. Many hunters took off toward the mountains, just as a bank of low clouds began to come in from the ocean.

As this marine layer blanketed the start point, the few teams remaining noticed a big change as they rotated their beams and quads. In addition to the weak signal from the mountains, there was now also a much stronger signal from the southwest. Those that followed the southwest signal went straight to Palos Verdes, where they found the fox.

It took the marine layer to propagate the signal over the intervening hills in a direct path. WA6TQY's skulduggery was the victim of a change in the weather, and the teams that spent a few extra minutes plotting their bearings got a lucky break.

Hunts to Remember

Everyone has his own idea of what constitutes the ultimate hunting challenge. To some, it's long distance. Any 2 meter hunt over 200 miles, such as the Los Angeles area hunts that have ended in Arizona or Nevada, surely must be world class.

To others, there has to be more than one transmitter to hunt. RDF enthusiasts from the Phoenix area brag how they can bag four, five, or more foxes in a single evening.

A combination of long distance and multiple T's certainly could be world class. Last September, AF6O and N6MI scattered four transmitters in the Mojave Desert. The first was 56 air miles north of the start point. Each successive fox was about 35 air miles farther east. The shortest road mileages between them were much greater, of course, and there were plenty of signalreflections from the

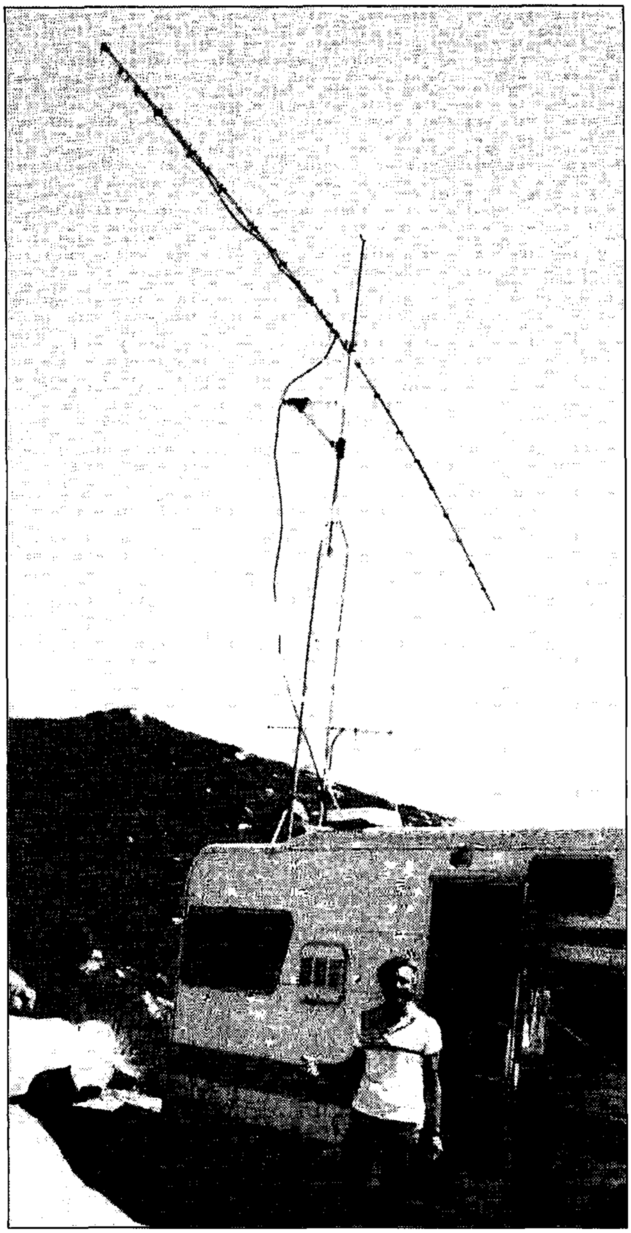

Photo A. Tom Wilson AJ6L can smile because his hard work in setting up this hidden station paid off in a successful T-hunt at the 1990 ARRL Southwest Division convention.

Photo B. Teresa Ashley N6UZH and her mother, Jo KB6NMK, are overjoyed moments after finishing "in the money" in a world class mobile hunt.

I CAN'T WAIT TO GET MY NEW RADIO --- I TOLD THEM I WANTED ALL THE BELLS AND WHISTLES ON IT

surrounding mountains.

Only four of the 10 starting teams found all four transmitters. Winners Deryl Crawford N6AIN and Tom Ritchie N6FBH put 383 miles on the odometer and took almost 16 hours to complete the hunt. The highest mileage among those who found all four was over 660 miles! You will know you have put on a great hunt when the hunters keep talking about it on the local repealer for days.

The annual ARRL Southwest Division convention almost always includes a world class transmitter hunt to close the festivities on Sunday afternoon, usually with some valuable prizes. The convention T-hunt committee has a tough job. The hunt must be a challenge to experienced hunters, but not intimidating to newcomers. It must not appear to give unfair advantage to locals, who have hunted frequently near the convention site.

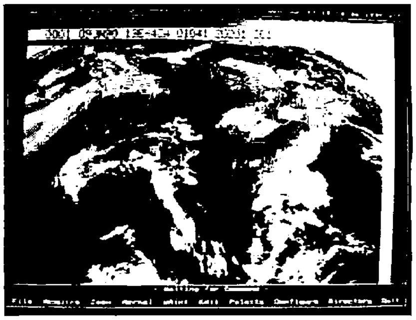
Tom Wilson AJ6L went to a lot of effort to put on the T-hunt for the 1990 Southwest Division gathering in San Diego last August. Tom hid at the end of a four-mile-long dead-end road down a creek emptying into San Vicente Lake. The end point overlooking the lake was well-shielded from the start point, but it was line-of-sight to the Silverwood and Mil Pedra Wildlife Sanctuaries and a nearby Indian reservation.

To make sure he splattered signal all over those places, and to be audible at the start, Tom needed a "killer" setup. He used a 20-element yagi on a crank-up tower, fed by hardline from a 500-watt amplifier using a pair of 4CX250 tubes (Photo A). Power for this setup came from a generator on the side of the embankment. Even with all this, it took a beam or quad to hear the signal at the beginning.

Eighteen cars, trucks, and vans competed for cash prizes in this event. Teams that did this hunt right never left pavement, bul those that went to the sanctuaries or reservation were in for a long, dusty afternoon of dirt-roading. The super-strong signals there made them think they were very close, even though Tom was actually over two miles across the lake by air, and over 20 miles by road.

Jerry Gastil K6DYD from San Diego drove the winning vehicle, assisted by N6WKT, N6WKS and WB6DTA. The mother-daughter team of Teresa Ashley N6UZH and Jo Ashley KB6NMK from the Escondido area hunt group came in second (Photo B). Time was the only factor in determining the winner.

Planning Is already under way to provide an unforgettable hunting challenge for the 1992 ARRL National Convention at the Marriott Hotel near Los Angeles International Airport. The Fullerton Radio Club is in charge of T-hunts for this convention, and welcomes your ideas. Send your thoughts to me and I'll forward them. Also, I would love to hear about your hiding experiences, whether world class or not. I'll share the best ones in this column. 73



Quorum introduces the first totally integrated system for the reception of weather satellite images directly on your personal computer. Selection of HF NAFAX, GOES WEFAX, GOESTAP, METEOSAT, NOAA and METEOR APT (including satellite downlink frequency selection) are made under complete program control from your PC keyboard.

The easy to learn and use Menu driven program allows you to capture, store, retrieve, view and print images with a few simple keystrokes. Images can be colorized from a palette of up to 262,000 colors when using a VGA display.

System configurations capable of NAFAX reception start at $399.00 while fully capable systems can be configured for $1500 to $2000.00, providing professional quality at low prices.

For complete information and a Demo Disk, call or write:

Quorum Communications, Inc., 1020 S. Main St. Suite A, Grapevine, TX 76051 (817) 488-4861. Or, download a demo from our Bulletin Board by calling (817) 421-0228 using 2400 baud, 8 data bits and No parity.

Receive Weather Satellite Images and Charts on your PC with Quorum's Totally Integrated and Affordable Weather Facsimile System

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Continued from page 4
ters to retrieve a dropped antenna . . . then running out of water on a desert island.

Then there was the morning I worked W7IMW/C7 in Tiensin, China, who was coming in S1 running 10 watts AM to a long wire on 20m. Wow! Or the night I worked all states on 75m. Or the weekend I worked 100 countries on 20m SSB. Or operating JY1 from the palace in Amman.

It was amateur radio that got me into the Navy as an electronic technician and paved the way for me to almost get killed a dozen times in a submarine. You sure learn about yourself when depth charges are dropping all around and you're not at all sure you're going to get out of this one.

Would an affair with a gorgeous Tech (a YL, thank you) count as a ham expenence? That's one chapter in my memoirs you won't want to miss! Heh. I wouldn't trade a top listing on the Honor Roll for that one.

So let's see what you can come up with. Who knows, if I get enough interesting stories I might be able to publish 'em all in a book. How'd you like to have your story in a book?

Yes, double-space it. We'll clean up the grammer and speling. Please don't use those torn spiral-bound notebook pages you usually send in, okay?

QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year subscription (or extension) to *73*. Entries not in envelopes cannot be accepted

High Tech Council

The New Hampshire High Tech Council, which I joined several years ago, is now interested in my project to get all New Hampshire schools to include an eight year course, grades 5–12, on the fundamentals of electronics, communications and computers. I suggested this some time ago, but it wasn't until the current economic downturn in New Hampshire that the timing seemed right.

The whole Boston and southern New Hampshire area bet far too heavily on minicomputers. It isn't as if I hadn't warned 'em that microcomputers would eventually clobber minis . . . and then mainframes. Well, they're doing it now and the result is that Data General, DEC, Prime and Wang are on the skids, with no real hope for long term survival. Alas, these huge employers are passing along their inability to cope with progress to the nearby communities.

I remember trying to convince the president of Centronics, in Hudson, New Hampshire, then the largest manufacturer of printers, that micros called for a whole new generation of printers. He scoffed. Now his plant is making pancake turners and the Japanese are making our printers.

Will we be able to convince the governor that a technically educated work force is the best answer for the future of New Hampshire? We're going to try.

The fallout for amateur radio will be, I estimate, at least 2,000 new amateurs a year, just from New Hampshire alone. We have about 20,000 youngsters in each grade, so if we can get this course into the schools, complete with ham, computer, science fair and other such clubs, I think we can get at least 10% of the kids sold on hamming. I'll let you know how we do with this.

It'll take several years for the project to produce a work force large enough to attract new high tech businesses to New Hampshire. In the interim I have a sneaky plan for a radio/computer project which could get the state back on even keel within a year or two.

If they do get my education project going, New Hampshire is going to be needing a technical university. I'd like to have RPI help develop this since I'm involved with the school. I talked with the president recently and he's game. This could be a perfect opportunity to start a new no tuition engineering university. Let's see, if we can start fifth graders now they'll be entering college in 1999. This could provide New Hampshire with technicians by 1999, engineers in 2002 and scientists in 2004.

ARRL Bashing?

Did you ever try to talk with a drug addict? If you have any friends who are alcoholics, you know that they protect themselves from reality by denial until the situation is beyond being ridiculous. This is the way drugs work, including cigarettes, cocaine, crack, gambling, and so on. Denial.

My recent prescription for saving amateur radio via getting the ARRL to do what needs to be done has resulted in a few ARRL-holics accusing me of bashing the League. Let's put this into perspective.

I'm not "against" the ARRL, any more than a doctor is against a person when that doctor diagnoses a case of cancer and recommends an operation. Diagnosis isn't criticism. As a doctor of entrepreneurial science, I'm in a unique position to diagnose the situation and prescribe what needs to be changed for the health of the League.

So cut out the "bashing" baloney, notice that you're into denial, and let's start curing the patient instead of attacking the messenger. 73

Notes from FN42

HAPPY NEW YEAR! As I am sitting in the Dungeon (my shack) I reflect on the past year and all the fun things that I have done, plus all the wonderful things that hams around the world have been doing or are planning to do. I certainly wish that I could attend many of the conferences, meetings, or just generally good times that are happening, but alas, I cannot. I sometimes wonder how Wayne does it, but he is a natural go-getter and no moss grows under his feet.

I am very happy to report that Wayne has been recruiting Hambassadors for the column. Harris Abdullah 9M6HF is the latest, and you will see his first installment in this month's column. Thank you, Wayne, from all of us.

What will the new year bring? I hope it brings complete world peace, better understanding between countries and individuals, and prosperity for all. I do know that the staff at 73 Magazine *will be striving to continue the excellence that 73 is known for, and that this column will bring you all the news from around the world.—Arnie N1BAC*

Roundup

Spratly DXpedition. *[This press release ended up in my box from an unknown source.]* The recent Spratly DXpedition was a major success, despite various problems. Romeo Stepanenko 3W3RR and a team of Soviet operators contacted over 43,000 stations worldwide in April–May of 1990. Many people and organizations banded together to donate funds for that trip and made it possible. However, there are still many amateurs who would like a shot at Spratly for a new one, phone or CW.

Romeo, well-known to the Vietnamese, can obtain a passage to the Islands on very favorable terms. His new expedition will take him *[or has taken him]* and one Vietnamese assistant to Spratly island for a week-long operation.

Donations will be greatly appreciated for this effort. They can be submitted to: Ed Kritsky NT2X, Box 300715, Brooklyn NY 11230, USA. If the total amount needed, $5,000, cannot be raised, all contributions will be returned to their donors.

Switzerland *From a press release of the International Telecommunication Union (ITU).* Taking advantage of new technologies available in the field of information retrieval, the ITU is now publishing the International Frequency List (IFL) on CD-ROM (compact disc—read only memory). The computer readable edition is an improved version of the existing IFL on microfiches.

From the first edition of the "Berne List" published in 1928, to the latest edition of the IFL produced on paper, the number of frequencies increased from 1,700 to about 1,100,000, representing an increase in the number of pages from 24 to over 6,000! This led the Union to cease the publication of the list on paper and to adopt microfiches as from 1985. The CD-ROM list is yet another step to make this publication more flexible and useful than ever.

The CD is used with the CD-Answer information retrieval software delivered on the accompanying diskette. You can access information by frequency, country code of station location, notifying administration, class of station, station name, geographical coordinates, or geographical area and region code. It also enables users to process any extracted subset of the database in local application systems.

Photo A. Famous Taiwanese ham BV2A/B, Tim Chen (in the middle), visited the Tokyo International Amateur Radio Association (TIARA) booth at the annual Harumi Ham Fair last August. With Tim, left to right, are TIARA Technical Advisor Ed Coan 7J1AAE; member VU2ST, Ali; President Frank Striegl 7J1AAL; and member Motoi Kawatsu JK1PNY.

Photo B. Father Marshall Moran (in the middle), world famous as 9N1MM, receives 10 Novice study guides from TIARA for his students in Nepal, where he has been promoting amateur radio for 35 years. Father Moran was in Tokyo last September at the invitation of the Japan UNICEF Ham Club. Also present (left to right) are Andy Clark 7J1AAD, TIARA President Frank Striegl 7J1AAL presenting Father Moran with Tune in the World, *and Brother Albert Heinrich 7J1ACI.*

MALAYSIA

Harris Abdullah 9M6HF
P.O. Box 13329
88837 Kota Kinabalu
Sabah Malaysia

Greetings from Malaysia. Amateur radio is alive and growing in Malaysia. Malaysian Amateur Radio Transmitters Society (MARTS) has been doing a tremendous job in promoting the hobby through participation in social and sports activities.

In 9M8-land, interest in amateur radio was generated when Special Event Station 9M8STA went on the air in August 1989 for three days. The first amateur satellite communication from Eastern Malaysia was made through this station. And this year, 9M8 hosted the Annual SEANET Convention held in Kuching from November 10–12.

Sabah, 9M6, has 29 licensed hams, but only eight can be heard on the HF bands on a regular basis. 2 meters is also active, and a repeater, 9M6RGK, has been installed at an altitude of 9,000 feet on Mount Kinabalu. At this height, the repeater's coverage extends as far as the northern part of V85-land, Brunei. The repeater was home-brewed by 9M6MA. It is easily accessed from Kota Kinabalu, about 40 miles away. The Sabah Amateur Radio Society represents the interest of the local ham population in 9M6.

There are many SWLs in Malaysia. Most have been able to pass the RAE Part I Examination (Theory and Regulations) but the main stumbling block is Part II, CW. Part I consists of multiple choice questions on theory, practice of radio communications, and the local regulations covering the hobby. Part II tests the ability of the candidate to receive and send messages in Morse code at 12 wpm.

Presently, there is only one class of license available. However, plans are underway to amend the regulation to provide for Class B (VHF only). This requires passing Part I of the exam only. Another change that may come soon is the lowering of the minimum age requirement from 18 to 16. The examinations are conducted twice a year in June and December by the Department of Telecommunications. Amateur radio licenses are valid for a year, and the fee is M$20.00 per year for fixed/mobile/portable operations.

Malaysia does not have any reciprocal licensing agreement with any other country at the moment. Hams who intend to operate while visiting the country need to submit an application form at least two months ahead of the arrival date, to allow time for processing. The issuance of a temporary license will be at the discretion of the licensing authority.

If you intend to operate from 9M2, write to MARTS, P.O. Box 10777, 50724 Kuala Lumpur, Malaysia for assistance. For 9M8 and 9M6, write: 9M8FH, Festus Havelock, P.O. Box 203, 93702 Kuching Sarawak, Malaysia, and 9M6HF (myself, address above).

The main problem hams face in Malaysia is the high customs duty levied on amateur radio equipment. MARTS is constantly working to have this reduced or removed for the sake of the amateur radio community. Importing an HF rig is costly, almost double the purchase price of the equipment. This is why there are not many licensed hams active on the HF bands.

SPAIN

Woodson Gannaway N5KVB/EA
Apartado 11
35450 Santa Maria de Guia
(Las Palmas de G.C.)
Islas Canarias, Espana

Hello again from the Canary Islands. I am very happy to provide a translation of an article printed in a local newspaper about the hams in the province of Las Palmas (the islands of Grand Canary, Lanzarote, and Fuertaventura). Alfonso Hernandez, President of the Union de Radioaficianados de Espana (URE), provides the narrative for the reporter.

In the province of Las Palmas (the islands of Grand Canary, Lanzarote and Fuertaventura) there are approximately 800 ham radio operators, 650 of them on Grand Canary. On Lanzarote there are two local branches (in Teguise and Arrecife), and another on Fuertaventura. In all, there are 1,730 hams in the Canary Islands.

The URE was created before the Spanish Civil War, and then it disappeared. It began anew 27 years later, in 1963. Before the movement, there were only a few licenses, but they were easy to obtain. Quite different from the situation we saw later; although thanks to our "dean," Jose Callero, people kept up their interest, and began transmitting again when it was allowed.

In 1980 things began to settle down, and in those times, Las Palmas province had about 80 hams. New rules and tests were put into practice in 1983. In Las Palmas the URE chapter was changed to the form it has today, with its own jurisdiction, instead of being a branch of the Madrid office.

There is no average Canary ham. The strongest interest comes from young adults between 20 and 40 years old. There are older people too, but they have more problems in passing the tests.

Equipment normally costs around 500,000 ptas ($5,000), including installation of a multiband antenna. But at any rate, you don't need a rig to be a ham. You can become a club member and use the club callsign. Membership dues in Las Palmas are $60 a year.

In Las Palmas there is a packet repeater and two 2-meter repeaters. There is a 2 meter repeater on both Lanzarote and Fuertaventura.

Our ham services are largely emergency services, such as requests for medicine. We are constantly asked to search for medicine in all parts of the world; above all, this is a humanitarian service and not limited to our country's borders. When someone asks you to get medicine and you go to the trouble to get it and send it, and then they tell you that this has helped save a life, this makes you very happy. I think that it is things like this that a ham is proudest of.

To become a ham one must pass a series of tests that cover four areas: operating the equipment, basic electronics, pertinent Spanish law, and Morse code. The club offers classes to prospective hams. After passing these tests the ham receives a callsign prefix of "EC." He stays at this level for a minimum of 6 months while making 75 contacts (25 national and 50 international). Then he can test for "EA," the highest license category. If he wants to enter the "EB" class he has only to pass a written exam (no code). This class allows limited use of the VHF bands.

Until next time, 73 from the Islas Canarias.

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. You may also upload a listing as E-mail to Sysop to the 73 BBS, (603) 525-4438, 8 data bits, 0 parity, 1 stop bit. Thank you for your cooperation.

Wanted: a Morse code trainer program for the Apple IIe to help boost a new Novice to 13 and 20 wpm. *T. Francis, Rt. 2 Box 336, Leonard TX 75452.*

I am looking for any info on KLM Electronics Echo II, 144 MHz transceiver. I will copy or pay for copy and postage. Contact *Rick Bogdan KA1UDX, 136 Samoset Ave., Hull MA 02045 or KA1UDX @ NS1N.MA.USA.NA.*

Elmer wanted! I have an FT-707, and study code on computer. I have books, but learn best by listening and doing. Please respond. Thank you. *James E. Fiuren, PO Box 2394, White City OR 97503. (503) 826-5190.*

I cannot locate a company called the Dentron Radio Corp., and I need circuit diagrams or operating manuals for the ant. tuner Dentron Jr. Monitor, Serial #6207. I will pay any cost involved. *Ray Terrill ZL1AAR, 3F Faith Bullock Pl., New Lynn, Auckland 1207, New Zealand.*

Can anyone tell me anything about a Zenith PM-1 cable system used for scrambling? Also, I'm looking for a copy of a book called *The Ten Meter FM Handbook*, by Bob Heil. It has been out of print for about 5 years. I will pay copying charges for this book. *Bret Singer N3IHM, PO Box 1015, East Stroudsburg PA 18301.*

I am interested in SSTV, but have no idea what kind of equipment I need, where to get it, or how much to spend. Any help I could get would be appreciated. I operate a TS-820 for HF (barefoot), and have a 3-element tribander. *Kevin Webster N1EPU, 1564 Byam Rd., Cheshire CT 06410.*

Needed: Info on full break-in CW. Does the B&W tube type break-in device still exist or does anyone have anything simpler to use with separate transmitter and receiver? *Bill Pierce, 142 South Keystone Ave., Sayre PA 18840.*

I need the manuals (including schematics) for Lafayette Signal Generator TE-20. *Meyer Minchen AG5G, 4635 SW FWY, Houston TX 77027. (713) 622-6161.*

I'm looking for information about parts or service for a Wilson WR-500 antenna rotator. Thank you. *Sam M. Barrett WA5RPP, PO Box 141, Presque Isle ME 04769.*

W1BHD-ATV Pioneer

While visiting the Boston area, I decided to drop by and visit Mel Dunbrack W1BHD, also known as the "Grandfather of ATV." At 84½ years of age, he is still active on ATV in the Malden, Massachusetts, area. Mel built his first ATV station in 1948 and was one of the first ATVers on the air in the world. One of the first known ATV demonstrations (non-mechanical) was an eight-mile contact between W2USA at the New York World's Fair and W2DKJ/2 at the New York Daily News Building on September 27, 1940 (see *QST*, November 1940). This demo inspired Mel to construct his own station. In the '40s, things such as TV sets, and particularly TV cameras, were a little hard to come by (at ANY price!). Mel set out to homebrew his very own TV camera and converted a RCA oscilloscope to operate as a TV receiver!

From Spark Gap to Video

Mel started out in amateur radio with a spark gap transmitter he constructed in 1917. His interest in ATV was first sparked during the '20s when he saw the ads for the Jensen mechanical TV system (anyone still have one of these?). He worked in the electronics field starting out at AMRAD and eventually working at James Millen Company. If you've ever owned one of Millen's grid dip meters, Mel probably had a hand in building and testing it!

During 1948, three TV stations started up in the Boston area. WBZ-TV started broadcasting on June 9, 1948, WNAC-TV came up on June 21, 1948, and by November 20, 1948, W1BHD-TV was on the air! Mel wrote the FCC about identifying his TV signals. He received permission to add the "-TV" suffix to his call.

Photo A. Mel Dunbrack W1BHD with his omni-horizontal portable ATV antenna.

Photo C. From Spark to Video. The W1BHD 1948 vintage TV camera can be seen in the background.

Soon Mel had a following of several local hams watching his test patterns and live demos. If you think it's tough to stir up ATV activity in the '90s, just think of the hard road that Mel had to follow in the late '40s! Mel's eventual goal was to stir up a *riot* of ATV activity. To help achieve his goal, he started up the first ATV newsletter in 1951, called the "American Amateur Television Associates." In his first few months he had nearly 30 members (see the list).

After years of stirring up new ATV activity, he was instrumental in helping Tony K1VTE get the Malden ATV repeater up and running in the mid-'70s. He also had one of the first 2 meter FM repeaters operational in New England (WR1AAA—the "Skunk Hollow" machine).

Mel is an active member of the ECAT group (East Coast Amateur Television, Inc.). Although he is blocked by a hill from the current repeater site in N. Andover, Massachusetts, he still enjoys operating simplex ATV from Malden. Give him a call on the 145.29 repeater and help him start another ATV riot!

Backpack ATV

While at this year's Boxborough, Massachusetts, hamfest, I was treated to quite a variety of portable ATV activity. The ECAT group (East Coast Amateur Television, Inc.) had an impressive booth which received the transmissions from several backpack ATV stations scattered about the hamfest grounds. Seen hoofing it were Jerry N1FFX (see Photo E), Bob WA1WVJ, W1ELX, Lynn W1NRE and at least one or two others. The ECAT group had even arranged for a tethered blimp ATV station, but high winds and rain put an end to those plans.

If you're planning a trip through the Boston area, look for the ECAT group on the 145.29 (−600) repeater in N. Andover. The KA1AFE ATV repeater is located at the same site as the 2 meter machine on top of Boston Hill north of the greater Boston area. The input is on 434.00 MHz or 911.25 MHz and the output is on 421.25 MHz (both vertically polarized). Activity nights are on Wednesdays and Sundays around 8 p.m. 73

SPECIAL EVENTS

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the March issue, we should receive it by December 31. Please provide a clear, concise summary of the essential details about your Special Event. If your announcement arrives here too late to be included in the magazine, it will be entered in the /HAMFESTS SIG on our BBS, (603) 525-4438. 8,0,1.

DEC 30

SOUTH BEND, IN A Hamfest Swap & Shop will be held at the Century Center by the Repeater Valley Hamfest Committee. Tables: $5/5' round; $15/8' x 2.5' rectangular; $20/8' wall locations. Talk-in on 6.52, 99-39, 69-09, 34-94, 145.29. Contact *Wayne Werts K9IXU, 1889 Riverside Drive, South Bend IN 46616. (219) 233-5307.*

JAN 12

WESTBORO, MA The MMRA Flea Market, sponsored by the Minuteman Repeater Assoc., Inc., will be held at the Westboro Senior High School from 9:30 AM–2 PM. Admission is $2, or $1 after 1 PM. 6' x 6' vendor spaces $5 in advance, $10 at the door; with table & chair—$10 in advance, $15 at the door. Floor space with table and chair will be guaranteed only when paid for in advance. Vendor space requests should be sent by Jan. 1, 1991, to: *1991 MMRA Flea Market, PO Box 2282, Lexington MA 02173.* Talk-in: 449.925, 223.94, and 146.61 MHz. Contact *Andy Morrison N1BHI at (508) 481-3878* or *Ralph McNall WB2DCL at (508) 366-2404.*

JAN 19

MONTEREY, CA Winterfest 91 Demonstration and Flea Market will be sponsored by the Naval Postgraduate School ARC at The Monterey Fairgrounds, Salinas Room, from 8 AM–3 PM. Admission is free. For info, contact *Pat at (408) 649-4444 (days)* or *Doug at (408) 663-6117 (evenings).*

JAN 20

YONKERS, NY The Metro 70cm Network will sponsor an Electronics Fair/Giant Flea Market at the Lincoln High School from 9 AM–3 PM, rain or shine. Free parking. Admission $4. VE Exams. Tables: $15 for the first and $10 for each additional, $1.80 per foot. Pre-registration deadline is Jan. 10, 1991. For tables at the door: $20 all tables, $2.50 per foot. Contact: *Otto Supliski WB2SLQ, 53 Hayward St., Yonkers NY 10704. (914) 969-1053.*

JAN 26

GALLATIN, TN The 300 Repeater Ham Festival will be at the Gallatin National Guard Armory on Highway 25 East of Gallatin. Setup begins at 6 AM. Open to the public from 7 AM–2 PM. Walk-in testing. Tables are 1/$5, additional $2.50 each. Bring extension cords. Talk-in on 147.84/.24 from 5:30 AM. Contact *Bill Ferrell N4SSB, 1120 Douglas Bend Rd., Gallatin TN 37066. (615) 452-3962.*

CRYSTAL RIVER, FL The 11th annual Citrus County Hamfest, sponsored by the Sky High ARC, will be held in the National Guard Armory on Seven Rivers Dr., starting at 9 AM. Admission $4 until Dec. 20, and $5 thereafter. XYL's free with OM. Free parking. Vendor set-up from 3–5 PM Fri. and 7–9 AM Sat. 120V AC available at no charge. Users must provide plugs, cords and tape for attachment to floor where cords cross aisles. All exhibitors and helpers must purchase admission tickets. Parking for self contained RV's. Outdoor fleamarket spaces $5. Indoor tables $8 each. All tables are 30" x 8'. Chairs provided. Make checks payable to *Sky High ARC* and mail to: *SHARC Hamfest, 9 S. Davis St., Beverly Hills FL 32655.* Send SASE for mail return or pick up tickets at the door.

ARDEN HILLS, MN Those interested in microwave operations are invited to attend a meeting at the Satellite City radio store at 10 AM. Free admission. Contact *Jerry Jensen (612) 888-6187.*

JAN 27

VILLA PARK, IL The Wheaton Community Radio Amateurs will hold their 24th Mid-Winter Hamfest from 8 AM–3 PM at the Odeum Exposition Center. Handicap accessible. Tickets $5 in advance with triple prize stubs, $6 at the door. All Flea Market tables reserved. Call *(708) 231-2428.* Talk-in on 145.39/.79, 224.14/2.54, 444.475/9.475. For commercial space, call *(708) 629-8889* or *FAX (708) 629-7098.*

COLUMBIA, PA The Columbia Area ARC will sponsor a Hamfest at the Columbia Markethouse from 8 AM–3 PM. Set-up at 6:30 AM. Admission $3. Tables $5. Free parking. VE Exams. Talk-in on 146.715/.115. Contact *Hamfest Committee, Columbia Area ARC, PO Box 574, Columbia PA 17512. (717) 684-5603.*

FEB 2

ST. CATHARINES, ONT. The Niagara Peninsula ARC Inc. will hold its 13th Annual Big Event Ham-fest/Dinner-dance at the C.A.W. Hall. Admission $3, tables $12 commercial and $5 non-commercial. Talk-in on 147.24/.84. For info please write *N.P.A.R.C. Inc., PO Box 692, St. Catharines, Ontario L2R 6Y3, Canada. (416) 562-4891.* Dinner-dance tickets available only in advance.

SPECIAL EVENT STATIONS

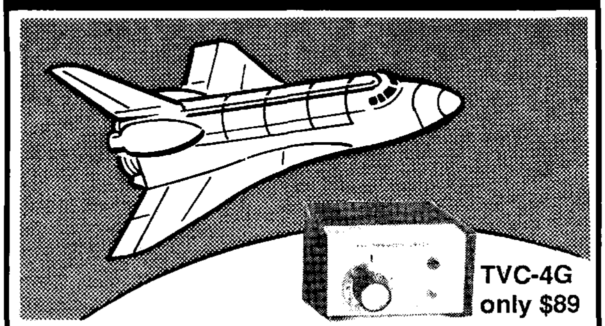
JAN 5-6, 12-13

RIO de JANEIRO, BRAZIL The Hunting Lions in the Air Contest, is sponsored by Lions Clubs International and coordinated by the Rio de Janeiro Arpoador Lions Club (Brazil). The CW portion of the contest will be held from 1200 GMT Jan. 5–1200 GMT Jan. 6. The Phone portion of the contest will be from 1200 GMT Jan. 12–1200 GMT Jan. 13. The contest commemorates the birthday of Melvin Jones, founder of Lionism. Its main objective is to create and foster a spirit of international understanding and cooperation among Lions and ham radio operators through worldwide communications. Bands permitted are 80, 40, 20, 15 and 10 meters, Phone and CW. For Phone: Calling: CQ...Hunting Lions in the Air, followed by callsign; Exchange: RST report, prefix and a sequential QSO number. An operator who is a member of a Lions, Lioness or Leo club shall indicate the word "Lion" and the name of the club. If possible, identify the district. The Rio de Janeiro Arpoador Lions Club members and the Melvin Jones Memorial Radio Club members will add the words "Arpoador" and "Melvin," respectively. For CW: Calling: CQ...Test Lions, followed by callsign; Exchange: RST report, prefix and a sequential QSO number. An operator who is a member of a Lions, Lioness or Leo club must indicate the letter "L": The Rio de Janeiro Arpoador Lions Club members and the Melvin Jones Memorial Radio Club members will add the letters "LA" and "LM," respectively. Make one log for each mode (CW and Phone). Clearly indicate the category (single operator or clubs and associations with multiple operators). Enter callsign, the band, the report and sequential number of QSO—both received and sent. QSO's in the different bands but in the same mode should be indicated in the same log. Logs must be mailed by Feb. 15, 1991, via airmail, to: *Contest Committee of Rio de Janeiro Arpoador Lions Club, PO Box 2155, Rio de Janeiro 20011, RJ., Brazil, South America.* Also, write to this same address for info about points and awards.

JAN 15-21

DULUTH, MN Duluth area hams will operate KB0DAV (Dogs After Victory), to commemorate the Eighth annual John Beargrease Sled Dog Marathon. Beargrease Amateur Radio Coalition (B.A.R.C.) provides a safety net for the health and welfare of the mushers and dogs during the 500 mile wilderness race. Operations will be on-going throughout the race, SSB and CW 10 through 80. For QSL send QSL and SASE to *BARC, PO Box 500, Duluth MN 55801.*

AMATEUR TELEVISION



SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. If it is being done in your area on 70 CM, all you need is one of our TVC-4G ATV 420-450 MHz downconveters, add any TV set to ch 3 and 70 CM antenna. Others may be retransmitting weather radar during significant storms. Once you get bitten by the ATV bug - and you will after seeing your first picture - show your shack with the TX70-1A companion ATV transmitter for only $279. It enables you to send back video from your camcorder, VCR or TV camera. ATV repeaters are springing up all over - check page 411 in the 90-91 ARRL Repeater Directory. Call for a copy of our complete 70, 33 & 23 CM ATV catalog.

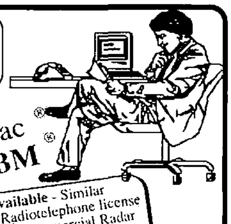
QSO Tutor

Study Aid for the Amateur Radio Exams



All you need to join the ranks of Amateur radio operators.* Obtain your Novice license or upgrade to a higher class the easy way on your personal computer with *QSO Tutor.*

Mac ®
IBM ®

Program Features:

- Runs on IBM Personal Computers and compatibles with minimum 256K RAM or Macintoshes with minimum 512 K.
- Programs are available for Novice, Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radio Telephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pool, selected areas, or additional questions automatically selected by the program from your weakest areas.
- Includes full screen graphics, explanations on appropriate questions and a pop up calculator on the IBM version.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or written on Epson/IBM or Macintosh graphics printers.

Now Available - Similar Commercial Radiotelephone license Tutor. $39.95. Commercial Radar endorsement $29.95.

"The most advanced program I've tried ... Graphics are extraordinary ... This program should be your first consideration..."
Gordon West WB6NOA, Worldradio Nov. '89

"Do I recommend the QSO Tutor? Heartily, yes! It really motivated me and it's a great way to test my progress. The learning is a natural by-product of the fun I am having."
Jim Bail KA1TGA, 73 Magazine Review Jan '90

"Thanks to your study program I was able to handle the examination confidently and passed with flying colors. If the Extra Class program is as helpful as the Advanced Class was, I look forward to working with it." **WA0NDF**

"Using QSO Tutor made studying for the exam enjoyable and interesting. thanks to your program I passed the technician test with a perfect score."
N3GME

"I easily passed my Advanced Class test on the first try thanks to your great software!!
WA3WOM

Thanks for thinking of us hams. Your program has eliminated the worry of the Theory part of the test for me." **KA3RHW**

$29.95 per class

PA residents add 6%. Price includes shipping. Add $2 each for 3 1/2" IBM Disks.

IBM Public Domain disk also available with excellent morse code tutor as well as a contest logger, propagation predictors, beam plotter and others. Cost is $3 to cover materials and handling, $2 if shipped with QSO TUTOR.

Gunn and IMPATT Devices

What is the difference between a diode and a Gunn diode? Why does an IMPATT (impact avalanche and transit time) diode check out like a diode, and a Gunn diode fail this test? This month we'll explore the internal characteristics of microwave diode oscillators, which will help you determine whether a device is still alive or a dud.

Most devices picked up at swap meets are in the realm of a trust relationship, as detailed testing isn't possible. But most cavities that appear from time to time at flea markets can be tested with simple equipment to help you determine the status and type of microwave device.

I have experimented with most of the microwave diodes available, and I try to pass on what I have learned in the process. The first rule is to look in the technical book section (621 division) of your public libraries. Using this privilege can save you lots of bucks. If you can't locate material there, you might want to check the nearest college library. I find myself continually looking for new material covering old ground. It helps explain what is going on, as it's simple when you can visualize the different devices.

The Basic Diode

The basic diode has one junction, a positive (P) and a negative (N) block of silicon. When you connect an ohmmeter across the diode (positive lead of ohmmeter to positive terminal [anode] of the diode, and negative lead to the negative terminal [cathode] of the diode), current will flow. The current is controlled by the voltage of the ohmmeter's battery and the meter/diode resistance. Some meters are better used on the times 10 scale, since the times 1 scale can supply more current, and could damage devices like detector diodes. See Figure 1 for the basic test circuit.

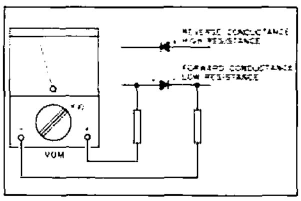

Figure 1. The basic diode test circuit.

When using the ohmmeter for testing a device, first note the reading in the forward biased direction, then reverse the meter leads. The reverse reading should be 20 times greater, or more, for a good diode. Some devices will indicate open or infinity on your ohmmeter. This is OK. The point is that the diode in conduction measures low resistance, and in reversed polarity, is very high or open to the meter circuit. This is a simple test for rectifiers, zeners (below reverse breakdown voltage), and similar devices. These devices can handle larger currents, such as the high currents the meter might apply to them.

Applying this type of test, you can destroy some microwave devices, since some junctions of transistors, especially FETs, can be punctured by the meter's voltage. If the device is a bi-polar transistor, you can get away with it, but be careful of the voltage and the amount of current that the meter supplies. Check the battery in your meter and its polarity in reference to the meter leads. It helps when the positive battery voltage in the ohmmeter test is on the red or positive side.

Don't use the highest meter scale. Stay on the times 10 scale to limit current. I use a Triplett model 630, 20k ohms per volt, to do my tests. On the X-10 ohms scale it uses a 1.5 volt battery for tests. This is my swap meet and general purpose meter.

IMPATTs and Gunn Oscillators

Let's get into the innards of the microwave devices and find out what makes IMPATT and Gunn diodes different. The basic difference lies in the materials used to construct each device. Both devices produce microwave oscillations at various power levels and are quite compact compared to the older tube systems they replaced.

The Gunn device is constructed of a triple layer of "N" type semiconductor, actually a very thin wafer a few microns thick (the actual Gunn surface). This active Gunn element is sandwiched between two "N" blocks of material allowing a bonding surface to the very thin Gunn material. As such, the Gunn device does *not* have a diode junction. Because the Gunn's three-piece construction consists of only one type of material, "N" type, it doesn't test like a normal diode. Why it is called a diode (implying two elements, anode and cathode) eludes me.

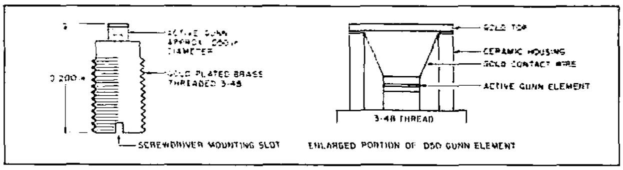

Figure 2. Gunn diode construction. Frequency of diode determined by thickness of Gunn diode wafer. A thick wafer indicates 6 GHz, a thin wafer indicates 10 GHz.

Testing a Gunn device with the ohmmeter will show a dead short of about 2 to 3 ohms in either direction. The problem is that this may be a good Gunn device! Reversing the meter leads won't help; you'll get the same reading. Remember I said the device has no diode junction and is constructed from a single (triple-layer sandwich) block of "N" type semiconductor material. What is required is some means of observing microwave operation in a cavity to check for microwave operation. See Figure 2 for the Gunn's structure. (Note: The Gunn device can operate using strip lines, but efficiency is very low, about 2%.)

The Gunn device is a bulk semiconductor (solid) that causes the DC electron flow through the material to bunch in clumps of electrons. These clumps or bundles of electrons represent pulses of current in a resonant cavity, and comprise the microwave period, or resonant oscillations. Cavity operation of Gunn diodes is the most efficient method used today to produce high power units.

I visualize this bunching effect by picturing ten thousand BBs rolling down a plank. Due to collisions and other factors, some electrons (BBs) slow down, while others speed up. The result is that they vary in speed, and bunch up at a rate that is the resonant frequency of the cavity. This output power obtained at microwave can vary from a few mW to over half a watt.

Gunn devices are voltage-fed, meaning they can have all the current they want to draw from the supply at a particular voltage. Please note that Gunn devices are polarity sensitive. They will not work with reversed polarity and most likely will self-destruct under this condition. If you have an unknown device, try it. You have a 50–50 chance of being correct. Most are positive, but a few are negative. If you have several surplus devices, check the circuit they came from for clues as to voltage polarity. If none are available, try them and hope for the best.

A sure giveaway of a shorted Gunn occurs when you apply DC power and it acts just like a 6/32 screw—a real ZERO dead short. A good Gunn will test like a a 2-ohm short, but when used in a cavity, it will only draw a certain amount of current, depending on the power rating of the device and its ohmic considerations. Some 100 to 200 mW devices draw 400 to 800 mA at 10 to 14 volts. A typical 10 mW device draws about 130 mA.

Gunn devices can test (ohmic) good, but not produce RF in a cavity due to poor cavity design or just a stubborn Gunn device. I have observed several troubles with Gunn devices, such as no RF output, shorted, and just plain cranky oscillators.

Testing Gunn Devices

With the Gunn device in a cavity, apply about 6 to 7 volts DC, taking note of the current which should be near normal for the power level of the device. At very low voltages the current might be excessive. Watch for microwave output and slowly raise the voltage towards 10 volts. Keep an eye on both the current and microwave output. The device will oscillate near its point of negative resistance. If it does not, make adjustments to your cavity circuit while watching for microwave output. Voltage should be set at or near 10 volts, but not higher for cavity adjustments. Once operation is OK, you can reduce the voltage to 5 to 7 volts and make a chart of the voltage vs. current readings. Your curve should look something like mine in Figure 3.

For brave souls who wish to determine the maximum voltage of their Gunn device, increase voltage slowly until there is no further increase in microwave output. Do not increase voltage above this point. Further voltage increases will result in device destruction. In most devices, the maximum voltage that can be used safely varies from 9 to 12 volts. You are TICKLING THE TAIL OF THE DRAGON AT THIS POINT. I do not recommend maintaining this voltage level for more than a short time. Back the voltage down about 1 volt.

I have destroyed many good devices by pushing this limit, and they don't give you a second chance. Keep the voltage at the setting for peak RF out or slightly less, and you will be OK.

IMPATTS Diodes

IMPATT diodes differ from Gunn diodes in that they have a diode junction and can be tested with an ohmmeter. They test just like a normal diode, checking for good front to back ratio. IMPATTS are current-fed, and as such are limited by a series resistor in the maximum amount of current they can draw. The power supply required for IMPATT diodes is much higher than that required for Gunn devices. IMPATTs require about 75 to 100 volts DC and current is usually limited to about 35 mA.

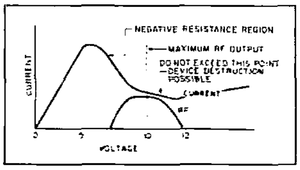

Figure 3. Gunn diode current vs. voltage curves.

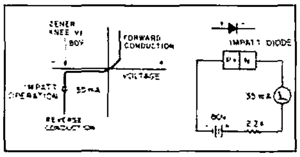

Figure 4. IMPATT diode operation. The IMPATT diode resembles a zener diode curve of operation. It operates in an avalanche current limited mode with 80 volts reversed biased at about 35 mA. IMPATT case style is identical to that of a Gunn device.

As noted, IMPATT stands for IMpact Avalanche Transit Time. Sounds like electrons doing their thing, rolling down the plank. However, the effect is part of an avalanche breakdown and the transit time of electron flow in the device (similar to zener action). It has to be controlled partly by device construction and by limiting current to a safe value. If current was not limited, the device would run away instantly and self-destruct. The breakdown regions of a zener and an IMPATT diode are nearly identical. Zeners can be made to operate as IMPATTs, but not all of them will function as IMPATTs, and those that do will be very inefficient.

I have several IMPATT oscillators, and they are very fussy compared to Gunns. Designing circuits with IMPATT devices can be very touchy, as several circuit designers demand tight guidelines in limiting substitutions between devices. They work well, but are critters unto themselves, and are not very design-forgiving. I have had poor luck replacing a defective IMPATT with surplus devices. However, using the IMPATT sources as they came from surplus, I have found them well-suited for beacon operation. This is due to a higher cavity *Q* and resultant frequency stability. If you want an IMPATT system I recommend you obtain a good commercial new or surplus device.

The surplus unit we found was manufactured by Raycon, part #10000-104-02, and provided 100 mW output at 80 volts/35 mA. N6IZW's beacon on Mt. Helix in San Diego County was based on this unit. The 10 GHz beacon, in use for over two years now, has worked well. The high *Q* cavity of the IMPATT oscillator helps minimize external influences, making the oscillator less sensitive to frequency pulling. Temperature, humidity, drafts, and the environment are all hostile to beacons, not to mention constant operation. The enclosure used to protect this beacon is a short section of plastic sewer pipe fully containing the oscillator and waveguide slotted antenna.

Mailbox Comments

Albert KC2MI of the Oneonta ARC in Oneonta, New York, writes that several club members would like to get started with microwave experiments, as that part of the radio spectrum is new to them. He reports that they were given several Gunn oscillators with defective devices. Albert is looking for 24 GHz equipment to place several stations in operation on that band as well. His address is RD #2, Box 325, Oneonta NY 13820.

Lyle Patison VK2LU is planning a talk on "starting out on 10 GHz" to amateurs "down under" at a local radio club. Lyle says he's been interested in 10 GHz operation for many years, and has a wideband unit (20 mW), and a narrowband transceiver (SSB, CW, NBFM) with 1 mW of output power. This unit injection locks a 30 mW oscillator for the final amplifier. The injection lock is accomplished using a circulator, and the resultant SSB output is quite good. He uses a 20-inch dish with a Cassegrain feed. He also runs a local beacon on 10.368270 GHz with 12 mW output that has EPROM identification.

Lyle's narrowband gear was home-built mainly from modified English designs. He is trying to get more activity on this band in Australia, hoping that talks at the local radio clubs will perk up interest.

Ace K5AR would like more information on toroidal transformers and spike reduction for the power supply project (see the August 1990 issue of *73*). I haven't found the answer in surplus on the transformers yet, but the spike reduction can be limited by the addition of a 0.1 µF cap and a series 5 ohm resistor from drain to ground. You might have to vary the capacitor value somewhat for maximum spike suppression. Observe on a scope and adjust the capacitor trimming for your switching rate.

I still have Gunn devices available for 6 and 10 GHz with 50 mW devices priced at $5 each, and devices up to 100 mW for $10 each postpaid. Additionally, I am looking for photo-multiplier tubes for use in a laser communications system that I'm building. Of particular interest are the types that use the top of the tube for input. Any help in locating the photo-multiplier tubes would be appreciated. When the system is in operation, I will publish full details on its construction.

As always, I will be glad to to answer any questions related to our VHF/UHF microwave bands or similar topics. Please send an SASE for prompt reply. 73's Chuck WB6IGP

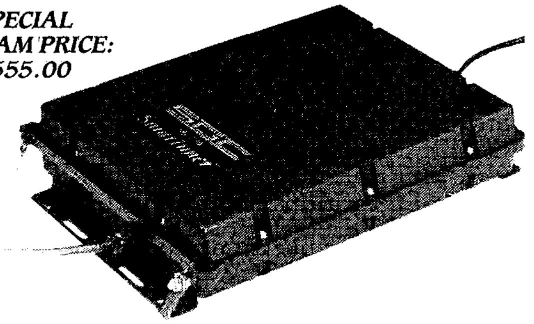
SGC SG-230

SMARTUNER

HF ANTENNA COUPLER—SSB, AM, CW & DATA
FAST—INTELLIGENT—ACCURATE
OPERATES WITH ANY HF TRANSCEIVER

The *Smartuner* high technology coupler intelligently tunes any length antenna (8 to 80 ft) in the HF band. This unit will operate with any HF transceiver within its' specifications. The *Smartuner* switches 64 input and 32 output capacitance combinations plus 256 inductance combinations in a "pi" network resulting in over a half-million different ways to ensure a perfect match for the transceiver. And, *it remembers the frequency and the tuning values* and will re-select these values in less than 10 ms next time you transmit on that frequency.

SPECIAL HAM PRICE: $555.00



Gordon West, WB6NOA, "the Smartuner is the best coupler I've ever tested or used"

- •MICROPROCESSOR CONTROLLED
- •NON-VOLATILE MEMORY
- •WATERPROOF
- •B.I.T.E. INDICATOR
- •1.8 TO 30 MHZ RANGE
- •10 TO 150 WATTS INPUT POWER
- •10 MS RETUNING TIME
- •8 TO 80 FT. ANTENNA (ALL TYPES)
- •FOR MARINE, AVIATION, HAM AND PARA-MILITARY APPLICATIONS

The SG-230 Smartuner is available from:

Eli's Amateur Radio, FL 305-525-0103 *Gordon West Radio, CA 714-549-5000*

CIRCLE 188 ON READER SERVICE CARD

HIGH PERFORMANCE PRESELECTOR-PREAMP

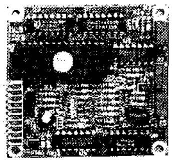
The solution to most interference, intermod, and desense problems in repeater systems.

- •40 to 1000 Mhz tuned to your frequency
- •5 large helical resonators
- •Very high rejection
- •Low noise—high overload resistance
- •8 db gain—ultimate rejection >80 db
- •GaAs fet option (above 200 Mhz)
- •Cast aluminum enclosure
- •N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs)   ±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs)   ±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- •Up to 8 EPROM programmed messages
- •Adjustable audio, speed & interval timer
- •"ID over voice inhibit"
- •Low power option
- •Modular design
- •Message selection via binary input—TTL levels
- •Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95   **ID-2B-LP Low Power $109.95**

Getting on AMTOR

Aside from the usual New Year's resolutions, such as losing weight and quitting smoking, here is one resolution you just have to see through: QRP AMTOR. Last April I treated myself to a new AEA PK-232 multimode controller, vowing that someday I'd give AMTOR a try. Well, that is exactly what I did, and I can say without question that QRP and AMTOR is a hard combination to beat.

I'm not going to try to explain AMTOR from the protocol level up, but rather share some good on-the-air experience I've learned through trial and error. Some of my mistakes might help others get on the air with AMTOR.

What You Need to Operate AMTOR

First, you'll need one of the multimode controllers. I picked the PK-232 because of the vast amount of software written just for it. You have your choice of the PK-232, the KAM all-mode, or the MFJ-1278 terminal unit. All of these are excellent and will work just fine for AMTOR. Besides the controller, you'll also need a computer or terminal unit. I opt for the computer, as you can operate dedicated software to really enhance the operation of the multimode controllers.

Some software programs are written just for a specific controller. In most cases, you can't use a program written for the PK-232 and expect the software to work correctly with an MFJ controller. Both MFJ and Kantronics offer specific software for their controllers. There are also third party software companies selling programs for any controller. Sometimes you can find outstanding software for a controller on a local BBS. CompuServe's HamNet has a huge data library full of programs for multimode controllers.

If you don't have a computer, that's all right, tool A dumb terminal will work, but you'll have to put up with the lack of specialized software. This means you won't be able to use split screens to separate transmit text and receive text. The dumb terminal will allow you to communicate to the multimode controller, and that's all.

Your Rig and Power Supply

You'll also need a radio that will operate full QSK break-in. Many of the newer rigs will do just that, but check carefully beforehand. I've used Ten-Tec rigs (both the Argosy and the Argonaut 509) and have had no trouble at all running AMTOR. In most cases, you can't use the break-in VOX; it won't switch fast enough for AMTOR. And, although this doesn't apply to QRP, if you run an amplifier, be sure it will also operate at full QSK.

Since AMTOR is almost 100% key-down (depending on your mode, FEC or ARQ [see next paragraph]; FEC mode IS 100% key-down, while ARQ is not, but it still demands a lot from the power supply), power supplies will be taxed to their limit. Make sure you have a good supply of cool air flowing around the transceiver and its power supply. Keep things cool, and you'll save yourself a lot of problems.

AMTOR Modes

AMTOR has two basic modes: FEC and ARQ. These are also called Mode B for FEC and Mode A for ARQ. Without getting into the why and wherefore of either mode from a protocol standpoint, all you need to know is this: To call CQ, use FEC or Mode B. This is a simple forward-error-correcting control for sending each character twice. FEC is used to call CQ, or for net operations and even for bulletins. FEC sounds very much like RTTY. In fact, after a while, you'll be able to tell by the sound of the FEC signal whether or not a station is calling CQ.

Mode A, or ARQ, is a synchronous system transmitting blocks of three characters at a time. ARQ has the characteristic chirp-chirp sound that makes AMTOR stand out on the bands. It is in this mode that you need full QSK for proper AMTOR operation. After you have called or answered a CQ, switch to ARQ mode. (To make life easier, if you call CQ and someone answers you, the controller will automatically switch over to ARQ, assuming the other station answers you in ARQ.)

This has been a very simple look at AMTOR. To get on the air and start making contacts is really quite easy. Be sure to get all the proper plugs connected to the multimode controller and the radio. This includes the microphone and audio out to the controller. Most AMTOR is on 20 meters, and in lower sideband, so you'll have to switch to the proper sideband if you want to start off with the right foot. On the Ten-Tec rigs, I have to choose the proper sideband by setting the MODE switch to SBPR. Also, with the Ten-Tec Argosy, the digital readout will now be off by about 2.5 kHz. Keep this in mind when trying to dial up a BBS on AMTOR.

From either the software or a dumb terminal, if you're using one, you'll have to include a SELCAL. This identifies your station. You *must* have a SELCAL, or AMTOR won't work! SELCAL is simple to add to the controller's memory. In most cases you drop your second letter and number from your call. For example, my call is WB8VGE and my SELCAL is WVGE.

With this out of the way, we can start. As I said, most of the AMTOR activity can be found on 20 meters, from about 14.070 to about 14.082, give or take a few kHz.

If your software will allow it, make up a CQ buffer or text file. Use the standard 3X3 call, but be sure to include your ARQ SELCAL! If you don't, no one will be able to sync up with your station. After you have a file or buffer, go to FEC and send the file. Your transmitter will come on-line, and you'll be in 100% key-down. After the file has run out, switch to standby mode and wait to see if you get an answer. If you do, you'll know instantly. The transmitter will start switching on and off very fast, and you'll be able to see what the other station is saying on the monitor.

If you get no response from your CQ after a while, tune up and down the band and look for a solid RTTY-like tone. This is an FEC. On the PK-232, tune until both the right-most and left-most LEDs are as brightly lit as possible.

The tuning indicator on the PK-232 leaves a lot to be desired, but after a while you can get the hang of it. When the FEC signal is tuned in properly, the controller will switch from standby to FEC. At this point, you should see something on the monitor. Look closely for the stations's SELCAL. When the station goes to standby, switch to ARQ and send *his* SELCAL. Your transmitter will start switching on and off, asking for the other station's SELCAL. When the two sync up, you're connected. At this time you can chat to your heart's content.

Perfect Copy at QRP

At this point, more than likely you're wondering what all this has to do with low-power communications. Well, with AMTOR, you get 100% perfect copy at very low power levels. I've had two-hour QSOs with DX stations running no more than one watt RF output! Of course, there were a lot of Repeat Requests (RQs) between the two stations, but we did manage to type away.

Running QRP AMTOR is slick! Things might slow down, but you can still hold a QSO. There are several things you should try to remember. First, since AMTOR generates 100% perfect copy on both sides of the QSO, you don't need to repeat anything! Don't ask "How's the copy?" when you know it's 100% perfect on AMTOR. LEARN HOW TO TYPE. Nothing is worse than talking with someone who can't type. Now this does not mean you have to do 80 words per minute, but you should do better than the 'ol hunt-and-peck method.

I also found out that you you can't adjust anything while AMTOR is running because of the rapid on-and-off switching of the transmitter. So be sure the SWR is correct, the power level is where you want it, and the audio gain is correctly set. I tried to adjust the antenna tuner while operating AMTOR. No way!

If you have not tried AMTOR QRP, you're really missing out on some great times. Give it a try. You won't be disappointed!

Coming Soon

Before we run out of space this time, I want to mention that I've got several really useful projects lined up for the upcoming months. The first project will be a universal T/R sequencer. This unit will control all the switching requirements that the active QRPer might need. The T/R controller will handle just about anything you can throw at it. I'm using mine for T/R controlling of an old Drake R4-B receiver and a host of home-brewed transmitters.

There are ample inputs for up to six different keying methods. These can include a straight key, bug, electronic keyer, and even a computer. All inputs are isolated from the transmitter/receiver circuits. You can adjust the T/R delay from the front panel as well as the internally generated sidetone. A separate T/R relay switches the antennas from a remote location. The entire circuitry requires 12 volts at 40 mA.

Best of all, all parts, and I mean ALL parts, can be purchased new from Radio Shack. The photos show two versions of the controller I use: One for the shack and the other for the workbench. Everyone should have one of these in the shack. Sure saves frustration when testing and building QRP transmitters. So get ready and heat up the soldering iron for next month. 73

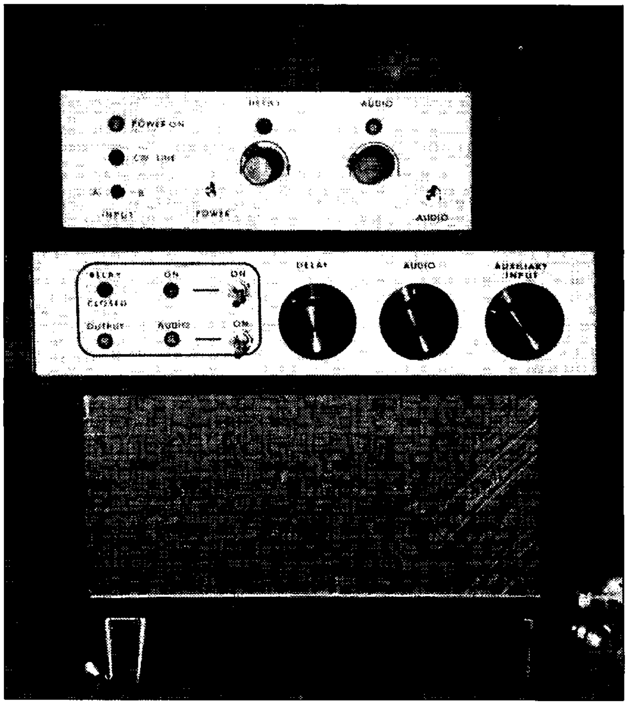

Photo A. Version one of the T/R controller every ham shack should have—next month's project!

HAMS WITH CLASS

Carole Perry WB2MGP
P.O. Box 131646
Staten Island NY 10313-0006

Ham Homeroom

Through a wonderful twist of fate, this term I wound up as the homeroom teacher for the top 8th grade class at intermediate School 72 in Staten Island, New York. I was excited at the prospecl of working with a group of gifted youngsters, but I was especially delighted to see the familiar names on the class register. Many of the children had been in my 7th grade ham radio program last year. Imagine my delight in learning that almost 50 percent of my homeroom students were licensed amateur radio operators!

What a year we've been having! By 7 a.m. many of the youngsters are at the classroom door, eager to get into Ihe shack. For 45 minutes every morning the young hams are busy swapping stories about their contacts of the night before, and looking up addresses in my callbook.

While I'm busily tending to the duties of a homeroom teacher, I delight in looking toward the station and seeing the kids having a ball on the radio. Almost every morning they greet the local hams on the 2 meter repeaters, and then move over to 10 meters and 20 meters. Inevitably, they get caught up in an interesting QSO, and they're still engrossed when the first period bell rings. I must admit I find it very difficult to admonish them about this.

Fortunately, their first period teacher understands the "pull" of the radio with these youngsters, and kind of looks the other way because he knows the kids are with me at the ham shack. One of Ihe benefits of having a successful ham radio program in a school is that the staff and administration become aware of the value of the program to the entire school. The children who have been in the ham radio program are always contributing interesting anecdotes and information to their social studies and science classes. There is a tremendous respect and appreciation by other teachers who know what the program can offer to the children.

Novice Follow-Up

It has been a real treat for me to be part of the follow-up for these newly licensed operators. Very often we lose the Novices after the course is over because they lose contact with a ham who can continue to work with them. By having them "under my wing" in the homeroom after they've gotten licensed, I can provide more follow-up activities for them and help steer them into the waiting arms of the local clubs.

The ham radio setup in my room allows the children to meet with each other and to have fun making contacts together. Some of these students don't have a radio at home yet. Since they've been given a chance to use the school equipment every morning, they've begun to realize how much fun getting on the air can be. Anyone who deals with youngsters knows that having fun is a contagious activity. Always try to provide the environment and ingredients in a learning situation for the children to enjoy themselves and feel good about what they're doing. Amateur radio can provide you with all the components needed to make every child feel special.

It's a good lesson for all of us to remember that it's important to provide the next step for Novices. Getting licensed is only the beginning.

What We Enjoy

While speaking to these highly motivated, terrific kids one day, I asked them what they enjoyed most about amateur radio. Perhaps you can share their responses with other youngsters.

Mary Alestra KB2IGG: Age 12, Extra Class. "There's no doubt about why the kids in our ham radio class at school are bright-eyed and perky in the morning. We all look forward to starting the morning with a contact on the air. All of us love the warm, welcoming good morning we receive from our many ham friends on the local repeaters. It's also a real thrill for us to make a contact overseas with a country we've been learning about in our social studies class.

"Many of the things we learn each morning at the school ham shack are helpful to us in setting up our shacks at home, and in learning how to operate properly and courteously. I also love meeting other kids on the 'CQ All Schools Net' and becoming pen pals with many of them.

"Here at Intermediate School 72 we know how to get going in the morning: eat a good breakfast and get ready for a great contact to start the day."

Mike Mlkos KB2JNB: Age 12, Technician Class. "Ever since I received my license I've made some exciting contacts. My rig is a Uniden HR-2600 putting out 25 watts into a Cushcraft AR-10. Some of my best DX contacts have been with Germany, Japan, Spain, Madeira, Portugal, Austria, Africa, Panama, England, and Italy.

"But one of my most memorable contacts, even though it wasn't a new country, was when I talked to a Cub Scout group in New Jersey. I loved talking to the kids and answering their questions about ham radio. I really hope I got some of those boys interested in the hobby.

"I've had my license for seven months and I haven't gotten tired or bored at all. I really enjoy it and I'm sure I will continue to have fun in the hobby for many more years."

Nicole Macellari KB2KXO: Age 12, Novice. "The first time I got on the radio was in Mrs. Perry's homeroom class. I was so scared. But Mrs. Perry stood right next to me and introduced me to Lionel KA2VBL on the air. He was so friendly and so nice that I forgot my nervousness and just enjoyed myself. I feel more confident every time I get on the radio now.

"Ham radio has been a help to me in many of my school studies. I recently had an interview for the Japanese Student Exchange Program at our school. I know that the fact that I had an FCC license was very impressive to the interviewer. I can now see why so many people are proud to be hams. Ham radio is fun for me, and I plan to upgrade soon."

Shaun Gartenberg KB2JNW: Age 13, Novice. "Ham radio is one of the most interesting and fun hobbies I have. There are so many people I've gotten to know on my ham radio. I really enjoy DXing on 10 meters. I find it very exciting reaching foreign countries.

"My father is also a ham. Many times we talk to each other when he leaves the house. Also, one of my best uses of ham radio takes place in school in Mrs. Perry's classroom. In case I've forgotten a book at home, I can call my father right from Mrs. Perry's ham shack. The other kids like to watch me when I do this. Ham radio is a great hobby for kids!"

Jared Greenberg: Age 13. "For the last two years at my school, I have not been able to get into the ham radio class. Fortunately for me, my homeroom class this year has many other students who have gotten their licenses, and my homeroom teacher teaches the ham radio course.

"When I first came into the classroom, I saw a lot of equipment in the back of the room which looked very complicated to operate. It seemed interesting, especially since Ihe other kids were always talking about it with Mrs. Perry. As the days progressed, I watched everyone as they used the equipment. It seemed like fun.

"A few days ago, Mrs. Perry invited me to the radio and began showing me how some of the equipment worked. She suggested I speak with a friend of hers on the air to see if I liked it. I remember how great I felt when the person I spoke to told me he liked the way I sounded on the air. Now I understand why people love speaking on the radio so much. With Mrs. Perry's help, books, cassettes, and lots of determination, I hope to obtain a license so I can speak on my own, as well as more often. I think I've found another hobby."

As teachers, we must never forget the enormous influence we exert on the lives of the children we see every day. Imparting knowledge is but one of the important things we do for our kids. Providing the environment for growth, both socially and academically, is imperative. Set up a ham shack where youngsters can operate and have fun together, then just stand back and enjoy watching the fruits of all your hard labors. It's what teaching is all about.

I recently saw the following article (see the sidebar) in a teaching magazine and cut it out and hung it over my desk at school. Please share this with other instructors and educators. It says it all. ■

All I Ever Really Needed to Know I Learned in Kindergarten

by Robert Fulghum
reprinted from *Kansas City Times*, Sept. 17, 1985

Most of what I really needed to know about how to live, and what to do, and how to be, I learned in kindergarten. Wisdom was not at the top of the graduate school mountain, but there in the sandbox at nursery school.

These are the things I learned: Share everything. Play fair. Don't hit people. Put things back where you found them. Clean up your own mess. Don't take things that aren't yours. Say you're sorry when you hurt somebody. Wash your hands before you eat. Flush. Warm cookies and milk are good for you. Live a balanced life. Learn some and think some and draw and paint and sing and dance and play and work every day some.

Take a nap every afternoon. When you go out into the world, watch for traffic, hold hands, and stick together. Be aware of wonder. Remember the little seed in the plastic cup. The roots go down and the plant goes up and nobody really knows how or why, but we are all like that.

Think of what a better world it would be if we all—the whole world—had cookies and milk about 3 o'clock every afternoon and then lay down with our blankets for a nap. Or if we had a basic policy in our nation and other nations to always put things back where we found them and cleaned up our own messes. And it is still true, no matter how old you are, when you go out into the world, it is best to hold hands and stick together.

Some of the students in my homeroom, left to right: Gabriel KB2KYF, Marc KB2KYJ, Shaun KB2JNW, Naomi KB2JRH, Nicole KB2KXO, Wendy KB2KXV, and Mary KB2IGG.

HAMSATS

Amateur Radio Via Satellite

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

Space Symposium 1990

Over 225 enthusiastic AMSAT supporters escaped the daily grind and "normal" ham radio the weekend of October 19–21, when the Johnson Space Center Amateur Radio Club in Houston, Texas, hosted the 1990 Space Symposium and AMSAT General Meeting. It was a great success, with the largest attendance since Los Angeles in 1984.

During the three-day period, 22 papers were presented on topics ranging from introductory information on getting started with amateur satellite activity, to scientific studies of AMSAT-OSCAR-13's orbital decay and microsat stabilization methods.

Most symposium papers were presented at the JSC Visitor's Center on Saturday, October 20, while the Friday and Sunday talks took place at the King's Inn adjacent to the space center.

AMSAT'S Future

Since the launch of four Microsats in January 1990, the amateur satellite community has been concerned about the direction AMSAT will take in the next several years. Funding for the ambitious Phase 4 geostationary satellite program has not materialized. AMSAT North America has not begun any new programs beyond software development for the current hamsats.

Phase 4 satellites would be long-life, stabilized amateur communications platforms at 22,000 miles out over the equator. The design, construction, launch, and orbital maintenance needs of a spacecraft of this type exceed the current resources available to AMSAT-NA.

Photo A. Allan Fox N5LKJ (one of Houston's AMSAT Area Coordinators) won the grand prize, an ICOM IC-275A, at the AMSAT Annual Meeting.

Dr. Karl Meinzer DJ4ZC of AMSAT-DL (Germany) presented a report on the Phase 3D Project supporting a new-generation, high elliptical-orbit, long-life hamsat. Although he did not submit a paper for *Proceedings*, he had an article, "Radio Links to Phase 3D," published in the May 1989 issue of *73 Magazine* in which you'll find many of the concepts of a high-power version of our currently operational A-O-13. Phase 3D could provide 6 to 15 dB better performance than A-O-13 from the VHF to microwave frequencies anticipated for the onboard transponders. A 6 dB improvement on our current Mode B (70cm up and 2 meters down) A-O-13 system would mean less antenna on the outside or no amplifier on the inside of a typical ham shack. For the higher frequencies with as much as 15 dB gain over current systems, signals could be heard and transmitted with small helix antennas or simple balcony-mounted yagis. This would be an advantage for those hams confronted with antenna restrictions or limited space.

Many experiments and transponders have been proposed for the new satellite. The communications equipment may range in frequency usage from 29 MHz to 10 GHz. Popular transponder configurations like "B" (70cm up and 2 meters down) and "L" (23cm up and 70cm down) would be supported, in addition to possible modes yet undefined. Experiments could include a camera, radiation and impact sensors, and an ionospheric experiment.

Participants in the new program would be from many countries. Countries currently represented include the U.S., Germany, Italy, Japan, South Africa, Australia, Hungary, and Yugoslavia. Others may join later.

Dick Jansson WD4FAB was prominently involved with the development of the Phase 4 concept and its physical design. His presentation, "The Phase IV Project—A Transition to Phase 3D," showed how AMSAT can apply much of the technology created for Phase 4 over the last three years to the Phase 3D program proposed by AMSAT-DL.

The cost for a Phase 3D satellite would be almost as much as for the Phase 4 satellite, but it would be shared internationally. Rather than go alone, with no funding, the AMSAT Board of Directors voted to discontinue Phase 4 efforts and support worldwide endeavors to make Phase 3D a reality.

The Decline of OSCAR-13

An item of exceptional interest and study has been the decline of A-O-13's orbit. The October 1990 "Hamsats" discussed findings on the eventual reentry of the satellite. Dr. Tom Clark W3IWI arrived at the AMSAT Space Symposium armed with charts, data, and some intriguing slides showing the mechanics of the situation in great detail. Using some very powerful computers, Tom was able to project different orbital scenarios into the future.

The current situation shows that the changes to A-O-13's orbit will cause the perigee or low point of the orbit to decline into the upper reaches of the atmosphere after 1995. Very small changes to the initial conditions of the launch or kick-motor firings could have had a dramatic effect on the orbit. One situation Tom described would have allowed A-O-13 to achieve a somewhat stable orbit with minimal perigee decline. Another possibility would have brought A-O-13 back to Earth within a few years, around 1992—much earlier than anyone would have guessed.

The Microsats

Many of the papers presented per-

Photo B. Gil Carman WA5NOM operates the hamsat station permanently located in the Visitor's Center.

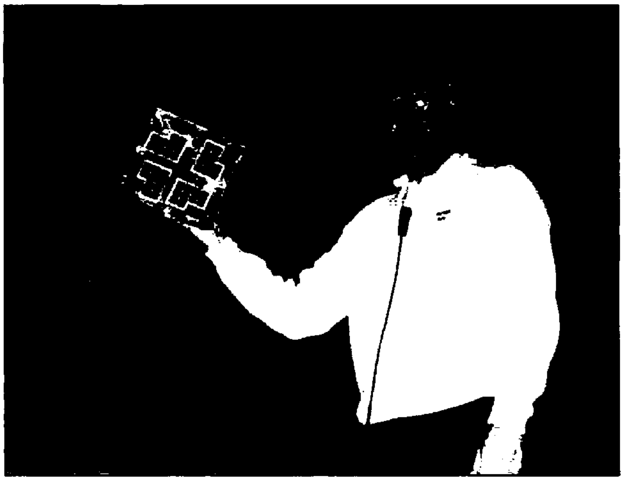

Photo C. Jim White WDØE explained Microsat motion, stabilization, and telemetry at the Space Symposium.

Photo D. Lou McFadin W5DID of the JSC ARC, and ham astronaut Jay Apt N5QWL of STS-37, with SAREX gear ready to go.

Photo E. Bill KB7KCM demonstrates antenna deployment of ADSAT to those at the AMSAT Space Symposium.

tained to the current state of the four Microsats launched in January 1990. The Microsats include AMSAT-OSCAR-16 (PACSAT), DOVE-OSCAR-17, WEBER-OSCAR-18 (WEBERSAT) and LUSAT-OSCAR-19. Much of the flight software has been difficult to develop, but the satellites are doing very well physically.

AMSAT V.P. Engineering Jan King W3GEY discussed the "In-Orbit Performance of Four Microsat Spacecraft." All design parameters of the program were met or exceeded.

A typical Microsat weighs 10 kilograms, generates 6 watts per orbit from its solar array, transmits a 2.4-watt output signal, rotates once per minute along its "vertical" or "Z" axis and stays at a cool 0.2 degrees Celsius.

Jim White WD0E addressed the issue of satellite stabilization, motion, and telemetry. Using a Microsat model, he showed how the satellites move and rotate relative to the Earth during each orbit. He also explained the importance of monitoring telemetry and described which parameters were measured onboard the spacecraft. Jim conveyed an in-depth understanding to the audience of how the Microsats move and function in orbit.

Steve Jackson WD8QCN, Chris Williams WA3PSD, and others from Weber State University explained the WEBERSAT camera experiments, the micro-meteor impact sensor, 1265 MHz video uplink receiver, horizon sensors, light spectrometer, and video flash digitizer.

Many digitized packet pictures have been received and displayed by enthusiasts, but the other experiments have not had the same level of publicity till now. As the students and staff at WSU gain more experience with the camera system, the pictures will improve and time will be allocated for work on the satellite's diverse functions.

David Liberman XE1TU presented a rather technical paper co-authored by Dr. Arcadio Poveda of the National Autonomous University of Mexico (UNAM). The paper and presentation described a Microsat project involving meteor-scatter radio propagation. While meteor scatter has been used by hams and others for communications between terrestrially-based stations, it has not been observed from the vantage point of satellites. Such a study will provide an opportunity for the UNAM to participate in a future Microsat project.

SAREX

It is hoped that by the time this is printed, STS-35 will have completed its mission with Ron Parise WA4SIR using packet and voice from orbit. Ron talked to the symposium attendees about the goals of his flight and the progress to date.

Lou McFadin W5DID brought the hardware for the Shuttle Amateur Radio EXperiment (SAREX) slated for launch with STS-37 in the spring. Two ham astronauts on STS-37, Jay Apt N5QWL and Ken Cameron KB5AWP, were available to talk with symposium participants about the mission. Lou's paper in the *Proceedings* provided real insight to the many challenges encountered in the course of satisfying NASA requirements to get a payload on the shuttle. The documentation requirements have produced a bookcase full of material just for the simple voice and packet station of STS-35. With the addition of SSTV and FSTV equipment for STS-37, the requirements were even more stringent. The SAREX volunteers have provided many hours of effort on the project. SAREX is a continuing project as long as we have hams on shuttle flights.

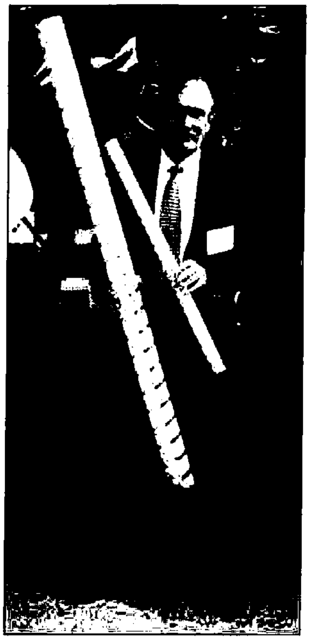

Photo F. Dick Jannson WD4FAB holds Phase IV helix antennas for 13 and 23 cm.

Additional Projects

During the weekend, the AMSAT Board of Directors considered many future amateur satellite experiments.

The work by AMSAT-Italy on ITAMSAT, an advanced Microsat, has passed the drawing-board stage with a nearly-completed flight-test model. Alberto Zagni I2KBD and his group have improved the original Microsat computer design. A launch in 1992 or 1993 is expected.

Other programs under study, or now entering the design phase, include SEDSAT-1/OSCAR, ADSAT, the Solar Sail, and efforts by AMSAT-Australia to work on a Microsat of their own.

SEDSAT would be an amateur radio device as a part of the Small Expendable-Tether Deployer System slated for a Delta-2 launch in a few years.

ADSAT stands for Astronaut-Deployable Satellite proposed for a shuttle mission. The project, conceived by Bill Clapp KB7KCM at Weber State University, has also been called pizzasat due to its similarity to an extra-thick pizza box with an antenna.

The Solar Sail efforts of the World Space Foundation need a communications and control system that could be designed by AMSAT along with a ham radio transponder system.

AMSAT Australia has just begun early design efforts, but has the capability to produce a Microsat.

You can find details of these projects and others in *Proceedings of the AMSAT 1990 Space Symposium*, available from AMSAT for $20.00. Write to: AMSAT-NA Headquarters, 850 Sligo Ave. #600, Silver Spring MD 20910-4703, or call (301) 589-6062.

AMSAT members can get the particulars of AMSAT programs and organizational changes from the minutes of the Board of Director's meeting as published in *The AMSAT Journal*.

Photo G. (Left to right.) AMSAT Director Tom Clark W3IWI reported on A-O-13's orbital changes and decline. AMSAT President and Director Doug Loughmiller KO5I fielded questions with Dr. Karl Meinzer of AMSAT-DL on the next generation of high-orbit amateur spacecraft. AMSAT Director Bob McGwier N4HY described both the AEA and TAPR DSP modems.

The Big Lie

This month, I was going to continue with last month's topic: getting young people excited about amateur radio. I got about halfway into a column suggesting different ways to make amateur radio exciting to kids, but my mind kept returning to the same thought: "Why write about getting kids excited about ham radio when the root problem goes much deeper. Why not just talk about the REAL problem?"

Here it is. The single biggest reason why there are not more young people involved in amateur radio in the United States is that the vast majority of active licensed radio amateurs do not want more young people involved in amateur radio.

That's right, folks. Mr. John O. Ham doesn't want to share his ham bands with kids. Judging by their actions, most hams are doing everything they can to keep anyone under the age of 21 from getting involved in amateur radio. In fact, most hams don't want ANY new hams. . .of any age.

Now, before the regular group of goofballs gets out their crayons and scrawls me nasty letters, let me say that yes, there are many individuals and groups of hams who are actively involved in recruiting youngsters for amateur radio. I mentioned a few of them last month. Yes, there are a few hams who do not have a prejudice towards kids, and they're doing great work. Unfortunately, these folks are a tiny minority of active hams.

The vast majority of our fellow radio amateurs do not want more youngsters in this hobby. Do you need proof? Bring a youngster to a radio club meeting. Go ahead. Do it. Then stand back and watch the outpouring of indifference showered upon this youngster by the members of this club. I've seen it with my own eyes, and I would be willing to bet that out of 20 club meetings there would be maybe one or two where someone would actually approach the child and welcome him to the club (that is, if the kid could stay awake long enough to get through the reading of the minutes of the last meeting, the 45 minute discussion about the purchase of $50 worth of coax, and the 20 minute argument about where to hold the club picnic this year).

You want more proof? Listen to any active repeater in any populated area. What happens when the sound of a young voice is heard? Hey, most hams in this country won't even answer a call on a repeater from another adult. The sound of a young voice must cause paralysis. Again, don't take my word for it. Next time you're in an area where nobody knows your callsign, pass the mike over to a young person and have them use your callsign to announce that they are monitoring. Nine times out of ten you'll hear silence, even on the most populated repeater in the area.

Hey, it's not only kids who get snubbed as newcomers at club meetings and on repeaters. I've sat through entire club meetings where not one person has asked me my name or whether or not I was a ham. Nothing! And yet, if you ask everyone at that meeting what the single biggest problem facing amateur radio is, you will probably get a unanimous response: growth. We can talk all we want about increasing the number of hams, but the evidence shows that we don't want any more hams.

Hell, the editor of another ham magazine recently admitted that he wasn't thrilled when his neighbor expressed an interest in becoming a ham. He asked his readers to tell him why he wasn't thrilled at the opportunity to share this great hobby with a neighbor. I'll tell him why. Could it be that he doesn't want any new hams living on his block, causing TVI, calling him up to ask for advice, borrowing his old equipment and having the fun that he's been having? God forbid, this neighbor might have a few grandchildren, or perhaps he works with the Boy Scouts or some other youth organization. What if this neighbor got his ticket and decided he was going to become an elmer for (gasp!) kids?

Ya' know. . .I'm a pretty tolerant guy. There are few things in this world that can get me really steamed. Most of them revolve around bigotry and dishonesty in all their various forms. That is why I am sick and tired of the amateur community giving lip service to increasing our ranks. It's a boldfaced lie, folks, and it's about time we stopped telling it to each other.

If we keep talking about getting more people—kids and adults—interested in amateur radio, why is it that we mostly do everything possible to keep people away? Until we come to grips with this elitist, bigoted attitude, any discussion of *how* to interest others in amateur radio is pointless.

Last month I suggested that with all the other high-tech marvels competing for a young person's attention, perhaps amateur radio was considered old news. What was magic to me as a twelve-year-old in the pre-computer era is low-tech to today's twelve-year-old computer hacker. But maybe the problem isn't getting the magic back into amateur radio. Maybe the problem is getting the magic back into radio amateurs.

Getting The Magic Back

Last month I asked you if you remembered the excitement you felt when you made your first QSO. For most of us, it was probably a CW contact on the Novice portion of one of the lower bands. Do you remember your first DX QSO? Was there someone there to help you get your ticket? Did someone hold your hand and walk you through what was then a strange, wonderful and frightening new world?

Amateur radio can be just as strange, just as wonderful, and just as frightening to a newcomer in 1991 as it was to you in 1940 (or 1950, or 1960, or 1970). Young or old, the excitement of that first QSO can be every bit as magic to a new Novice using a TS-440 as it was to you on an HW-16.

Have you lost that feeling of magic? Has ham radio become boring for you? Are you spending less and less time behind the rig and more and more time in front of the TV? Maybe you need to find that magic again, too. The best way to re-spark your own interest is to share it with someone. Pick out a few young people and share amateur radio with them. Make it fun. Build some antennas, put together a QRP rig or drag out that old boat anchor. Take a few youngsters on a mountaintopping expedition or camping trip. The next time your neighbor is standing on his lawn and staring up at your antenna, invite him in to see what's at the other end of that tribander.

If your radio club meetings are something you force yourself to attend, instead of the highlight of your month, find one other person who agrees with you and stage a coupe. Throw out the old men and invite the local Girl Scout troop to a meeting (that oughta' shake 'em up).

Plan a hands-on demo booth at your local mall. Yes. . .Hands-on! Let visitors to the booth actually sit behind the microphone and make a contact. Make sure to have RTTY for the shy folks. Don't forget a packet demonstration. Go out and actually solicit new hams. Are you retired? How about setting your station up at a local elementary school? All you have to do is ask. Talk to a science teacher and volunteer to demonstrate packet via satellite. Any teacher worth her tenure will jump at the chance to demonstrate what they're teaching.

If the magic has gone out of amateur radio for you, you can't blame anyone but yourself. Amateur radio is just as exciting as it ever was. You've just got to find someone to share it with. 73

January 1991 is not expected to be a stellar month for DX, with less than half of the days ranking only good or good-to-fair (see the calendar). Seven days will be downright poor, with the remainder trending poor-to-fair or fair-to-poor. Many alignments are taking place this month that will keep the ionosphere disturbed, and the magnetic field unsettled to active. Solar flux may be trending downward during part of the month as well, which won't help matters a lot. However, watch WWV carefully for trends on an hourly or daily basis for an upwardly moving solar flux and a downwardly moving "A" index. Let's hope February will be better.

The 80/75 and 40/30 meter bands should provide some good, low-noise activity in the U.S., Canada, and South/Central America, but DX will depend on a relatively quiet magnetic field. On the poor days, however, don't despair, since trans-equatorial skip and over-the-poles signals will be present. The polar paths will be weak and full of echoes, whereas the trans-equatorial path will provide stronger signals, sometimes even on poor days.

The 160 meter band ought to be good for much of the month, so watch the calendar for the good and fair days. The 20/18 meter and 15/12 meter bands will suffer the most along with 10 meters this month, so don't expect miracles. Perhaps in February we'll see some improvement, and March ought to get us back on the road to good worldwide DX conditions on all bands. Let's wait and see. . .de W1XU 73

LETTERS

From the Hamshack

Laci W1PL, Melrose MA Wayne, it was great to meet you and even more so to hear you talking to the New England DX people about the problems, the negative effects of the pursuit of the ARRL DXCC as it happens today. This problem bothered me also for a long time, discussed it with a few close friends, but we felt incapable and utterly powerless to even try to do anything about it.

You have proven so often that you see the future of amateur radio way ahead of the rest of us. It seems to me, the DXCC problems must be solved in some reasonable manner to keep it desirable, obtainable, and alive at all.

I know it is very difficult to change anything, but it could be done, I think, if valid DXCC credits would be given for QSOs worked only during the world's main contests, CQWW, ARRL DX, WAE, and AA. This would increase participation in the contests, concentrate the DXpeditions in those time frames, and would eliminate the discouraging, alienating effect of so many pileups with all the annoyances. The general ham population would enjoy operating in a more quiet atmosphere (ionosphere?). Even the rare DX stations would be free of that aggressive calling-hysteria, which chases the rare DX operator off the bands.

Immediately after the war, when I was practically the only HA station on the air, I lived quite a few years under the pressures of a rare DX. It was a bit easier than today, due to the lower powers, fewer beam antennas, and (may I say so?) snappier operators and more gentlemen. It still was often too much to take.

I leave my idea now with you, and please continue working for amateur radio's better future.

Thanks for your nice letter. I was wondering what impact my talk might have on the DXCC brethren. I had to get back, so I didn't hang around to see whether they would arrange a monument or tar and feathers.

One added benefit, as you mentioned... contest contacts would eliminate most of the QSL problems since they'd all be handled by computer.

Laci, I've changed amateur radio a good deal, so maybe I can do some more. I'm trying.

If I remember well, our first OSO happened 43 years ago! Hi!... Wayne

Kent Phillips WB8HWO, New York NY Wanted you to know *73* has followed me everywhere in the Middle East, and without your refreshing comments life would be rather dull. Keep up the satire only worthy of "Uncle Wayne." Please enter me in Ham-It-Up Sweepstakes; I'm only 6,000 miles from my nearest dealer.

Steve Katz WB2WIK/6, Canoga Park CA I've been following your "Never Say Die" editorials for years, and have also been reading the "Letters" section of *73*, which are far more interesting than the same section in competing magazines, for two reasons: One, the letters appear to be printed in full: and two, they often contain replies.

Actually I've been a Green fan ever since you were my first New Hampshire contact on 2 meter AM back in 1966 when I was a new Novice in New Jersey running a Heath "Twoer." To make a contact with NH using about 1.5W output to a little 8-element yagi—a 250-mile path over hilly terrain using terrible equipment on my end—was such a staggering accomplishment that it turned me on to VHF/UHF for life. I believe on your end, you were running high power and an enormous collinear antenna part way up Mt. Monadnock. You used to generate pileups among us "lowland leaf-lookers" in NJ and PA.

In the December *73* "Random Output" by David Cassidy, Dave recalls the magic of wireless communications and how the newcomers to the hobby might miss out on the feeling. I agree. It's sad that most new hams are such appliance operators; they never think about what goes on inside their equipment to make easy QSOs possible. Anybody who hasn't home-brewed at least one complete setup, or at least a simple transmitter, doesn't know what he's missing.

Over the past 25 years, I've upgraded to Extra (I love CW, anyway; color me crazy) and home-brewed dozens of stations, sometimes including complete receivers (what a job!) and often of my own design, good or bad. All my kW amplifiers are home-brewed, except for one Henry Radio RF deck using a 3CX1200D7, and I built the power supply for that. Now, living in a townhouse in Los Angeles, after owning several homes on large lots back East, I enjoy the challenge of working DX using small antennas, or going hill-topping to work VHF DX. There are always a million challenges! To sit in front of one's store-bought transceiver for hours on end cannot be anybody's idea of a thrill... can it?

I agree with you, we need more young blood in amateur radio. It does seem that most of my CW contacts are with retired folks who learned the code before or during WWII. Even the world-class contesters, presumably the best operators in the world, are getting older. Who will replace them, to set new standards? Who is going to be the first to make 300 QSOs/hour in a contest? Work DXCC in 60 minutes? Develop systems to make packet meteor scatter contacts a daily occurrence? Keep pushing for less restrictive legislation regarding antenna and tower zoning and ordinances? Design the new amateur equipment? Distribute and sell it?

There's far fewer ham stores in America than ever in my personal tenure. I don't see how any of them make it. I'm lucky enough to be within a one-hour's drive on crowded freeways to not just one or two, but *five* amateur radio outlets. This may exist only in Los Angeles. Used to be, New York City alone had a dozen—but I believe only Barry remains. And do the "locals" support their local dealers? Not by a long shot! Most folks around here would rather mail-order their gear to save the sales tax. Big deal! They probably save $35 on a $1,000 purchase when the shipping costs are added in.

Then, the average ham is looked upon as a weirdo by the rest of society, anyway. Many are socially inept, severely introverted (except on the air). Some are bona fide sociopaths! (Just listen in on a couple of the wide-coverage L.A.-area repeaters.)

What can we do to generate interest among the youngsters, who might be able to save ham radio? For starters, we can get our own kids interested and licensed. Every licensed amateur who is a school teacher at any level should introduce the wonders of wireless communication to his or her students—maybe even convince the board to make ham radio an accredited class. Every active ham who is a radio club member should bring one non-ham to the next club meeting, and make the effort to introduce that person to the gang. Make an issue of it, with formal introductions and the rolling out of a great, big welcome mat. We have a great hobby for retirees, but licensing the old-timers will not help the service survive. Only the kids can do that.

Every time I have a youngster in my car, for any reason, I don't ignore the two transceivers installed therein. I pick up the mike and make a few contacts, explaining to the visitor what's going on and how much fun it is. Their eyes open wide as they hear the foreign accents rolling in on my 10 meter rig, and get wider when they hear an Aussie or Slav respond to my call. "How's the weather there in Belgrade, old man? Do you do any skiing on all that snow?" "Do you guys in Sydney really use boomerangs to get your dipoles up in the trees?" Make it interesting! The kids are guaranteed to go nuts, asking questions about how to get licensed.

I show my limited DX OSL card collection (about 100 countries are hanging on the wall—the most interesting cards I could pick out from my collections, with bright colors and bold descriptions of the DX locations) to practically every single visitor to our home. Since everybody here in California is from someplace else (or so it seems!), I ask each new acquaintance where they're from, and try to show them one QSL card from that place, stating proudly, "Oh, yeah, I know this guy Sam from there. He's an avid fisherman, and pulls the big trout out of Lake Whatchamacallit." They are absolutely dumbfounded. Maybe one in five will ask some questions about ham radio... then they're hooked.

My eight-year-old nephew, better traveled than most because he was born in the Middle East, lives with us. He's probably the only third-grader in his school who actually knows where all the DXCC countries are, along with the names of countries no longer in existence, and what's taken their places. With mildly incapacitating cerebral palsy, his coordination is not great, but he can copy 5 wpm and get most of it down on paper. A Novice ticket can't be more than a year away—probably closer—for him. He's the only eight-year-old I know who can answer nearly all the "World Geography" questions on Jeopardy! He's also getting a grasp of simple algebra, which won't be taught in his school for another two years, based on his interest in Ohm's Law.

There are as many ways to get youngsters interested in radio as there are youngsters. One only needs to take a bit of time to find the right button to push. I compel anyone interested in the future of amateur radio to look for those buttons, push them, and keep on pushing until all the neighborhood kids have their tickets.

I know you're not just trying to sell more magazines, Wayne. There are lots of easier ways to make money. If the hobby were healthier, really booming, *73* could be free, paid for entirely by advertising revenues. Keep up the battle. Some really are listening. And thanks for being my first 2 meter DX contact, 25 years ago. I still remember.

Thanks for taking the time to write such a great letter. I wish more hams would do that! I'll be publishing it... hoping that maybe you can get some of these tired old geezers off their butts.

Good news: I'm getting closer to getting NH to set up my electronics education course. This could turn out 10,000 hams a year. Just from NH!... Wayne

Trevor M. Artingstoll G0JOE, UK So Ole Ozzie KA1BIK is the other guy left on the planet with radio dust infection? I suggest we manufacture the drug and peddle it in schools and institutions of higher learning. I'd pay $100 for an inhaler packet with the stuff, myself. Imagine, in a dull moment, unscrewing the little plastic cap, inserting the tube delicately into the waiting nostril, and—kepow!—back to the Land of Glowing Bottles—searching in the coal box for gold streaks to stick in a crystal set—wrecking basket coils for the hell of it—soldering real, honest-to-God, *solid* copper wire seductively wrapped in cotton—drilling ebony wood front panels—! But I speak a foreign language to young and middle-aged hams. Sigh! There's no cure, you know.

David Terrell KB5LAM/AA Thanks for producing a high-quality product. I weighed *73, CQ, QST*, and *World Radio* in the balance. *73* has the best mix of the things I want to see. I devour the technical issues and construction articles. I also enjoy the human side about clubs and individuals. I've requested the writing quidelines you've established and intend on trying my hand in both areas.

Lowell E. Robertson K6QXQ, Riverside CA I am rather slow at responding to the article, "Rad Radiator," in the May 1990 issue of *73*. I just want to comment that the wire hanging down from the bottom of the walkie-talkie creates a variation of the "counterpoise" antenna which may be a long forgotten antenna type. This may sound critical of an otherwise well-written article, but the term "counterpoise" has a more professional ring than "rad radiator."

Richard Ernst /EA7, FPO NY Three months ago I purchased the new *1990 ARRL Handbook* at the cover price of $23. Table 42 on pages 35–38, and 39 contains the "ARRL Parts Supply List." Being an avid home-brewer of just about everything, and being posted overseas, I said to myself, "Rich, here is your source of mail-order parts." I sent 12 letters to companies on this ARRL list, and as of today I have yet to receive the first reply. After 26 years I guess I haven't learned my lesson yet. Caveat ??

NEVER SAY DIE

Wayne Green W2NSD/1

Scrambled Brains

Some years ago in one of my usual feeble attempts at humor I suggested that since we seemed to have far more bad operating problems with our Extra Class hams than with others, maybe the Morse code had scrambled their brains. One advertiser, with a sense of humor down in the molecular range, canceled all his ads in *73* in retaliation. Well, that means you readers have been out about five good construction projects a year that these ads would have made it possible for us to publish, and the advertiser has thrown away around $200,000 a year in sales. I have to admire such strong convictions, no matter how misplaced.

I know you're hoping I'll digress with more irrelevancies, but no, I'm going to get back to the subject at head. Okay, for those few readers who are borderline illiterate . . . in other words, who do not subscribe to *The New Yorker* magazine . . . I've some news. Paul Brodeur, the chap who wrote a three-part series in the same magazine last year about the effects of weak electromagnetic (EM) forces on cells, has been at it again. Look for his book, *Currents Of Death*.

ARRL stalwarts who bothered to attend the 1989 League convention had the opportunity to hear Dr. Ross Adey K6UI give a remarkable talk on the subject. I recently watched a video tape of his address . . . something every ham club should put on their program. My tape came from WA6PMX. Ross is one of the leading scientists working in this field . . . another feather in the cap of amateur radio.

The latest Brodeur *New Yorker* article picks up from where he left off the year before. It turns out that not only do incredibly weak EM forces have very measurable effects on cell growth and communications, this is exacerbated when there are switching transients involved. Square waves.

The human statistics back up scientific experiments with mice and chicks. Women who use electric blankets are having a greatly increased incidence of miscarriages and malformed children. There's a strong link to cancer, too. My first solution to this was to suggest rectifying the current and making it DC. Nope, as long as you have those infernal thermostats turning the DC on and off all night, you're hitting your whole body with square waves. Bad news.

Brodeur reported on the incredible incidence of brain tumors across the street from a power substation in Connecticut . . . and the high incidence of tumors among power company workers. We see a similar higher than normal incidence of cancers with hams. Ross pointed out in his talk how the League flatly refused to cooperate with research aiming at getting this information.

This opens up some very serious questions for us. First, there is a need for you to make sure that you elect a new director, one who will force the League to cooperate with researchers in studying such matters. I can understand why the League has a vested interest in trying to cover this up. This is the same route taken by the tobacco industry when it was suggested that cigarettes might be harmful. That industry still isn't convinced.

But let's suppose that the obvious is actually true . . . that the powerful square wave EM field our transmitter generates when we send Morse code does affect the cells of our bodies and brains to some degree. Our systems do a heroic job of repairing damage done by carcinogenic materials we eat and breathe. But can we really expect this repair system to be able to cope 100% with powerful and extended daily blasts of EM energy which screw up cell growth and communications in our brains and every part of our bodies? I'll be surprised if we don't find that dedicated CW operators . . . particularly those running some power . . . aren't dying far faster than our actuarial tables predict. Our beloved, worshipped Morse code could well be killing us.

Even More Bad News

Okay, we can see where we might be in trouble when we're transmitting, but at least we can receive code without worrying, right? Oh yeah? When you're receiving Morse at 20 per, that's at about 6.4 Hz. You're blasting your brain with a 6.4 Hz set of square waves. We've isolated several of the operating frequencies of the brain and they're all in the low Hz range.

Is it really just a coincidence that such a heavy proportion of the troubles we've been having in amateur radio seem to be with Extra Class operators? Is it entirely a coincidence that almost none of the Bash-licensed Extras are in trouble? We know that a high percentage of the Bashers never had to bother learning the code.

The personality changes which the code may be making in us would occur slowly, over a period of years, so families and friends would come to accept them, no matter how bizarre they are. Wives somehow manage to get used to DXers putting a new country before the marriage, children or even making a living.

Ham dealers joke about hams being crazy. Do we become hams because we're crazy or vice versa? No, I agree, not all hams are crazy. I don't think I am, but you know I'm not going to ask for a second opinion. Is it mainly Extras and their 20 wpm code? How much of an effect can 13 per have? Maybe we can accept amateur radio only partially addling our brains.

I know this, I'm keeping my linear amplifier far enough away from my operating position so I'm not going to be milligaussed and square-waved. I'm going to steer well clear of Morse, both receiving and transmitting. I suspect that frequency-shift keying may be far more benign.

You may be sure that I'm going to keep HTs with subaudible tone generators far away from my body. Ross has published some frightful charts in scientific journals showing what a 450 MHz HT with a 16 Hz tone can do to cells.

An Opportunity

As the media begins to understand the extent of the damage being done to people by electromagnetic radiation, I'll be surprised if they don't jump on this gloom and doom bandwagon and scare the public silly. This should open an opportunity for entrepreneurs to offer degaussing services.

You can build or buy a milligaussmeter pretty reasonably. As the demand goes into panic mode, we'll go through the usual shortage/glut roller coaster ride. With a meter and some understanding of EM, entrepreneurs should be able to set up some very profitable businesses.

If you think old Uncle Wayne is pulling your leg, check out *Time*, July 30th, page 53. I do my homework before I write, even when it means wading through a pile of heavy duty research journal reports. I'll put the bibliography on the *73* BBS, if you'd like to check it out.

From what I've read so far it seems very likely that further research could show that CW ops running a couple hundred watts are getting a carcinogenic blast of EM which is equivalent to smoking a pack or two of cigarettes a day. This stuff is insidious, like cigarettes. It won't kill you in a day or a week, but slowly, over a period of years, it may be changing your personality (not likely for the better) and shortening your life. I feel tremendously lucky that I changed to frequency-shift keying 40 years ago.

The Bottom Line

So it looks as if Sam Morse didn't do us any favors. The code not only has little place in modern radio communications, it may well be damaging our minds and bodies and sending us to an early grave.

As Ross pointed out, anyone who says this is controversial is ignoring incontrovertible facts. But I can understand an urge to dismiss bad news. There must be some mistake. Our government wouldn't let us use electric blankets if they were dangerous, right? Sure, like they don't let us drink alcohol and they don't let us smoke. When the dollars involved are big enough, Congress will go along with the money, no matter how many people get killed.

Our Cells

If you do some homework you'll find that our cells work on a combination of electrical and chemical reactions. They are busy working and duplicating themselves, all as part of a cooperating group. They communicate electrically, using low Hz frequencies. The duplication process involves the magnetic transfer of information as DNA molecules copy and split. Part of this is chemical, part electrical, and part is magnetic.

We can interfere with this process with drugs and interfering magnetic fields, but the body only has so much ability for self-repair and when eventually we exceed that the cells go berserk. Cancer. Tumors. Miscarriages. Deformed children. Children with damaged genes which may not kick in until years later. We'll know more about those effects as the Genome Project progresses.

If you think Wayne is full of baloney on this one, do me a favor. Go back through my 40 years of editorials and show me where I have ever been wrong on a scientific matter.

Flaplet

If you don't read the ARRL HQ BBS you missed a great item telling how angry a couple of ARRL officials were at the recent Houston Ham Com. They were mad because their ARRL booth for selling *QST* subscriptions and League books wasn't allowed free into the paid vendor area. They were further steamed when they were refused

EDITED BY LINDA RENEAU KA1UKM

No Code At Last!

On December 13, 1990 the first no-code amateur radio operator's license in the U.S. was approved by FCC Bureau Chief Haller and Commissioners Cross, Quello, Duggen, and Sykes. Docket 90-55 establishes a codeless license by eliminating the code requirement for the Technician class license. This is the first no-code license in the history of the U.S. Amateur Radio Service.

Applicants for the new Technician license will have to take the theory exams, a total of 55 questions, required for both the Novice and Technician class licenses. The new Technician will be granted all privileges on all frequency bands currently allowed to Technician class license holders, but only for operation above 30 MHz (6 meters and above).

For existing Technician class license holders, nothing changes. Technicians licensed before the implementation of the new codeless license will be grandfathered to protect their earned HF operating privileges, including 10 meter radiotelephone. The Novice class is also unaffected by this change.

The new Technician will be able to experiment with exotic modes, own repeaters and remote base stations, but not participate in HF operation unless HF privileges are gained by passing the 5 wpm Morse code test through the VEC system.

Originally, the FCC had proposed the phasing out of both the Novice and Technician classes, claiming widespread cheating in Novice testing and a general need to save money. The ARRL said the abolition of both classes was unacceptable, and several VECs offered to bring Novice testing, at no cost, under the VEC system. At FCC conventions, the media demanded proof of the cheating claim, which the FCC failed to provide. Also, individuals and groups presented the FCC with information that refuted their budget-saving argument.

In the end, the FCC opted to follow the suggestions of the Quarter Century Wireless Association (QCWA). They retained both license classes and modified the requirements for a Technician class license to create a code-free entry into amateur radio. Many of us hope that this will increase the growth of amateur radio without decreasing the quality. Says Bureau Chief Haller, "Morse code does not prove what kind of operator you are going to be. It only proves that you can send and receive Morse code! We [the FCC] are retaining a written test. There is a license that can be lost for. . . violation of the rules. . . ."

All five FCC commissioners agreed that passing Docket 90-55 will keep the nation at the forefront of communications research and development, and help recruit technically inclined people into the Amateur Radio Service.

There will not be any call-letter distinctions between the old and the new Technicians. It will still be up to the amateur community to police its own ranks.

Most experts feel that full implementation could take place as early as February 1, 1991. *TNX Bill Pasternak WA6ITF of Westradio and Amateur Radio Newsline, and Paul Courson WA3VJB, Washington correspondent.*

Docket 90-356

The above FCC commissioners also passed Docket 90-356, the CW waiver for certain handicapped individuals. Passage of this docket exempts handicapped persons from the high-speed code exams if their physical condition makes it impossible for them to learn code at the required speeds. Commissioner William Cross says that the FCC "will rely on a physician's certification of disability to determine eligibility of an applicant."

Private Radio Bureau Chief Ralph Haller W4RH said that relaxing code requirements for the handicapped, along with establishing the new codeless Technician license, will promote further growth of amateur radio. During the presentation, Chief Haller held up a 2 meter HT and declared it a symbol of the vital role amateur radio plays. He said that because of amateur radio operators volunteering their time and personal funds, ". . . it is possible to communicate essentially around the world with a small radio like this! It gives you an idea of the dedication of these amateurs to the advancement of the radio art."

Commissioner Quello stated his personal feeling that it was definitely time to open the gates of amateur radio to those who may not be able to master the Morse code. He noted that today, "Most [communication] is by voice, anyway."

Commissioner Irvil Duggen said, "There was some fear in my mind [at first], that we might be leaning over too far backwards in relaxing our standards, and that in trying [to be] compassionate and responsive to the special needs of handicapped people, we would in fact rob them of the pride that they might otherwise have in being able to meet tough standards. . ." But the hundreds of comments the FCC received from people and groups "removed that concern."

Chairman Sykes said that "The steps we took to broaden [the Amateur Radio Service]. . . holds the potential to provide an even more vital and dynamic service."

All five commissioners voted unanimously on both agenda items: Approving CW waivers for handicapped hams who want to upgrade, and dropping the CW requirement for the Technician class license. *TNX Bill Pasternak WA6ITF of Westradio and Amateur Radio Newsline, and Paul Courson WA3VJB, Washington correspondent.*

The ARRL's Response

Subject: ARRL No-Code Reconsideration. The ARRL applauds retention of the Novice license and seeks input on privileges for codeless technicians.

Responding to the Federal Communications Commission action PR Docket 90-55, creating a codeless class of amateur radio license, the president of the American Radio Relay League, Larry Price W4RA, noted with pleasure that the Commission had decided to retain the Novice license as a means of entry into amateur radio and to adopt a codeless license with a meaningful written examination requirement. "Our members were very strong on both of these points, because they couldn't imagine how we could maintain the character of the Amateur Radio Service without them," Mr. Price said.

However, President Price sounded a note of caution with regard to the privileges the Commission plans to grant to the codeless licensees. "The formula developed by the ARRL Board of Directors, which called for privileges above 220 MHz, was based on extensive membership input. It was carefully balanced to offer attractive privileges while protecting existing patterns of amateur activity."

While it will take some time to gauge the reaction to the Commission action, Dr. Price observed that the FCC formula is likely to be less acceptable to many amateurs than the League's. He asked that League members share their views with their elected directors, who collectively determine League policy.

"Before we can decide whether to request that the Commission partially reconsider its action, we'll have to see the Report and Order," said Mr. Price. Usually it takes the FCC from several days to several weeks after a Commission action to release an item after editorial review. There is a 30-day window of opportunity following release in which petitions for reconsideration can be filed. Mr. Price noted that the ARRL Board is holding its regular meeting January 18–19. "The timing looks good for a careful review of the Commission's action at that meeting," he said.

For further Information contact: David Sumner K1ZZ, tel: 203-666-1541; Fax: 203-665-7531. *TNX Bill Pasternak for sending us this Amateur Radio News Release from the American Radio Relay League, Inc., via MCImail on Dec. 19, 1990.*

QRX . . .

Persian Gulf Rands

Nearly 400,000 U.S. troops in the Persian Gulf means increased military communications on the HF bands. Here are some USAF Global Command and Control System (GCCS) frequencies in kHz, USB:

•Loring AFB, ME: 3074, 6738, 8964, 11179, 13214.

•MacDill AFB, FL: 4746, 6750, 8993, 11246, 11288, 13244, 18019.

•Ascension Island: 6750, 8993, 11176, 13244, 15015.

•Croydon, UK: 3067, 5703, 6750, 9011, 11176, 13214.

•Incirlik, Turkey: 3137, 6738, 11176, 13214, 15015, 23227.

The Saudi Air Force can be heard on 3095, 5526, 8967, and 8990. Dharan Air Base has been heard on 9130 and 11100, using the callsign "Hotel 1"; Riyadh "Hotel 2" is on 7300 and 12112. The U.S. Army Corps of Engineers in Saudi Arabia are on 9130 and 11425, using callsigns "Castle 1" through "Castle 8". 11300 is another active frequency in the area. The United Nations forces are assigned the following sets of frequencies:

•Primary: 6632, 9006, 11233, 13231, 13257.

•Secondary: 4704, 5690, 6204, 6810, 6905.

Middle East air traffic controllers for the Gulf Region operate on: 2992, 3404, 5603, 5658, 5667, 8847, 8918, 10018, 13288, 13312, 13336. In the gulf and nearby waters, the U.S. Navy has been heard challenging commercial vessels. The most active channels have been 4125, 1413, 4419, 6218, 6519, 6521, 8291, 8294, 12492, 12435, 16587, 16590, 16593, 22105, 22124, 22127, 22130, and 22136. Also check out their HICOMM channels on 7525, 12215, and 23315.

And remember, don't CQ Kuwait. A QSO with a Kuwaiti amateur could cost him his life. *TNX* Nashua Area Radio Club Bulletin, *and Ed Brown KB1MZ in particular.*

SAREX Success!

Over 500 hams were able to communicate with Ron Parise WA4SIR during the recent STS-35 space shuttle mission. The robot packet experiment was a success with 238 stations worldwide completing two-way packet contacts. Several hundred more were at least heard by the shuttle. Quite a few voice contacts were made, primarily in Australia, South America, and South Africa. A number of scheduled voice contacts were made as well during the evening passes over the U.S. Twenty-eight school groups in the U.S. had a chance to talk with Ron, via a telephone bridge to the uplink sites, while he was over Australia and Brazil.

A QSL will be issued to those who send in any received packets from the shuttle (QRZ logs). Please include the date/time of the reception. This information will help determine all of the stations who made one-way connects up to the shuttle. Please send your receive buffer files to the ARRL, Attention: Rosalie White, 225 Main St., Newington CT 06111. It would help to send an additional copy directly on packet to SAREX @ W3IWI.MD.USA.NA (or via internet mail to: sarex@tomcat.gsfc.nasa.gov).

A complete wrap-up of the STS-35 mission along with news of the upcoming STS-37 mission will appear in the March issue of *73*. *TNX AMSAT and WB8ELK.*

Get Rich—

—beyond your wildest dreams! Or, at least make a few bucks for yourself or your club.

The staff of *73* tries to get to as many hamfests as we can, but there are plenty we miss. That's where you come in. We'll pay you (or your club) to run a *73* booth for us. It's easy. We'll send you everything you need. You staff the booth and take subscription orders, and we'll give you a cut for every order you take. That's cold, hard cash! Up front. At an average hamfest, you should make a couple of hundred. Not bad for a few hours' work—plus, you'll get the personal satisfaction of sharing *73* with your local ham friends. OK, forget about personal satisfaction—do it for the dough! Just call Donna DiRusso at (603) 525-4201. *From the staff.*

TNX . . .

. . . to all our contributors. You can reach us by phone at (603) 525-4201, or by mail at *73 Magazine*, Forest Rd., Hancock NH 03449; and by e-mail on CompuServe ppn 70310,775, MCI Mail "WGEPUB" and the *73* BBS at (603) 525-4438 (300-2400 bps), 8 data bits, no parity, one stop bit.

Boy Scouts from Troop 73, Springfield, and Troop 94, Hillside, New Jersey, participated in the 33rd annual Jamboree On the Air, or JOTA, last October, when thousands of hams opened their stations to scouts. Above, at the Watchung Reservation in Mountainside, New Jersey, Springfield Emergency Management Staff KB2KOQ, KB2KEC, WA2WUX, WA2QNZ, KB2KEC, and WA2BAT (not in photo) set up a temporary outdoor radio station using a Kenwood TS-430S and long-wire Windom antenna.

Radar Detector to Microwave Receiver Conversion

Listen on 10 GHz, cheap.

by Steve J. Noll WA6EJO

The abundance of so-called "police radar detectors" made me wonder if these devices might have a useful application for the amateur microwave experimenter. These self-contained receivers are designed to detect police speed-measuring radar energy around 10.525 GHz (also 24.125 GHz in K-band), just above the 10.0 GHz–10.5 GHz Amateur Radio Service allocation.

Although there are plenty of these devices on the market, many of them are expensive for experimenting with. However, C.O.M.B. Company had been selling the BEL XKR series detector for very reasonable prices. I just couldn't resist! (The C.O.M.B. Company is located at 1405 Xenium Lane N., PO Box 32, Minneapolis MN 55440-9176. Tel. 800-328-0609 or contact BEL-Tronics, 20 Center Dr., Orchard Park NY 14127. Tel. 716-662-0522.)

I opted for the BEL XKR-IX Micro-Eye model although any of the XKR series should be similar. The Micro-Eye is a dual-conversion superheterodyne X-band and K-band detector. Although this article applies specifically to this particular model, other modern detectors may be usable, too.

Inside the Micro-Eye

The Micro-Eye is housed in a 1.25" x 4.25" x 4.5" two-piece plastic case. Opening the case proved to be the most difficult part of the entire project! It's glued shut. Careful and persistent prying with a knife will separate the halves to reveal the high-quality electronics inside.

The detector's circuitry is divided between two printed circuit boards. One board contains the controller section of the detector (not used for this project). The other contains all of the RF circuitry and a horn antenna. These two boards conveniently plug together via a 6-pin connector. See Photos B and C.

The controller printed circuit board contains a couple of comparator ICs (MC3302 and LM393), an LM358 dual op amp, and a 78L05 voltage regulator. A custom controller chip appears in the center of the board. About 60 discrete components round out the circuitry.

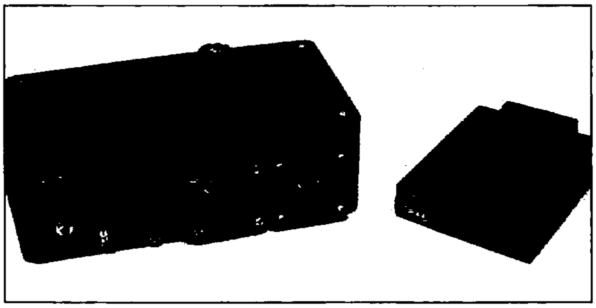

Photo A. The finished product (left) and the original radar detector (right).

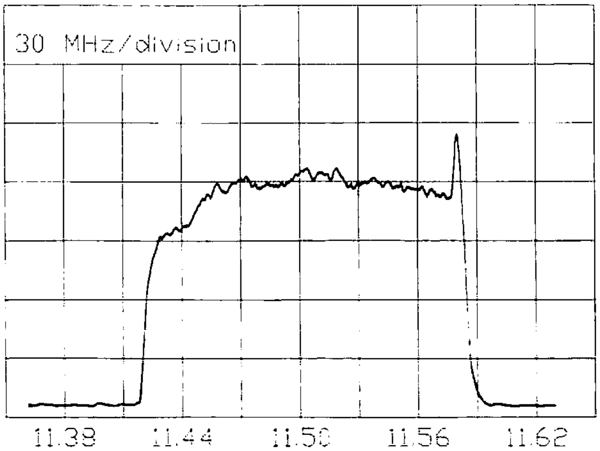

Figure 1. This plot shows the detector's VCO sweeping from 11.4 GHz to 11.6 GHz.

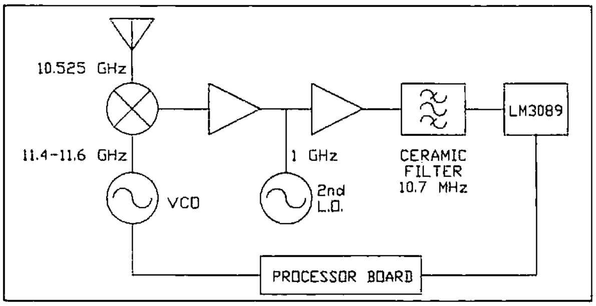

Figure 2. Block diagram of the radar detector.

Metalized, molded plastic covers most of the RF circuit board and forms three sides of the horn antenna. The circuit board itself serves as the fourth side. Some sections of the metalized plastic also provide shielding for the microwave circuitry. A dozen screws fasten the plastic cover to the circuit board. Photo B shows the detector's RF circuit board and metalized plastic horn.

Removing the cover reveals that the microwave circuitry is actually on a third daughterboard, previously hidden underneath (see Photo C). The tiny dimensions of the etched microstrip lines testify to the very high frequencies involved. There are two SOT packaged transistors and a mixer diode in a "beam-lead" package. The mixer diode is incredibly small—only about 0.01" square! Use great care when handling circuit boards with such minuscule devices.

How It Works (More or Less)

Of course, the radar detector instructions didn't include a schematic or theory of operation. Snooping, just plain guessing, and a spectrum analyzer helped me ascertain how this device worked, and whether it could be useful to the microwave experimenter.

Experience dictates that if this is a superheterodyne receiver, it may well radiate some of its local oscillator('s) energy. And sure enough, it does. I pointed a small X-band horn on the input of the spectrum analyzer (a Hewlett-Packard 8551B with a 8441A pre-selector) at the horn of the radar detector and picked up a weak signal sweeping between 11.4 GHz and 11.6 GHz (see Figure 1). The sweep rate was about 40 hertz, but it turns out that this was not the only local oscillator involved.

If this device is meant to receive signals around 10.525 GHz, then there may well be an IF between 11.4 GHz minus 10.525 GHz, and

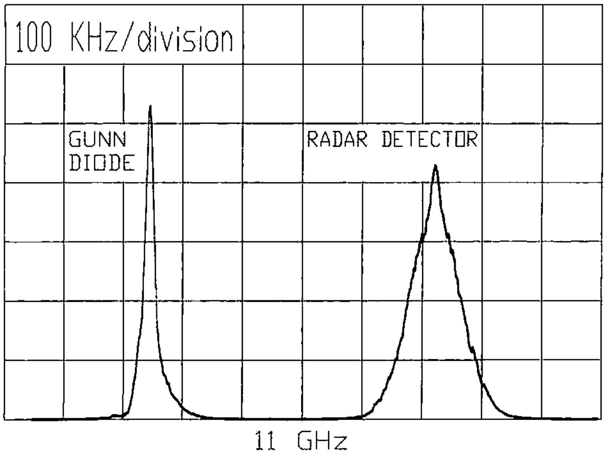

Figure 3. A comparison of the radar detector's VCO stability to that of a Gunn diode oscillator.

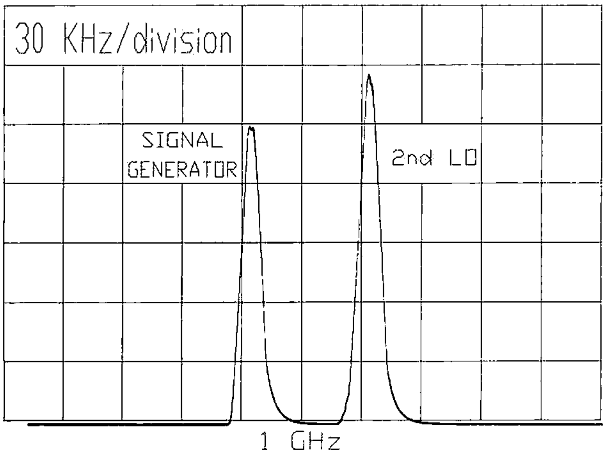

Figure 4. A comparison of the radar detector's second LO stability to that of a signal generator.

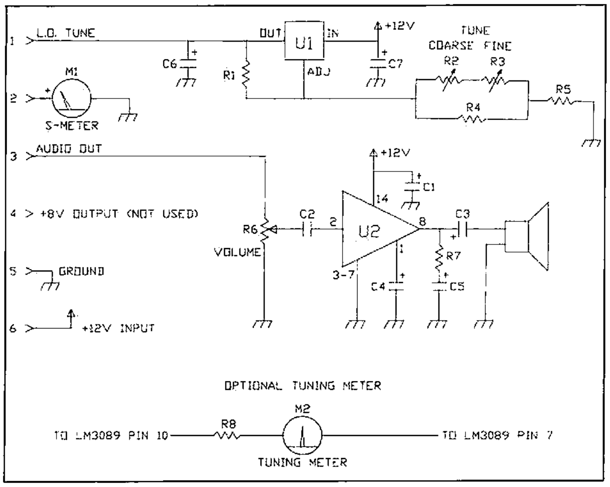

Figure 5. Schematic of the new circuit board.

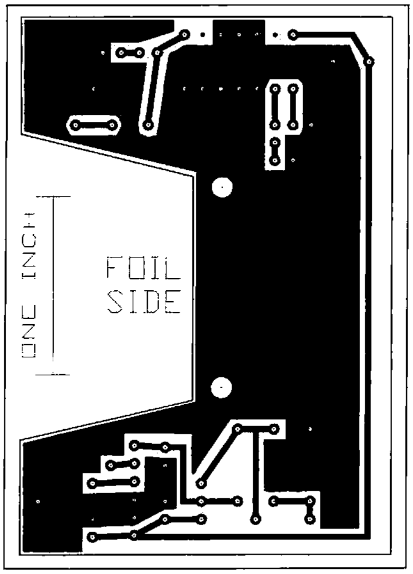

Figure 6. Foil side of the PCB.

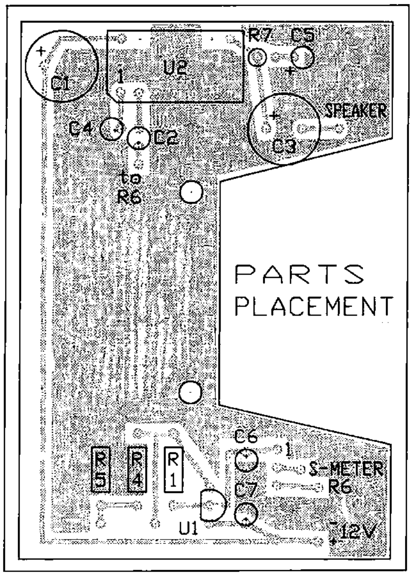

Figure 7. Parts layout.

11.6 GHz minus 10.525 GHz. "Sniffing" around the circuit board with the spectrum analyzer revealed a strong signal at about 1 GHz. This "second LO" signal was not swept in frequency.

Further examination revealed a welcome sight: a standard LM3089 FM Receiver IF System chip! Now here is something familiar with a 10.7 MHz input, an audio output, along with provisions for an S-meter and AFC. The input of the LM3089 is preceded by a 10.7 MHz ceramic filter which in turn is preceded by a couple of what appear to be microwave transistors. The first transistor amplifies the 1 GHz signal from the microwave circuit board and passes it on to the second transistor, which is also fed by the 1 GHz second LO, mixing the received signal down to 10.7 MHz (see Figure 2 and Photo C).

The 1 GHz second local oscillator is a TO-92 packaged transistor, while the first LO is comprised of the two SOT packaged transistors on the microwave daughterboard. This first LO, of course, is actually a VCO (Voltage Controlled Oscillator.)

Actually, the VCO probably generates RF at a lower frequency, the 11 GHz being harmonically generated in the mixer diode. With so many signals, and their possible mixes, it's hard to be sure even with the aid of a spectrum analyzer. The VCO/mixer diode combination also probably generates signals from 22.8 GHz to 23.2 GHz for the reception of K-band speed radars. The sweeping of the first LO frequency is probably done to make sure that any and all signals in the two radar bands are detected, and to make critical RF stage alignment unnecessary. A clever approach.

Modifying the Detector

The presence of the LM3089 FM IF chip hints that the radar detector might be easily adaptable to reception of Amateur Radio Service 10 GHz FM signals, such as those generated by M/A-Com Gunnplexers or Solfan transceivers. Two things still must be done: 1) Stop the first LO from sweeping and make it tunable. 2) Determine if the two LOs have sufficient purity and stability.

It turns out to be quite easy to accomplish the first item. The first LO is powered through one of the pins of the 6-pin connector that connects the RF and controller boards. If that pin is bent so that it doesn't mate with the connector, a variable bench supply can be hooked to it. In my unit, a 3.64 volt DC input made the VCO generate 11.5 GHz, while 5.9 volts yielded 11.0 GHz. The VCO drew only about 1 mA.

To check for purity, I observed the first LO signal on the spectrum analyzer side-by-side with a signal generated by a Gunn diode oscillator tuned a few kHz away. Although a Gunn diode signal might not be considered a paragon of purity, it does provide a valid guide, especially since the radar detector will be receiving Gunn diode signals in its new life. Figure 3 shows the result. The first LO signal on the right is much broader than the Gunn diode signal on the left. This is not good.

Note that the significant "pulling" effect of moving one's hand in front of a Gunn diode

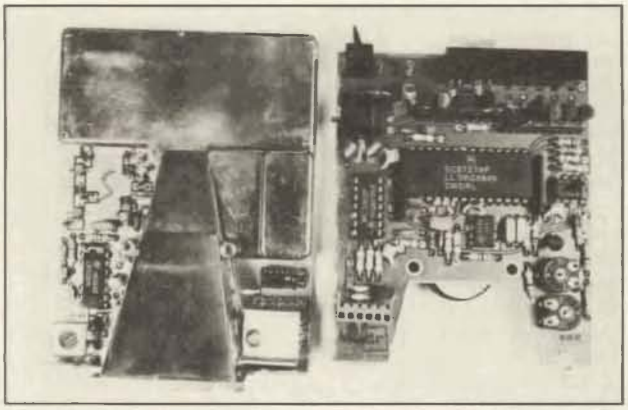

Photo B. Inside the radar detector. RF board on the left. Controller board (not used) on the right.

Photo F. The finished unit with the horn extension installed.

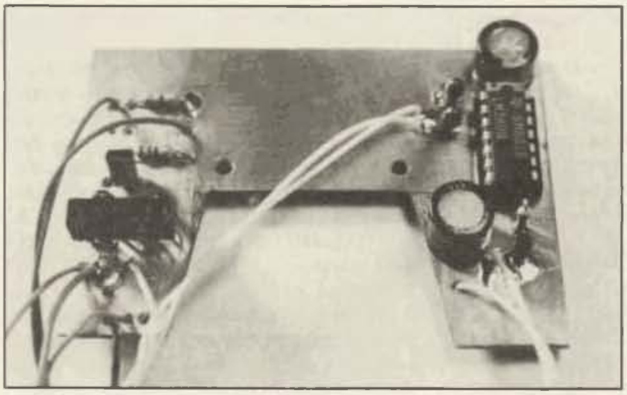

Photo D. The component side of the new printed circuit board.

transmitter horn is absent in the radar detector. The first L.O. is noisy, but reasonably stable.

The 1 GHz second LO signal is much more acceptable. In Figure 4, the 1 GHz LO signal (right) is identical to the signal from a TS-419/U signal generator (left).

At this point we know that the radar detector can receive FM signals due to the presence of the LM3089 IC. Also, it can be tuned to receive in the amateur portion of X-band by powering the VCO used as the first LO with a variable power supply. The question remaining is whether the first LO signal is good enough to receive clear signals from the kinds of transmitters most amateurs presently use on microwave. The easiest check is to just try it.

Checkout

I have had an X-band beacon in continuous operation from a local mountaintop for some 10 years (see my article, "X-band Beacons," in the January 1987 issue of *Ham Radio*). Reception of a familiar, real-world, "known" signal from this beacon would prove the capability of the radar detector.

I rigged up a perfboard circuit with an LM317 variable voltage regulator and an audio amplifier (see Figure 5). This perfboard replaced the detector's controller circuit board. The LM317 circuit used a 10-turn pot for voltage adjustment. This circuit was designed to cover 3.64–5.9 volts, or 11.0 GHz–11.5 GHz, out of the VCO. The audio amplifier, an LM380, was connected to the audio output of the RF board's LM3089. Time for a DXpedition!

At a convenient location near my house, about 10 miles from the beacon, I can get a solid signal. I parked there and just pointed the modified detector through the car window and slowly turned the 10-turn pot—and there was the beacon's MCW ID signal! It wasn't strong, but it was surprisingly stable. And this is using only the radar detector's tiny horn for the antenna. I was sold on the fact that a modified police radar detector should make a great microwave bench-servicing tool and portable field-test receiver.

Further tests performed on the bench revealed that the modified radar detector produced usable audio when receiving signals from my M/A-Com Gunnplexer transceivers. It was also sensitive enough to pick up the 10 GHz calibration signal of a 1N23 diode driven by a 2 meter handheld (see "X-band Calibrator" in the April 1981 issue of *Ham Radio*).

The Final Design

The next step is to tidy up the circuitry, especially the added audio amplifier. Perfboard is not a good medium for high gain amplifiers of any frequency. A printed circuit board's solid groundplane helps keep unwanted oscillations and feedback under control (see Photo D and Figures 6 & 7). Two 10-turn pots with counting dials are very desirable for tuning the VCO. One, R2, serves as coarse tune. The other, R3, is fine tune. R4 and R5 set the range of voltage available. The values shown allow tuning through the entire amateur X-band (10.0 GHz–10.5 GHz).

These values may have to be adjusted to each particular Micro-Eye receiver. Be sure to test the final circuitry before plugging the new circuit board into the radar detector RF circuit board. Note that microphonics, or vibration-induced feedback, may be introduced if the speaker is mounted too close to the molded plastic shield. An S-meter, a zero-center tuning meter, and a frequency meter are optional add-on's.

The new circuit board can use the 6-pin connector that was removed from the unused controller circuit board. The optional zero-center tuning meter wires directly to pins 7 and 10 of the LM3089. The result is a circuit board that plugs into the Micro-Eye RF board, replacing the original controller board.

Packaging is up to you. I found that everything, including a NiCd battery, fit nicely in a 7" x 4" x 3" plastic box (see Photo E).

Parts List

Capacitors, all 16 WVDC or better.	
C1	25 µF electrolytic or tantalum
C2	0.1 µF
C3	100 µF electrolytic or tantalum
C4	4.7 µF electrolytic or tantalum
C5	0.1 µF
C6	1 µF electrolytic or tantalum
C7	1 µF electrolytic or tantalum
Resistors.	
R1	220 ohm ¼-watt fixed
R2	1k 10-turn pot (coarse tune)
R3	100 ohm 10-turn pot (fine tune)
R4	680 ohm ¼-watt fixed
R5	390 ohm ¼-watt fixed
R6	10k pot (volume)
R7	2.3 ohm ¼-watt fixed
Semiconductors.	
U1	LM317L variable voltage regulator
U2	LM380N audio amplifier
Miscellaneous.	
M1	S-meter, 100 µA movement
1	6-pin connector (remove from unused controller circuit board)
2	ten-turn counting dials
1	8 ohm speaker
1	PC board
Note: A blank PC board is available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for $6 + $1.50 shipping/handling.	
Optional, for center-tune meter.	
M2	100 µA zero-center meter
R8	4.7k ¼-watt fixed

Horn Antenna Extender

The Micro-Eye presents a bit of a problem if you want to change the antenna. Its antenna is rather closely integrated into the entire RF board design. You don't have a handy coax connector or waveguide flange to hook things to. Its horn does work quite nicely, and would probably make a satisfactory feed for a 1' to 3' dish.

As an experiment, I made an extension to the integral molded horn, fashioning it from double-sided copper-clad printed circuit board. The extension sleeves inside of the existing horn (see Photo F).

Remember: *You must be very careful not to touch the mixer diode located inside of the horn!*

This extension adds an estimated 8 dB of gain. Field tests verified a marked improvement in signal strength.

You could try modifications I didn't attempt, such as adding an AFC (Automatic Frequency Control), or replacing the horn antenna with an adaptor to a standard waveguide flange or coax connector. The latter modification would allow measurement of the noise figure of the receiver.

The BEL Micro-Eye police speed radar detector is easily modified for reception of the 10 GHz ham band. The cost is low and the performance is quite respectable. This device should serve as a useful accessory for the microwave amateur.

UHF Source Dipper

The easy way to tune circuits from 400–500 MHz!

by Martin Beck WBØESV

Most amateurs who have used or tried to build a 432 MHz dip meter are familiar with the problem of the inductor being so small that it is useless for getting into UHF circuitry. All the so-called solutions I have seen are either clumsy ("I need three hands!") or mechanically unstable. The device described here solves all of these problems, as well as several others. It is small, inexpensive, unusually accurate, and a beginner can build it in four hours.

As the design emerged, I refused to budge from two requirements. The first was that the hairpin inductor be no shorter than 1¼". Second, I wanted a physical layout such that I could look at the tuning dial and, without moving my eyes, see the hairpin loop as it entered the circuitry being dipped. That meant having the loop on one end and the dial on the other. As you can see from Figure 3, this layout is particularly conducive to good UHF wiring techniques, resulting in a very handy little dipper that tunes from 400-500 MHz.

The three figures here show the construction process of the dipper. Note that the holes for the capacitor and extension shaft must line up for smooth tuning, and the brass mounting plate must fit the box you use.

In wiring this circuit, use very short, near zero lead length—this is crucial. (Figure 2 shows a blown-up version with too long lead lengths, simply for clarity.) Cut out and bend the brass plate to fit your box. Then use the actual components (capacitors, resistor, etc.) to aid you in punching the holes for everything. This is the best way to avoid excessive leads around the oscillator circuit.

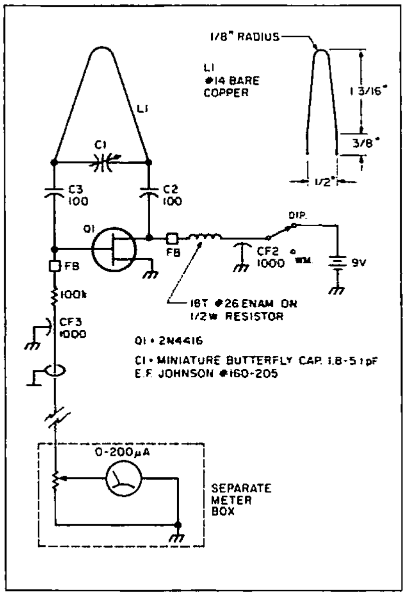

Figure 1. Schematic for the 400–500 MHz source dipper.

I was lucky enough to have an old National Co. ceramic FT-243 crystal socket. Teflon™, phenolic, etc. are OK. Unless you are an experienced VHFer, don't use a metal box. If you do, disaster awaits you! For convenience in replacing the battery, I bought a package of

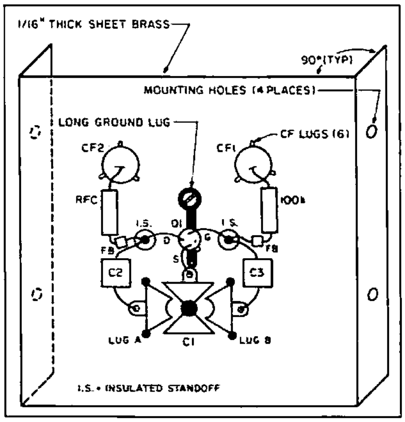

Figure 2. Details of the oscillator mounting plate (not to scale). Lead lengths are shown excessively long for clarity. Very short, near zero leads are mandatory. Note: The two pins on the crystal socket (hairpin coil socket) are soldered directly to lugs A and B. The long ground lug and Q1 source are soldered to the C1 grounding lug. Solder the feedthrough cap shields to the plate.

CF1,CF2	1000 pF feedthrough capacitor	
FB	Ferrite beads (2)	
M1	0–200 µA meter	
BT1	9 volt transistor battery	
SW1	SPDT switch	

Misc. components:
Length of RG-174/U mini-coax. Chassis for meter. 1/16" thick brass sheet.
Short length of #14 bare copper wire. FT-243 style XTAL socket.
*C1 available from Radiokit, P.O. Box 973, Pelham, NH 03076. Phone: (603) 635-2235.

snap-on 9 volt battery clips (with wires) from Radio Shack. Since most commercial or home-brew shaft couplers are ¼" in diameter, and C1 has a slightly smaller shaft, you can use a small piece of brass shim stock to mate the capacitor shaft to the ¼" coupler.

Below and left of the tuning knob is a small hole through which the coax is passed to the external meter. I used RG-174/U because it is limp and does not fight you as you move the dipper around.

Now, about calibration. You will be in the ballpark if you match my construction. However, it would only take a few minutes with a 500 MHz frequency counter. The dipper is totally portable so that you can take it to the counter. At any rate, it should be calibrated with reasonable accuracy initially. My unit holds its calibration exceedingly well. The range is shifted by lengthening or shortening L1. No other adjustment exists or is needed.

Since the wavemeter position is used in "hot" circuits, a piece of snug-fitting insulating tubing must be used over L1. I first used heat-shrink tubing, and then scrounged around for an appropriate size of Teflon tubing to go over it. It makes sense to use some other, safer device if you insist on measurements around high-voltage circuits!

Once you have this dipper built and calibrated, you will find it invaluable as a time-saver when making any sort of 400–500 MHz tank circuits. With no AC source required, it can be taken and used anywhere. Battery drain is only a few mils, so replacing the battery is a rare event.

This is the handiest, most accurate 432 dipper I have seen. Along with my UHF field strength meter (in this issue), it allows me to zip painlessly through my 432 projects. 73

Contact Martin Beck WB0ESV at 1637 Hood, Wichita KS 67203.

UHF Field Strength Meter

For 400 to 500 MHz.

by Martin Beck WB0ESV

This field strength meter will cover 400 to 500 MHz. I chose the tank components from several trial units, with the result that when tuning across an RF source within the design range, a very sharp upward kick of the meter occurs. Response is excellent at the design frequency, and extremely poor to nonexistent for nearby frequencies. If light coupling is used, the off frequency rejection is even better. The coupling is accomplished through a 1- to 2-foot length of RG-174/U mini coax, with a phono plug on one side and a small wire loop on the other.

Since we often deal with very weak 400-500 MHz energy, I have included a simple DC amplifier to drive the meter. The amplifier employs one transistor, with a potentiometer to vary its gain.

I calibrated my unit with my dip meter and a digital frequency counter of known accuracy. In a field strength meter (FSM) one should not expect frequency meter accuracy, but this one, with care in construction and calibration, can easily exceed what is generally necessary.

The schematic, drawings, and photos show all that is needed to build this device. Wiring associated directly with the tank circuit should emulate good VHF construction practices, use very short or near zero lead lengths.

Once your unit is completed and calibrated, you will find yourself being reassured that LO output really *is* on 404 MHz. For those who have no facilities for close calibration, the little 400-500 MHz dipper in this issue will do a good enough job for all but the most stringent situations. I "never really needed" a good 400-500 MHz FSM until I had one! I believe you will enjoy its help as much as I do. This FSM and its mate, the UHF source dipper (also in this issue) form a powerful pair that belongs on every VHF workbench. 73

Martin Beck WB0ESV, 1637 Hood, Wichita KS 67203.

Great Ideas From Our Readers

Ending Transmit Chatter

Transmit "chatter" can be quite annoying on both repeaters and links. Most repeaters have a certain "hang time" where the transmitter stays keyed up after the input signal is lost. For home-brewed links and simpler repeaters that don't have these tail-timers, weak signals barely breaking a receiver's squelch can cause an annoying popping, as the link's (or repeater's) transmitter keeps toggling on and off. Here's a simple cure for that problem.

The 14538 monostable multivibrator (here wired in leading-edge trigger, retriggerable mode) gets triggered on the rising edge of the PTT's release. This generates a one-second pulse, during which time the signal will either return, or the circuit will drop out. Through the 4071, either a valid PTT signal or an output from the 14538 must be present to keep a transmitter toggled on. The duty cycle of the 14538 can be calculated by T = RC (T in seconds, R in ohms, C in farads). (See Figure 1a.) Remember to tie all unused inputs of a gate to the proper logic level. (See Figure 1b.)

When releasing the transmitter from transmit mode, the output of the 4071 is positive. Depending on the type of circuitry in your transmitter, this may be unacceptable, or you may wish to use a transistor buffer to protect your IC. If this is the case, I recommend substituting a 14001 for a 14071, as per Figure 1c. (The pinout of the 14001 is identical to the pinout of the 14071.)

Klaus Spies WB9YBM, Niles IL

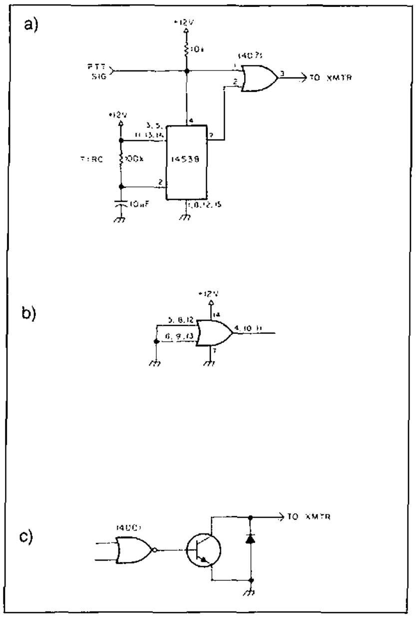

Figure 1.

Adding Digital Output to a Signal Generator

Many experimenters, being on a limited budget, often keep older equipment instead of buying newer equipment with more capability. Because of this, many of them are still using signal generators that do not have digital output capability. Modifying a sine-wave oscillator to give the digital output used in today's modern technology is much easier than most people may think.

Most modern waveform generators provide two digital signals, the second being basically the inverse of the first. The following circuit provides these two outputs, and has one major advantage. While most modern waveform generators provide only one output jack, this circuit, when properly enclosed in its own box, can have two output jacks, one for each signal polarity. The circuit is centered around the MC14093 (CD4093) integrated circuit. This IC is used primarily as a Schmitt trigger. (In this particular IC, the Schmitt trigger is in the form of a NAND gate.) Since the first Schmitt trigger inverts the incoming waveform as a by-product of its operation, another invert function must be provided to have the output signal (labeled "square-wave output") come out at the same phase as the input signal. There are four Schmitt trigger NAND gates available, so there is no problem using a spare gate as an inverter.

Schmitt triggers are used to "square up" noisy square-wave signals, and to take sine waves and convert them to square waves over their hysteresis curve. Note that the input (sine) wave must be symmetrical, and have no DC offset voltage, or the duty cycle of the output square wave will be affected. (This might be desirable in some experiments, but for basic circuits this should not be a major concern.) Reminder: It is always good engineering practice to tie the inputs of unused gates to an appropriate (high or low) logic level.

Let's consider IC output. For driving a typical circuit built by an experimenter, little else is required on the outputs of the 4093, except possibly a 100 ohm resistor between the output of the '93 and the "outside world." This will protect the IC from overcurrent should the output inadvertently be connected to a high voltage, or be shorted to ground. If you expect that the '93 will have to drive several ICs at one time, or if for some other reason you expect a higher load, I strongly recommend that you use a 2N2222A transistor as a buffer/driver.

Another consideration is a housing for the IC. While a single IC can be mounted on almost anything (no critical or special circuit board is required), remember that all power leads should be suitably filtered to ensure pure DC. They should also be bypassed to get rid of any high-frequency noise caused by such things as a high generator frequency, and (for all of those doing work with radios) to bypass any RF from getting into the circuitry. This shielding includes putting the IC into a metal box, and **GROUNDING THE BOX TO THE POWER SUPPLY GROUND**—don't leave it floating!

The 14093, being a CMOS IC, can accept up to 18 volts for supply, with the input signals not to exceed the supply voltage (regardless of which supply voltage you decide to use). This capability can provide another feature for our circuit. A simple switch can toggle in a 5 volt supply to the IC when a 5 volt maximum output is required while experimenting with TTL components. Or, a switch can be toggled to provide 12 volt levels when working on CMOS ICs or other 12 volt circuits (like those found in many mobile radios).

With this circuit, we have now not only brought old (nondigital) signal generators up to modern capability levels, we have also surpassed the capabilities of some of the lower-priced modern generators.

Klaus Spies WB9YBM, Niles IL

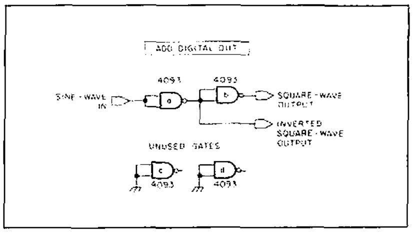

Figure 2.

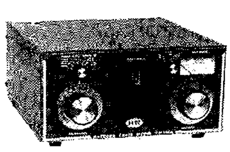
ANTENNA TUNERS

1500W.



MODEL VS1500A ANTENNA COUPLER

The Barker & Williamson VS1500A antenna coupler is designed to match virtually any receiver, transmitter or transceiver in the 160 to 10 meter range (1.8 to 30 MHz) with up to 1500 watts RF power to almost any antenna, including dipoles, inverted vees, verticals, mobile whips, beams, random wires and others, fed by coax cable, balanced lines or a single wire. A 1:4 balun is built-in for connection to balanced lines.

FEATURES INCLUDE:
- Series parallel capacitor connection for greater harmonic attenuation.
- In-circuit wattmeter for continuous monitoring.
- Vernier tuning for easy adjustment.

Front panel switching allows rapid selection of antennas, or to an external dummy load, or permits bypassing the tuner.

Dimension (Approx.): 11" wide x 13" deep x 6" high

Weight: 6 1/2 lbs.

Price: **$499.00** SHIPPING & HANDLING $4.00 — FOB Factory. Fully warranted for one year.

MODEL VS-300A ANTENNA TUNER

GUARANTEED THE BEST VALUE YOU'LL EVER FIND!

$111.00 SHIPPING AND HANDLING $3.50

- FULL COVERAGE - 1.8 - 30 MHz
- HANDLES UP TO 300 WATTS
- MATCHES VIRTUALLY ALL ANTENNAS
  DIPOLE — BEAM
  INVERTED VEE — RANDOM WIRE
  VERTICAL — MOBILE WHIP
- ACCEPTS COAX BALANCED LINE OR SINGLE WIRE FEEDLINE
- BUILT-IN ANTENNA SWITCH
- BUILT-IN WATTMETER WITH FORWARD AND REFLECTED POWER FOR SWR MEASUREMENTS
- WATTMETER ACTIVE EVEN WITH TUNER IN BYPASS POSITION
- ATTRACTIVE CHARCOAL GRAY FINISH AT HOME IN ANY HAM SHACK
- RUGGED 4:1 BALUN FOR BALANCED FEEDLINE

73 Review

by David Cassidy N1GPH

The Kenwood TH-27A

A mini HT with maxi features.

Kenwood U.S.A. Corporation
P.O. Box 22745
2201 E. Dominguez St.
Long Beach CA 90801-5745
Tel. (213) 639-4200.
Price Class: $420.

I got my first glimpse of Kenwood's latest entry into the micro-HT arena last September at the Southwest Convention in San Diego. Still awaiting FCC type acceptance, the rig was loaded with a dead battery by the careful Kenwood reps. We couldn't even play with it! Needless to say, this was a tantalizing first look at what has finally come to market as the Kenwood TH-27A.

First Impressions

The first thing you ask yourself upon seeing this little rig is, "Where's the battery?" Unlike most HTs, the battery pack does not hang off the bottom of the unit. Nor is it inside, like the internal battery in ICOM's mini IC-2SAT. The battery pack slides neatly and solidly *into* the bottom of the unit's case, where it disappears from view. The battery, a standard 7.2 volt 700 mAh type, provides about two hours of life at high power (1 minute xmit/3 minute receive ratio). If you leave the power set on low, you should see nearly four hours of operation.

Speaking of power, instead of the usual "High/Low" power choice, the TH-27A offers four choices: HIGH, MEDIUM, LOW, and ECONOMIC LOW. The HIGH setting will give you 5 watts with a 12-volt source and 2.5 watts with the 7.2-volt battery. MEDIUM power provides 2 watts, LOW power provides ½ watt, and ECONOMIC LOW gives 20 mW. The manual states that you'll get about 15 hours of battery life if you leave the power on ECONOMIC LOW. I suppose that would be enough juice to get around a fairground or short parade route.

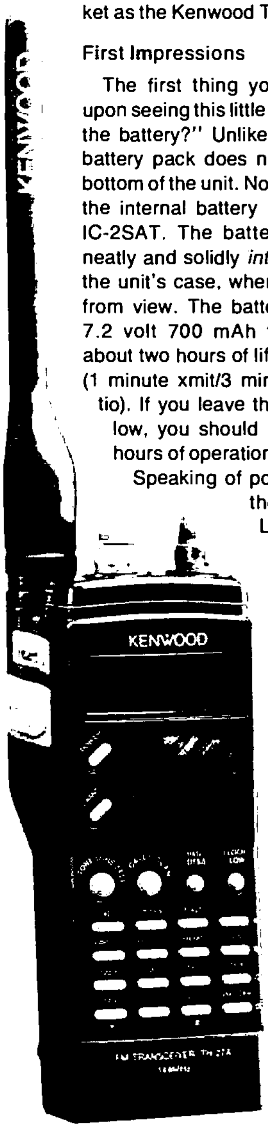

Photo. The Kenwood TH-27A—all curves and full features.

For the past several years HTs have been getting more and more complicated, with more and more features. With the TH-27A, I think we have finally reached the saturation point. This is the first HT that I actually had to read the instruction manual for before operating it. Once you understand the procedures, they're no more difficult than any other modern HT, but the sequences are not readily apparent. Alas, I fear that this will become the norm, as every manufacturer will now want to include all the available features in their products.

The unit is turned on by a front panel button, as opposed to the standard volume control knob. The power button must be depressed for 0.3 seconds for the unit to be activated. I have to say, this seems like something that was designed into the unit for the sake of being different. I can't think of any reason why the standard volume control switch wouldn't be preferable. In fact, although the button is recessed somewhat from the rest of the case, it wouldn't take much for the radio to be turned on by accident. This happened to me when I packed the TH-27A in my suitcase the night before a trip. The only thing that saved me from finding a dead battery was the automatic power-off feature, which turns the radio off after one hour of inactivity.

This little radio feels very solid in your hand. It is obvious that Kenwood has put a lot of thought and design time into the ergonomics of this rig. Every corner and angle is rounded, with no sharp edges. The entire radio is shaped in a very slight "V" angle which fits the curve of your palm and makes the PTT switch fall right under your finger, whether you're a lefty or a righty. The thin and flexible rubber ducky antenna has a covering that comes over the BNC connector and sits flush with the radio housing. This adds much to the sleek appearance of the unit, but it means that there is a definite front and back to the antenna. You can attach it any way you choose, but it is obvious that the antenna and radio were designed to look good a certain way.

The top of the radio holds the volume, squelch and tuning knobs, as well as the speaker, microphone, and DC jacks. All other functions, including the LCD display, are on the front of the rig. This means that there is nothing on the back except the belt clip. This is a trend that I hope continues in HT design. I have always found it downright aggravating to have to hunt for switches or buttons on the back of an HT, especially if you're like me and always keep your HT in a protective case. In addition to the standard 16-button keypad, there are four round buttons which control various functions, as well as the power and lamp buttons. All buttons (except power and lamp) control multiple functions. You won't damage anything by simply experimenting with the different buttons, but this is one radio that forces you to refer to the manual.

The LCD display shows a complete picture of your operating parameters. . .and, I do mean complete! There are 26 separate symbols that inform you of every possible setting. As in most HTs, the display must be read from below or straight on, but even then I found the display a bit on the dark side. The plastic window lies flush with the radio housing. In fact, it is slightly convex. This adds to the physical beauty of the radio but does nothing to protect the window from scratches. Two green LEDs provide illumination. A push of the button will light the display, which will stay lit for five seconds after the last key operation. You can have constant illumination by first pressing the function key.

The speaker audio is surprisingly good for a radio of this size, and the transmit audio is what we've come to expect from Kenwood. Some people prefer transmit audio that boosts the high end, feeling that it increases the communications quality, but I find it tiresome to listen to for any length of time. After all, this is FM. There's no QRM to cut through, and if you're in a noisy environment you're going to have to use an earphone (or hold the radio to your ear) anyway. Kenwood's audio is more evenly balanced and I've always found it easier to listen to.

Frequency Management

Most HTs are placed into either VFO or MEMORY mode by the push of a button. The TH-27A is unique in that MEMORY mode is always available at the push of a single button. It took some time to get used to, but once I became comfortable with the system I found it very convenient.

To access the VFO, you press the ENTER key. This blanks the frequency display and allows you to directly enter a frequency with the numeric keypad. You may now tune the VFO with the tuning knob, or repeat the proce-

dure (first hitting the ENTER key) to directly enter another frequency. Hitting a numeric key without first hitting ENTER will immediately choose the memory channel of that number. Once you are in memory, the tuning control will change the memory channels, or you can simply hit another numeric key to access a different memory channel.

This procedure confused me at first, mostly because I was trying to stick to my "never read a manual first" philosophy. A quick read of the appropriate page in the manual made everything clear. For the next few days I would still try to enter a frequency without first hitting that ENTER key, immediately accessing the appropriate memory channel, but in time I became comfortable with the procedure.

You may also return to the VFO from memory by simply hitting the numeric key for the memory channel you are currently in. For example, if you are currently in memory channel 5, touching the 5 key will immediately transfer you back to the VFO. This feature would be very handy for public service or emergency operation, where net control was on a local repeater but on-sight and other communications were on another repeater or simplex frequency. No need to remember what memory channel holds the secondary frequency. Simply put it into the VFO and you can switch instantly between the two.

Thanks for the Memories

There are 40 memory channels and three ways to access them—single number, two number, or tuning knob. With single number entry, you can immediately access memory channels 1–9 by touching the appropriate number key. Channels 11–40 can then be accessed by turning the tuning knob. In two-number entry, all memory channels may be accessed by the number keys, but a 0 must be entered before channels 1–9. Since I travel around the country quite a bit, I found this way of managing memories very convenient. I simply leave the local repeaters in memory channels 1–9 and set the access to single number. When traveling, I enter the new frequencies into the higher memory channels and switch to two-number control. Upon returning home, it's back to one-number access until the next trip.

Memory channel 1 also serves as the priority channel. With the priority alert function on, the radio will sound a tone to let you know when there is activity on that frequency. If you choose, you can set the priority function to immediately switch to the priority frequency, but I think most would opt for the alert tone only.

There is also an independent call channel memory, accessible by a touch of the CALL button. Many hams like to keep their home repeater or local simplex calling frequency in this position. The immediate entry also lends itself to public service work, as mentioned earlier.

Scanning Around

The TH-27A has seven scanning options and three scanning modes. The scanning options are:

Band Scan—which scans over the entire band.

Programmable (PROG-1, PROG-2) Band Scan, 1 and 2—two user-programmable scanning ranges.

MHz Scan—scans over a 1 MHz range.

Memory Scan—scans through all memory channels that have data stored in them and that have not been locked out.

VFO/Memory Scan—alternate scanning of the VFO and the last used memory channel.

Call/VFO Scan—alternate scanning of the VFO and the CALL channel.

Call/Memory Scan—alternate scanning of the CALL channel and the last used memory channel.

In addition to all this, there are three scanning modes. SEEK scan will stop on a busy channel. CARRIER scan will stop on a busy channel, but resume scanning two seconds after the carrier drops. TIME scan stops on a busy channel for five seconds, then resumes scanning even if a signal is still present.

Features, Features and More Features

The TH-27A has the full boat of features we've come to expect in our HTs. Although there is not enough room in a short review to discuss them all (the manual is a full 51 pages), a few of the highlights include:

Tone Squelch/CTCSS. Subaudible tones are programmable and may be used in transmit (to access repeaters) and/or in receive. When used as a tone squelch, your HT remains silent unless the correct tone is present. This is very convenient for monitoring a busy repeater or a simplex frequency at a hamfest. You and your friends decide on a tone to use and you won't have to listen to everyone else's communications. The tone encoder is standard equipment on all TH-27A's sold in the U.S. and Canada. I hope the days of paying extra for this feature are over.

DTMF Memory. Up to 10 telephone numbers of up to 15 digits each may be stored in memory. Call up your repeater's phone patch, push a button, and you're all set. The tones are played through the HT's speaker while being broadcast. It may be totally psychological, but I like to hear the tones (my old Kenwood TH-25 doesn't do this, and it has always bugged me).

Dual Tone Squelch System. This feature keeps your squelch on until the proper three-digit code is heard. This is similar to the tone squelch, except that it's activated by regular tones instead of subaudible tones. This would be handy if any of your friends don't have subaudible tones.

Paging. There is a "Dual Tone Multi Frequency" paging system, the explanation of which takes up six pages in the manual! Basically, it allows you to store your own paging code, and those of other individuals or groups, into memory. This allows you to silently monitor a frequency, until one of the group pages you. The manual doesn't do a very good job at explaining this rather complicated system.

Clock. The TH-27A may be set to display a 24 hour clock.

Timer. In addition to the regular "power off" feature (the transceiver shuts down after 59 minutes of inactivity), you may set a "power on" and "power off" time in conjunction with the 24-hour clock. Just set the time of your local VHF net, and your TH-27A will turn itself on at that time. You can also set it to shut itself off.

Pros

This little rig has a lot going for it. Some of the things I really like are:

Overall design. The TH-27A is a beautiful radio. Kenwood ought to submit it to the Metropolitan Museum.

Overall quality. This is as solid a radio as you're going to find. A lot of the solid feel has to do with the unique battery arrangement. The battery slips up into the transceiver with a nice solid "click." The rubberized knobs and buttons feel very secure.

PTT switch. You may think this is really picking nits, but many of Kenwood's previous HTs had PTT switches that were hard to push. Try spending a day wrestling with the PTT switch on the TH-25, and you'll start to appreciate a smooth and light PTT switch. The PTT switch on the TH-27A is easy to operate, even after several hours.

Included features. The TH-27A has a plug for direct 12-volt input. The subaudible tone encoder is also standard. It's about time these two features became standard on all HTs.

Power settings. The choice of four power settings allows for maximum battery life.

Cons

Nothing in this world is perfect. Some of the things that bugged me about this radio are:

Power switch—it's too easy to turn the radio on or off by accident. The standard volume control switch would have eliminated this problem.

Non-recessed LCD display. It looks great, but I bet every TH-27A we ever see will have scratches across the display window.

One-way antenna. Again, it looks great, but couldn't it have been designed without the front and back sides different?

Manual. The manual for the TH-27A is full of those grammatical errors that at best make for comical reading, and at worst make for confusion and frustration. Kenwood's manuals are generally pretty good, so I don't know what happened with this one. I hope they'll consider rewriting it.

Final Comments

I really think Kenwood has a winner in the TH-27A. The high quality is evident as soon as you hold it in your hand, and the 7.2 volt 700 mAh standard battery is nice to have in such a small HT. The small size makes it easy to pack away for trips, or carry on your belt all day. There's also a 440 MHz version (the TH-47A) for those who need it.

If you're currently shopping for a new HT, I would strongly suggest taking this mini for a test drive. 73

Future Modulation Amateur Television

Sometimes called frequency modulation.

by Don C. Miller W9NTP

How would you like to forget problems of sync clipping and nonlinear power-limited amplifiers? Amateur television enthusiasts today have the opportunity to free themselves from many of the problems that have plagued them for the last thirty years. Gone is the need for line samplers used to adjust sync, white and blanking levels after the signal has passed through the stages of amplification. The video signal may be improved by 20 to 30 dB over the conventionally transmitted AM television signal. Amateurs reading this article may wonder how they could have missed these great improvements in ATV transmission.

The truth is that amateurs in general did not miss the advantages of frequency modulation (FM) ATV. Only the American hams have missed it. By traveling around the world visiting ATV hams, I have found that FM ATV is used exclusively by European and other foreign ATV enthusiasts. Hams recognized the advantages early on but, since spectrum space was not available on the 70cm band, it wasn't until activity on the 1200 MHz band became popular that it really started to grow in Europe. The lack of available equipment became a problem. If amplitude modulation had been considered, the problems would have been even worse. Semiconductors are notorious for their nonlinearity so the possibility of operating them in Class C mode became the first real advantage of FM ATV in getting some power on the air. In case the reader does not understand the difference between linear amplifiers running at near half power and class C amplifiers running at full power, consider the following.

In amplitude modulation, the modulating waveform is asymmetrical. The video signal is a wide bandwidth signal which is combined with a vertical and horizontal sync signal. The waveform becomes asymmetrical with the sync signal in one direction (maximum power) and the video signal in the opposite direction. The peak power always refers to the power of the sync. In an amplitude system, when nonlinear amplifiers are used the sync signals may be compressed by operating the amplifiers with too much average power output. The Bird wattmeter may read higher when overdriving the amplifier, but a line sampler in the antenna lead will show that the sync pulse has been greatly reduced in height.

With FM ATV, since the sync pulse is modulated in an FM mode, the amplitude of the transmitted signal is constant. The amplifier can be operated at maximum power for as long as the transistors can survive. This is a distinct advantage at UHF, where it is so hard to maintain high power and still have a good waveform. This is the reason that the FM repeaters on two meters and other VHF/UHF bands use voice FM. Single sideband would be more efficient if it were not required to have linear amplifiers, like amplitude modulated television.

Some examples of the use of FM TV are found in commercial and military fields. Today we see satellite dishes in backyards. These antennas are directed toward satellites that broadcast high quality commercial TV. They all use FM for their video transmission. When you see a local TV broadcast station do a remote from a site where action is taking place, they use FM TV. The military use FM TV on all of their television guided missiles. This leads one to believe that there must be something superior for the FM mode over the AM mode.

I feel that amateur radio has existed over the last fifty years only because of its technical contributions. Amateurs experiment and develop new modes and equipment that later show up in commercial use. They also give Third World countries an opportunity to have a free source of electronic and communication technicians that these countries would not be able to afford otherwise. FM ATV affords an opportunity to experiment and build equipment to test out new bands for propagation and other unknown results.

I have always been critical of ATV in America because hams chose to use techniques and circuits that were designed in 1940. Costs were a factor, and equipment discards from commercial usage made it possible to have a lot of fun, but it does not advance the state of the art. A glaring example is the continuous use of the NTSC method of sending color on ATV. If you examine modern methods of sending color you will find that almost any other method is better. When high definition television (HDTV) becomes a reality you will find that a system called Multiple Analog Components (MAC) may be used. This is a system where a single line of TV is divided into two or three parts. Part of the line is the color signal and the other part is luminance, or black and white signal. Slow scanners have been using this method of sending color for 10 years. Why not try it on ATV?

How do you get started in FM ATV? First, you should read the literature. The British

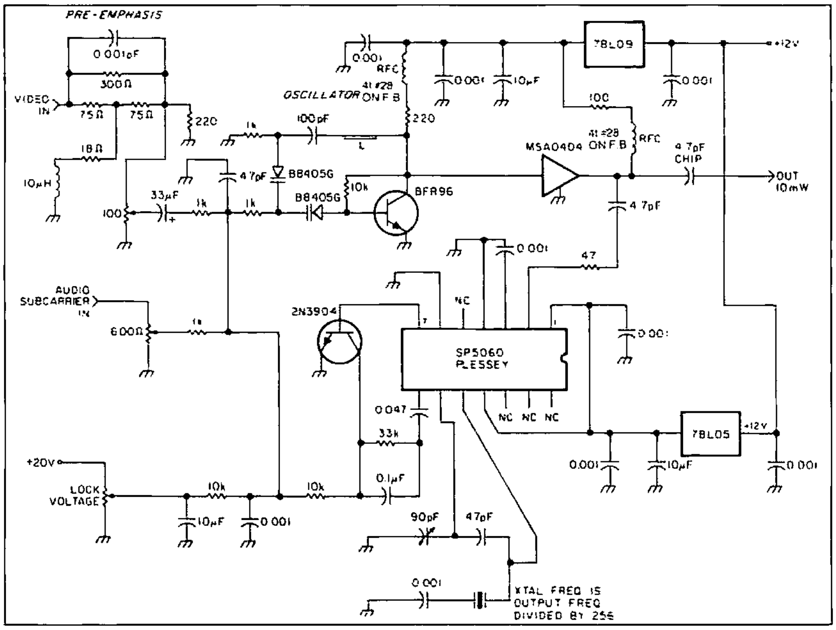

Figure 1. Basic circuit used to produce FM-ATV on 23cm. (Modified from a circuit from the January 89 issue of VHF Communications, p.25).

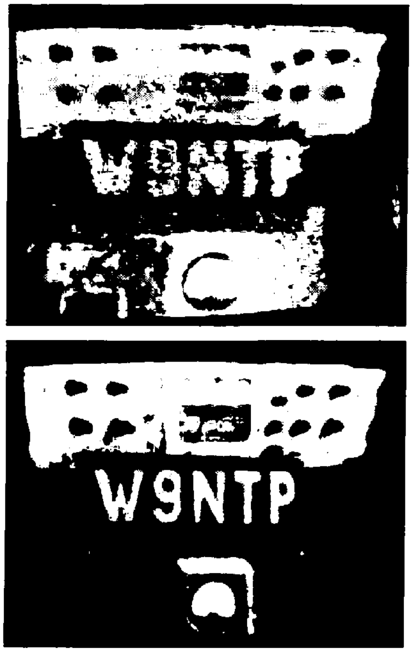

Photos A & B. Comparison of AM & FM ATV. Top photo is that of a 1 watt 1255 MHz AM ATV transmission over a lossy path. The bottom photo shows the result of using FM modulation over the same path. Note the increased picture quality.

Amateur Television Club magazine is a wealth of information both for circuits and equipment kits. A second magazine called *VHF Communications* from Germany, printed in English, publishes circuits and sells kits for building your own system (kits are available for all circuits). If you are interested in a very good theoretical article on the comparison between AM and FM ATV, I refer you to *VHF Communications*, March, 1986. If you are unable to find this issue, send me a green stamp for a copy.

Since good circuitry for FM ATV is hard to obtain at low cost, many of the first circuits were free-running oscillators that were varied in frequency by a varactor diode modulator. The most popular one that has been produced hundreds of times around the world is called the "Solent." The Worthington group of the BATC still sells this kit. Recently it has been updated by locking it to a crystal oscillator.

Some of the highest quality FM ATV units built today come from a British company called Wood Douglas. Their modules are very well made and are crystal-locked so that you don't have to chase the signal around the band. With FM ATV, signal drift is not serious because of the nature of detection and bandwidth. Wood Douglas makes transmitter modules (10 milliwatts output) and 1200 MHz downconverters which convert to their IF FM ATV board, giving output video and audio. The amateur only needs to connect the output to a computer monitor and he is ready to receive video and audio.

With the British pound increasing even more and the desire of Wood Douglas to discontinue their amateur radio line, Wyman Research developed a new unit which has proven to be superior in design to the original Wood Douglas exciter, and at a much lower price.

A British company called Plessey has developed a chip that is unique to the semiconductor world. This chip is phase-locked-looped and has a divider chain that inputs a 1200 MHz signal at a rather low level, divides it by 256 and locks it to a crystal in the 4 MHz range. The loop is adjusted by varying the voltage on a varactor diode to bring the free-running oscillator into range. Once the loop is locked to the crystal, video and audio subcarriers can be added to the loop control voltage to vary the frequency to produce FM ATV which is locked to the carrier frequency. The circuit is extremely easy to get going and is the basis of most of the FM ATV systems around the world. Included in the circuitry is a preemphasis circuit, standard to all FM ATV, which increases the deviation at high video frequencies. This is later compensated for by using deemphasis at the receiver to restore the proper levels (see Figure 1). *[Ed. Note: A PC board or kit is available for this transmitter. See address at end of the article.]*

A word about FM ATV receivers: Those of you who are flea market buyers may want to try discarded satellite receivers. Caution is in order. Satellite receivers are designed for larger bandwidths and deviation than is used on amateur FM ATV. The result is that there is increased noise in the received signal because of the added noise in the unused passband, and the level of the video is much less than normal because of the lack of full discriminator detection. A real experimenter should be able to decrease the bandwidth and add a stage of video gain to make them usable. Don't judge the results of FM ATV by using a satellite receiver. A receiver designed specifically for FM ATV will do remarkably better.

Note that I've said nothing about using a TV set in an FM ATV system. After all, we have been talking about Future Modulation (FM) not Ancient Modulation (AM). If you insist, however, an ordinary TV set can detect an FM ATV signal poorly by using the principle of slope detection.

Those of you who have trouble building AM video transmitters should have no trouble building FM video transmitters. After all, most of the complicated circuitry has been eliminated.

I would enjoy receiving comments in regard to FM ATV. The cost per watt for FM ATV is now lower than AM ATV. Considering the fact that no expensive test equipment is required to build the gear or align it makes it a very good mode from an economic viewpoint. 73

Subscriptions to the BATC as well as a line of FM ATV equipment are available from Don C. Miller W9NTP at Wyman Research, Box 95 RR 1, Waldron IN 46182. Phone: (317) 525-6452.

Take A West Indies DXpedition?

"No Problem, Mon!"

by "Dee" Logan VP2E/W1HEO

Can three Ohio couples combine a vacation and DXpedition to the West Indies, rack up 4,273 QSOs in five days, plus avoid serious sunburns? As they say on Anguilla, "No problem, mon!"

The idea for our DXpedition to Anguilla originated with several members of the Lake County (Ohio) Amateur Radio Association. All shared the fantasy of someday finding themselves in a rare DX location, being pursued by the multitudes and working the pileups. As exciting as that idea was, we broadened its appeal by combining it with a family vacation.

Our casual talk turned serious when several club members and their spouses began meeting over potluck dinners to plan the real thing. First, what was our criteria? We decided on a somewhat rare DX country that had reciprocal licensing with the United States, was in a warm vacation spot served by commercial airlines, and had affordable lodging that allowed ham radio operations.

Selecting the Location

Each of us agreed to research one or two possible spots. For several weeks we collected information, with the Caribbean a favorite area. Our short list included Montserrat, the Bahamas, Virgin Islands, Anguilla, and the Turks and Caicos.

After completing our individual research, we reassembled to make our selection. There were several attractive possibilities. Some hams rent Caribbean vacation retreats that are completely equipped with ham radio stations. However, we felt that since these were widely advertised, they would tend to be well-occupied and thus less rare.

Anguilla was especially interesting to me. If you want good information on a DX country, ask someone who lives there. I ran across VP2EHF on 20 meters one day and quickly plunged into a detailed discussion with Dave about Anguilla. He said that there really weren't many hams on his island—perhaps six. This was good news. It sounded to me like a somewhat under-represented country on the air and thus a good candidate.

Anguilla, I learned, is the northernmost of the British Leeward Islands. It lies some 150 miles east of Puerto Rico, just seven miles from St. Martin. A small island, it's only 16 miles long and three miles wide. Its long, serpentine shape was noted by Columbus, who sailed by in 1493 and dubbed it Anguilla, the Italian word for eel.

Unlike some Caribbean islands that offer exotic scenery such as mountains or rain forests, Anguilla is rather plain. The 35-square-mile country is flat, rising only 213 feet above sea level. It's also dry. There are no streams, rivers or waterfalls, and most of

Photo A. The VP2EOH DXpedition's main operating location—a seaside villa on Anguilla. Note the 15-foot tower and tribander on the roof. The flat roof made antenna installation easy.

Photo B. The tower for VP2EOH was borrowed from an Anguilla ham, and the tribander was donated to the island's Boy Scouts afterwards.

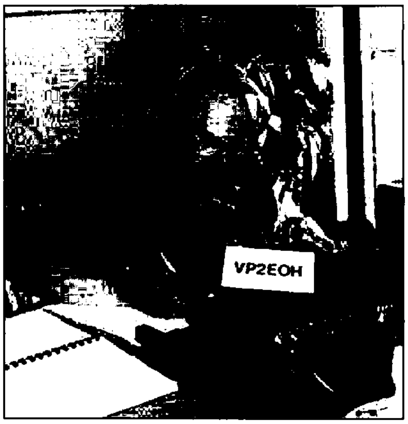

Photo C. VP2EOH, operated by Dee, W1HEO, on Anguilla during April 1990.

Photo D. On a beach on Sea Feathers Bay, across from the operating site, VP2EOH expresses satisfaction with the DXpedition results.

the vegetation is low-lying grasses and cactus.

For seekers of glitter and nightlife, Anguilla is definitely not Las Vegas. It is quiet, calm, and has no cities at all. While there are a few exotic, pricey resorts on the island, for the most part Anguilla is residential, with a few shops and markets scattered here and there.

So why visit the place? The answer is found on its sparkling white beaches. There are 30 of them, along with colorful coral stretches offering some of the world's best scuba diving and snorkeling.

For a ham, the island is ideal. No mountains block your signal. Easy licensing: Show your U.S. ticket and pay a $38 U.S. fee. Electrical supply is 115 volts, 60 Hz alternating current. Nights are quiet, with little manmade interference.

Additional details on VP2E came in a comprehensive DXer's guide published by the Anguilla Amateur Radio Association. (Available from P.O. Box DX, The Valley, Anguilla B.W.I.) Anyone planning a DXpedition there should write for this handy reference.

We selected Anguilla on its many merits. Certainly one of them was that it was an undeveloped island that wasn't overrun with either tourists or hams.

Getting Ready

A remaining task was finding a place to stay. Our prime requirement was a hotel or villa that welcomed hams. Several candidates were identified by Scott KO8O. The off-season rates began in mid-April, and we found some neat villas available then on the south side of the island at Sea Feathers Bay. And they welcomed hams!

Now for the deposits and reservations. Which of the group would go? Three couples decided to make the trip: Bob K8BL and his XYL Marcia; Scott KO8O and wife Jo; and myself, "Dee" W1HEO, and spouse Liz. We all dug deeply into our credit cards and took the plunge.

In the months leading up to our trip we pulled together the radio gear. We all agreed that to assure a good signal we'd run a yagi. Fortunately, we found a small triband beam at a sale price. It was assembled, checked out for low SWR, and then shipped to Anguilla well ahead of our departure date. (We donated the beam to the Anguilla Boy Scouts after our DXpedition.) We also carried along a 40-meter inverted vee, but opted not to operate on 75 meters, figuring there would be enough activity on 10-40 meters. We were right! We took an ICOM 735 transceiver and borrowed a power supply from a VP2E ham. We decided against bringing an amplifier. It would be too heavy, and we doubted that we'd need it. Right again!

On a cold, snowy morning on April 18, 1990, we began our trip. A great day to fly south to the sun! Our flight took us to San Juan, Puerto Rico, with several hours between planes for sightseeing. We headed for old San Juan, with one of our main stops the El Morro Castle, a large fortress rising 140 feet above the sea. After some shopping and a bite, we left on the last leg of our flight, arriving in Anguilla after dark. It had been a long day.

We awakened to our first day on Anguilla with a glowing sun and sparkling cobalt waters of the Caribbean outside our villas. That's what we came for. Another was the ham license. We headed for the offices of Radio Anguilla and presented ourselves to the official in charge, Nat Hodge. He wrote our simple, one-page licenses, collected $38 U.S., and also issued us a special callsign, VP2EOH. Since we qualified by operating in a contest—the North American QSO Party—we picked EOH for Eastern Ohio Hams.

Setting Up and Getting On

Getting the station together was next. We had borrowed a 15-foot aluminum tower to support our tribander, but discovered to our surprise that it was still in the box! So, around 1:00 p.m. we began the complex assembly job. We worked in what little shade we could find, since the sun was high and so was the humidity. Even natives complained about the heat. The tower was a problem. It didn't go together right. We tore it apart. We rebuilt it. Three times! Finally, we settled for a reasonable approximation of its intended design, ignoring the parts left over.

Since the villas we rented had flat roofs, it was easy to erect the tower and beam and hang the inverted vee from the top, dropping the ends off each side of the villa. Then came a problem. As we checked out the rotor and plugged in the transceiver, the rig died! While it worked in the FM mode, it was going nowhere on SSB. Bob K8BL tore the unit apart, searching for a clue. Murphy had struck again!

After puzzling over the rig for some time, Bob grabbed his voltmeter and checked some things. Bingo! The coax feedline to the antenna showed 70 volts AC. No wonder the rig was tripping out. We unplugged the rotor control and the stray voltage disappeared. While we had no idea why the problem existed, we decided to simply leave the rotor unplugged and apply power only with the rig off the air. At last we were ready to send our brand new VP2EOH call letters to waiting DXers!

We began by checking 10 meters. We were in luck! The band was hopping, with signals pouring in from stateside. Our first call

brought an instant response from one of our fellow radio club members, Mark KB8FKM, who had obviously been camped out on frequency waiting for us to show up. Signal reports were good, so obviously we were doing well with our 100 watts. The salt water assist was dramatically evident.

And the pile-ups! While we realized that VP2E was somewhat in demand, we didn't realize what the sound of that demand would be at our end. It sounded like buzzing bees, with no calls heard. We quickly decided that if we were to achieve an efficient rate of contacts, we would have to maintain discipline on frequency and use a system to pick out the calls.

Our system was to go by call areas whenever the pile-ups got bad and, when necessary, to make up short lists based upon the last two letters of a call. We tried to give our QSL route, location, name and other info about every five minutes or so. We also thanked people for being patient while we worked as fast as we could. In fact, most operators—especially the stateside DXers—are to be congratulated for their on-the-air discipline.

For five days we kept VP2EOH on the air about 18 hours daily. We alternated operating, eventually settling on a two-hours-on, four-hours-off cycle. Two hours of intense operating in the tropical heat was about the right span. After that, it was time to hit the beach or go sightseeing.

While checking out the island in our rental car, we drove carefully on the left side of the road, stopping at shops, restaurants, craft galleries and various beaches. Snorkeling and scuba diving were excellent. Our villas provided us with a great view of St. Martin nearby, so we naturally took the 20-minute ferry ride over for a look. French restaurants abound, so we sampled some of the cuisine at lunch. It was outstanding! Later, we discovered the 2 meter repeater on the island and used it to contact locals VP2EOH and VP2EE.

Our experience with big pile-ups showed the value of asking for just the last two letters of a call. Doing this cut down the size of the pile by 60%. After making contact, the first thing someone working a DX station should do is *transmit their call* and make sure it's copied correctly by the DX station. Also, don't waste time during a contact asking for routine info such as QSL routes. These items are usually given about every five minutes or so, as we did.

Despite the time out for sightseeing, we worked 4,273 stations in the five days we were on the air. Our log showed 87 countries, 50 states, and all continents. About 57% of our contacts were stateside, with 81% on SSB and 19% on CW. The lion's share of QSOs were on 10 meters (2,838), followed by 15 and 20 meters with 686 each. We averaged slightly over one contact per minute. Conditions were very good, with openings to North America and Europe well into the evening hours.

Planning Your Own DXpedition

We hope you worked VP2EOH. And we invite you to plan *your* DXpedition. It's great fun, and doesn't cost much more than a regular vacation to the same spot. *Being* DX is a great experience. Take it from one who's done it, it's the vacation of a lifetime! Many details must be covered in advance, of course, so plan early to insure a smooth DX operation.

We learned a few other things in the process that may interest DXers.

First, *time your calls*. During big pile-ups, it's tough to pick out calls, so wait a few seconds before transmitting your call. We found that often the tail-ender was the only one we copied.

Next, *listen to the DXer's pattern*. Is each contact just call and report? Or is the DXer collecting QTHs and names? Note what's going on before transmitting. Full calls or last two letters? ■

SHF Systems Linear Transverters for 1240 and 2304 MHz

Down East Microwave
Box 2310, RR1
Troy ME 04987
(207) 948-3741
Price Class: $140-$310

Explore the microwave bands with these easy-to-build kits.

One of the biggest obstacles to increasing the amateur population on our microwave bands has been, and continues to be, the lack of ready-made equipment at reasonable prices. Several manufacturers have offered a line of linear transmit and receive converters (known as transverters) that are ready to run out of the box, but at prices that may discourage newcomers.

For those with the technical know-how, the best method has been to "roll your own" equipment, either completely from scratch or from a kit. If you have access to microwave test equipment, this process isn't all that difficult. For those who don't, and who possess only a basic knowledge of microwave operation, it can be an uphill battle all the way with all of the precise assembly and alignment involved!

Things have changed considerably with the advent of microwave monolithic integrated circuits (MMICs) over the past few years. These devices offer broadbanded, no-tune performance with reasonable gain and noise figures at affordable prices. MMICs can be used both as low-power RF gain stages and as RF amplifiers on receive, and they are reasonably stable in operation.

SHF Systems has introduced a line of linear transverters which make extensive use of these devices, along with etched microstrip circuitry. As a result, even the basic kit builder can be up and running on several microwave bands with a minimum of test equipment and time. *[Ed. Note: Down East Microwave is the sole distributor of the SHF Systems kits.]*

The SHF Transverters

Currently, SHF Systems offers transverters for 902 MHz, 1296 MHz, 2304 MHz, and 3456 MHz. In each case, the complete transverter consists of a local oscillator (LO), transmit upconverter, and receive downconverter. All three are located on one PC board on the 902 MHz version. The other three use a separate LO board. Our review versions (SHF-1240 and SHF-2304) are very similar in operation and appearance, although the SHF-2304 transverter board is smaller in size. Both use the same LO circuit, with different crystal frequencies, and both systems use an intermediate frequency (IF) of 144 MHz, making them a natural for use with 2 meter multimode equipment, and even 2 meter FM transceivers.

The key to a stable microwave signal is a stable local oscillator. The SHF-LO employs a 2-stage circuit of BFX89 devices, functioning as a crystal oscillator and buffer amplifier. A series of MMICs and one HP2835 diode multiply the signal into the 540-580 MHz range. Two 3-stage bandpass filters and one low-pass filter ensure a clean signal at the output. An option allows the user 4 dBm more gain (required for the 2304 input).

For 1296 operation, the LO signal is doubled by another HP2835 diode into two more MMICs and associated filters, resulting in an LO injection frequency of 1152 MHz. Both 144 MHz IF ports are coupled to a pair of Wilkenson splitters in a "rat race" mixer scheme. At 2304 MHz, operation is similar except that the 4th harmonic of the LO is selected (2160 MHz) and filtered before injection into the Wilkenson splitter.

Actual TX and RX mixing is performed by a pair of HP2835 diodes on the SHF 1240, while a tiny diode pack of HP-HSMS2822 diodes do the trick at 2304. In either case, there are no tuning adjustments to be made, only some careful soldering when installing these diodes. These mixers are quite sensitive, as only 1 mW of energy at 144 MHz is required for drive.

Both boards are completely symmetrical. This means that either side of the board can be used as a receive or transmit converter, or that both sides could be used for the same purpose. As in the LO, no tuning adjustments are necessary. Depending on the model, different MMICs are used as TX and RX gain stages with 3-pole bandpass filters between the cascaded gain stages.

Although the noise figure performance of the MMICs used is quite good, a GaAsFET preamplifier on the RX side will yield noticeable improvement. Typical power output on both boards is in the range of 10 mW, but higher outputs can be obtained with more drive and LO injection. The RX conversion gain is typically 20-25 dB, more than enough to drive the front end of a 2 meter multimode transceiver.

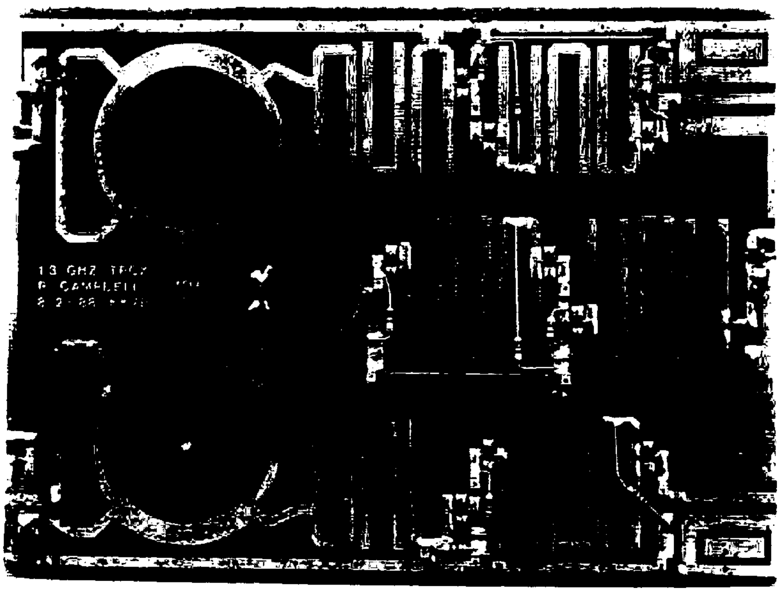

Photo A. The SHF-1240 transverter board (1296 MHz).

Construction

The manual for the SHF LO states that it can be built in under two hours. I took just about two hours to be extra careful, since the case lead identification on the various MMICs can be confusing. For the record, large case MMICS (such as MSA-0404 types) have a dot on the OUTPUT lead, and smaller MMICs (such as the MSA-0685) have it on the INPUT lead. Most cases of trouble with these kits are a result of incorrect lead positioning.

You won't need much test equipment to

check the LO. A simple VOM will do, as you peak the crystal trimmer for current. This will typically be in the range of 200 mA, and a distinct peak will be observed. A 600 MHz or higher frequency counter is handy to verify the actual output frequency while you make this adjustment. An RF millivoltmeter can be used to measure actual LO levels, or a diode probe and FETVOM will suffice for relative output.

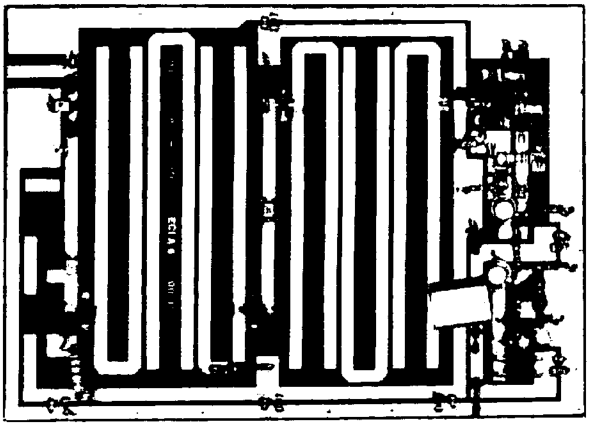

Photo B. The SHF-LO board.

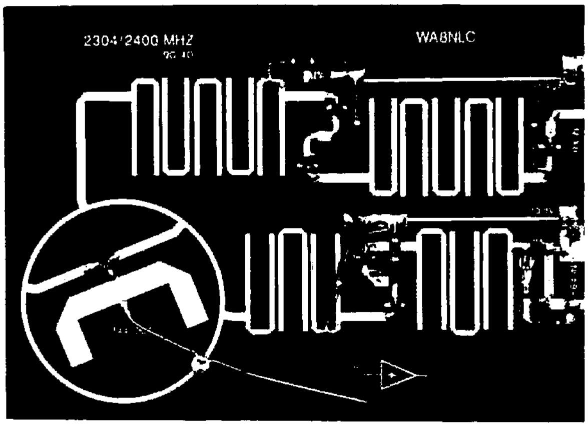

Photo C. SHF 2401K receive converter (for mode S receive).

The transverter boards present varying levels of difficulty. The SHF 1240 version is assembled on G10 epoxy board and can be done in about one hour. The SHF 2304 uses Rogers Duroid material, and all of the grounding holes for each MMIC must be soldered from the top to the bottom ground plane, using copper foil supplied in the kit. This adds about 30 minutes to an hour to the job.

MMIC installation is simple. I suggest cutting the leads prior to soldering, and watch those case dots! Once the MMICs are soldered in, they are very difficult to remove without destroying them. Fortunately, they are also relatively inexpensive ($2–$6, depending on the model), so you won't break the bank if you goof up.

Testing the transverter boards may require nothing more than a sensitive frequency counter on transmit, and another 2304 MHz signal source on receive. Since there's no tuning to be done, the units will either work fine or they won't work at all when powered up! The input power level of 1 mW may be problematic, so the distributor (Down East Microwave) offers a PIN-diode IF switch and attenuator kit as an accessory. This kit can handle up to 3 watts of 144 MHz energy, depending on the resistors installed.

Performance

Both transverters have worked very well here and in portable operations. I soldered the LO to the back of the SHF 1240 board and installed the combination in a Radio Shack metal housing (CAT# 270-272), using BNC connectors for 1296 RX and TX connections as well as 144 MHz In/Out. This chassis also accommodates the PIN diode board. The addition of a Down East 1296 preamplifier and RF power module completes the station, giving me 6 watts output in a small package.

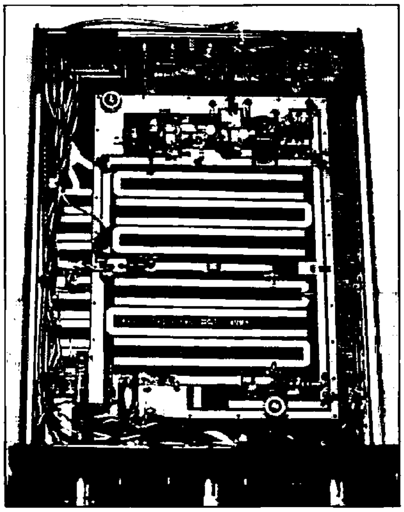

Photo D. The SHF 1240 complete transverter.

The 2304 MHz station was installed in an enclosure sold by Down East Microwave. Again, the LO was soldered to the back of the transverter board. Since this combination is much smaller, I was able to fit it and the PIN diode board into this enclosure. SMA connectors were used at the 2304 RX and TX connections, with a BNC at 144 MHz. Down East sells an inexpensive 2304 GaAsFET preamplifier kit using an Avantek ATF10135 device which was also added. A pair of Frontier Microwave gain stages brought the output up to 2 watts.

I've used the 1296 station twice from mountaintops and it has been extremely reliable over a range of battery voltages, working down into the 11.5 volt level without difficulty. Although the PIN diode board offers a MMIC IF post-amplifier stage as an option, I found it to be unnecessary when used with a Yaesu FT-290RII transceiver. Due to tolerances in the LO crystal used, however, my actual 1296 frequency was off by about −8 kHz from what was displayed.

On 2304, the displayed frequency was much closer, reading low by 5 kHz. Since the 2 watt gain block needs 24 VDC, I use a dual power supply system in the base station. A surplus Microwave Associates 24 VDC SMA relay is also powered by this system. When portable, I use only the first gain stage which needs 12 VDC and develops about 300 mW output, more than enough power when mountaintopping with a 45 element loop yagi.

Other Observations

I can honestly say that these are the easiest microwave kits I've ever assembled. They both worked right off the bat, although the 2304 MHz unit exhibited some instability in the MSA0885 TX output stage. This is due to a downgrading by Avantek of this device from "unconditionally stable" to "conditionally stable" at this frequency. Repositioning a resistor lead to function as a choke cured the problem.

As with any microwave equipment, you'll be working with some very small components, especially the chip capacitors and diode packs. I suggest using a well-lit work area and placing sheets of white typewriter paper under the components to locate them quickly. Doubling over a strip of masking tape on paper and sticking the parts to it until needed works very well.

The documentation for these kits is constantly being upgraded. For 1296, it rates a B+, and is suitable for the builder with basic kit-building experience. Having a knowledgeable ham friend is a plus. For 2304, I give the documentation a C− as it had several errors on a hand-drawn pictorial diagram and showed two resistors connected to the wrong leads on MMICs. Unlike the 1296 kit, no schematics are shown.

Bill Olson of Down East Microwave has made every effort to ensure that buyers of these kits get the correct information when questions do arise—even to the extent of shipping some extra parts gratis, so "factory support" rates an A+. Thanks, Bill!

To summarize, both kits represent a low-cost, low-risk way to become active on microwave frequencies. And you'll have the added benefit of learning a few things about microstrip and surface-mount construction techniques along the way.

The SHF-1240 complete kit, including TX/RX converter and LO board, is priced at $139; the assembled board is $179; the transverter in an enclosure with a PIN diode IF switch is $225. The SHF-2304 complete kit, including TX/RX converter and LO board, is $195; the assembled board $235; complete transverter in an enclosure with a PIN diode IF switch is $310. 73

Hams with Class

Carole Perry WB2MGP

Staten Island NY 10313-0006

Lights, Camera, ATV

One of the fun things about being an instructor of an amateur radio class is that you can never run out of exciting and informative demonstrations to bring into the classroom. The "sparkle" component (see the October 1990 "Hams with Class") of your program is what will have your students remembering the course years after they've completed it.

Since many youngsters today are overstimulated and underworked, they've got to be approached with something of obvious benefit to them right off the bat. Remember always that the way the instructor presents the posed to amateur radio in a fun way.

When the big day came, we weren't disappointed. John WA2QYX, Mike KB2EQQ, Danny N2EHN, Lee WA2JWR, and 12-year-old Walter KB2IOZ provided us with an outstanding experience. John, Mike, and Danny interacted with the children in a thoroughly professional and well-coordinated manner. Their own obvious enjoyment and expertise with this media came through loud and clear. Even passersby on the street were impressed with the way the event was being handled. Lee and Walter worked behind the scenes to make sure everything went smoothly.

The children not only learned about how enjoyable ATV can be, but also about how terrific it is that hams can rely on each other for help, resources, and fun.

Photo A. John, Dan, and Mike setting up the van with ATV equipment for the demo at I.S. #72 in Staten Island, New York.

topic is of critical importance. Children are the best at reacting to a teacher's sense of excitement. If you are genuinely enthusiastic about your presentation, you'll have them at complete attention, anticipating something special. Don't disappoint them. Hit them right up front with what's in it for them.

Recently, I set the stage for a demonstration of amateur TV at my school. The children in my 6th, 7th, and 8th grade ham radio classes have often heard members of the Bayonne Emergency Management Amateur Radio Club on the air discussing ATV. They were looking forward to the morning when my fellow club members would be arriving to set up an ATV demonstration in our school auditorium.

Plenty of Participation

Filled with anticipation, my students quickly spread the word to their other schoolmates and teachers. Before I knew it, I had several requests from other staff members to bring their classes to the auditorium to see the demonstration. Of course, I arranged for the additional seating and enjoyed the idea of non-ham students being ex-

John and Mike KB2GVJ, his son, submitted the following write-up to me. Mike is 14 years-old, and he has been a ham for two years. He loves going along with his dad and the others whenever he can to help demonstrate ATV.

John Anzivino WA2QYX's Report

A television appearance can bring out the "ham" in all of us. Imagine what fun it was to let a group of 6th, 7th, and 8th grade students get into the action. On October 15 several members of the Bayonne Emergency Management Amateur Radio Club, BEMARC, demonstrated the ATV mode of amateur radio to the students of Staten Island Intermediate School #72. Six club members participated in the live TV demo, complete with a fully equipped mobile van and a small downconverter connected to a large-screen TV set in the school auditorium.

Preparation began early in the morning, when John WA2QYX, Mike KB2EQQ, and Danny N2EHN met for coffee near the school. The other two club participants, Lee WA2JWR and his 12-year-old son, Walter KB2IOZ, met them at the school at 8 a.m. The camera equipment, a basic camcorder, was set on a tripod in front of the school. The antenna was a simple 440 MHz vertical. The output of the camcorder was fed into a small 10-watt ATV transmitter, and we were ready to go! A mobile 440 MHz vertical antenna was connected to the downconverter inside the school auditorium, and the output was displayed on the school's large-screen TV set.

Photo B. Mike KB2EQQ stands at the back of the class to watch the ATV demonstration from the viewpoint of the kids.

As the students watched live TV pictures transmitted via amateur radio, the club members explained how easy it is to have fun with your own TV station. Imagine sharing live television pictures all summer long with your friends all over town; doing homework together on two-way television; sharing videotapes of your vacation; showing each other your gifts during the holiday vacation; or putting your parents, brothers, sisters, and the family pet on your own TV show!

During the demonstration, several people walking by on the street were put on television. Most stopped to say hello to the students, and all were impressed with the idea of personal television. The next step was to put some teachers on the screen. We asked one teacher, who teaches a drama class, to come outside and become a star on amateur television. She saw an immediate advantage in ATV for her students. Perhaps we have another prospective ham at I.S. #72.

Finally, we took several students outside and made them ATV stars. The creativity of the students came out in full force. A group of three students said hello to their classmates and told us what they would do with their own amateur TV station. Among the second group of student ATV stars was a budding comic who made the auditorium laugh with his antics and funny faces. When the bell rang, signaling the end of the class period, many students were disappointed; they wanted more ATV action. After the demonstration, many students asked for information on how to get their own amateur radio license. Their teachers explained the school program, and the members of BEMARC promised to return for another television event.

When the BEMARC mobile TV crew arrives at a club meeting site, we usually park the van in a nearby parking lot or other interesting location. If possible, we park on a busy local street and capture people shopping and the colorful scenes in the small store windows. Mike KB2EQQ sets up inside the club.

Photo C. One of the children couldn't resist the opportunity to "ham it up" on TV

He shows all the equipment used for ATV, and removes the covers on the units to explain the function of each board.

We use HTs on simplex for audio between the mobile van and the club meeting room. This way, any club member who has a question for the outside crew can see the mobile member answering over the TV. Full duplex is possible in that manner.

The demonstration starts with the video tape transmitted from the camcorder in the mobile van. Next we switch to live action and show all the outdoor scenes in the area. Before we complete our demonstration, we usually ask some of the club members to come outside and we transmit their picture back to the club.

Since December 1989, our club has completed 14 demonstrations. We've received many comments about our ATV activity, and several more hams have purchased ATV equipment in our area.

If your club is located in the New York City/Northern New Jersey area, and you would like the BEMARC ATV road show, contact our club president, Mike KB2EQQ.

A Coming Attraction

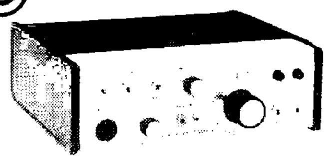
Any instructor who is searching for an innovative and exciting demonstration for the classroom should consider an ATV event. Most schools and clubs today have access to standard video equipment. A basic ATV station consists simply of an ATV transceiver, an antenna, a TV camcorder, a monitor, and a VCR. If you don't have the equipment yourself right now, you can make your desire for a presentation be known to your local radio clubs. Some ham will know of another ham who is involved in ATV. You'll probably be delighted with the response you get. I know you'll be delighted with the reaction you'll get from your audience of students. Amateur TV is a fun way to motivate prospective hams and to capture people's attention.

As a result of the wonderful presentation at our school, five more students had their programs changed so that they could be in the ham radio class. I certainly became convinced of the value of adding ATV to my curriculum. Only a few weeks after the initial ATV demo, our school is well on its way to having its own TV station. Thanks to the generosity of AEA and Mike Lamb, and the help of local hams, we expect to be on the air, seen as well as heard, very soon.

Give it a try and let me know what results you get. ■

AMATEUR TELEVISION

SMILE! YOU'RE ON TV



Only $329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

Pour an Antenna for X-Band

20–20 vision for your microwave system!

by John M. Franke WA4WDL

Ever heard of anyone pouring an antenna? This idea isn't as silly as it sounds, and it's quite easy.

What I am referring to is casting lenses—microwave lenses. It turns out that optical lenses above 3 GHz actually help correct aberrations in the wavefront coming out of a horn antenna, thereby reducing sidelobes. A lens collects and collimates the energy coming out of the horn which results in an increase in gain.

Some time ago, Bill Hoisington K1CLL described a simple X-band (10 GHz) crystal set using a 1N23 detector and a hemisphere of wax as the antenna. (See "The World of X-Band" by Bill Hoisington K1CLL, *73*, March 1975.) He cast ordinary kitchen paraffin to make several short focal length lenses about 0.64cm and 12.7cm in diameter. Paraffin is not optically transparent, but microwaves do not know that. The wax is very clear to microwave energy. Also, the lens surface does not have to be optically smooth. As long as the imperfections are less than an eighth wavelength (0.142 inches), there should not be any noticeable effects. Lenses are much more tolerant of surface errors than are reflector or "dish" antennas. A surface error on a reflector is doubled upon reflection. For example, a tenth-wave bump or dent produces a fifth-wave distortion in the wavefront. A microwave lens with an index of refraction of 1.5 and having a tenth-wave bump or dent produces a wavefront distortion of one-tenth times 1.5 minus 1, or one twentieth wave. In other words, the distortion is less than the physical defect.

Designing and Building the Lens

I can't go into detailed lens design, but I can relate some personal experience in casting lenses. After all, most of us started in microwaves by using dish or horn antennas we found through surplus sales or hamfests. Then, as special needs arose, we designed and constructed custom antennas. The majority of dish and horn antennas used by amateurs fall into the found or purchased category. Few of us actually build them. I have built a couple of special purpose dishes, but will opt for an already-built one any chance I get—I'm basically lazy. (See "The Amazing Cylindrabola" by John M. Franke WA4WDL, *73*, September 1983.)

Several years ago I came across a large glass lens at an antique flea market. I've been keeping it for use as an optical receiver antenna. It is 6 inches in diameter, about 1½ inches thick, and quite heavy. It has a focal length of about 6 inches. The lens is flat on one surface and convex on the other, so it is known as a "planoconvex." Such a large fat lens is poor for optical imaging, but it's a great light collector. However, I needed two antennas. So, I decided to try to cast epoxy resin replicas of the glass lens.

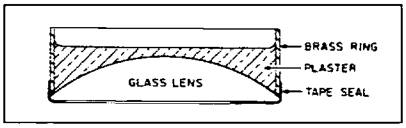

Figure 1. Forming the plaster mold.

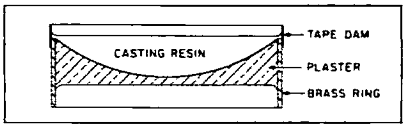

Figure 2. Casting the replica lens.

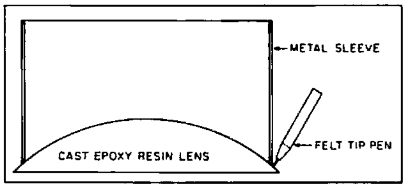

Figure 3. Marking the cast lens for edging. Note that the marking sleeve or cylinder must be perpendicular to this rear surface of the lens.

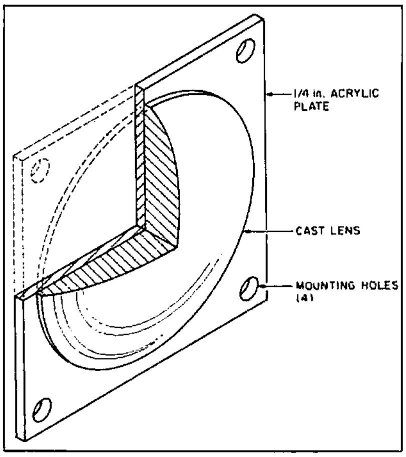

Figure 4. Cast lens epoxied to acrylic support plate.

In my junk box I found a couple of brass rings 6 inches in diameter and 2 inches tall. If I had not had the rings, I could have made suitable rings or sleeves by forming strips of aluminum flashing into a band and taping it to hold its shape. I placed the glass lens on the first ring, curved surface down, then taped the glass to the metal edge with plastic electrical tape, forming a watertight seal. (See Figure 1.)

Next, I mixed plaster, poured it into the mold, and let it harden for several hours. (See Figure 2.) Once the plaster had hardened, I removed the tape, separated the glass lens from the first ring, and taped it to the second ring. Then I poured the second mold and let it harden. (I let both plaster castings dry thoroughly for two days before doing any more work.)

In Photo A you can see several screws protruding through the sides of the brass rings into the plaster. The screws are there to plug existing threaded holes in the rings. They have no other real function, but they may be helpful in holding the ring and plaster mold together.

Once the plaster had dried, it was time to cast the lenses. One mold would have been sufficient, but I wanted to mix the epoxy resin only once. So, I made two molds to have added assurance against having to throw out the mixed resin if I dropped or chipped a mold after the resin was mixed. I placed the molds on a level surface with their smooth cast surfaces up. (If the molds are not level, the rear surfaces of the lenses will be wedged.) A strip of plastic electrical tape was used to form a straight wall lip at the top of each mold. I mixed the hobby casting resin using the least amount of catalyst recommended. This lengthens the curing time, but reduces the

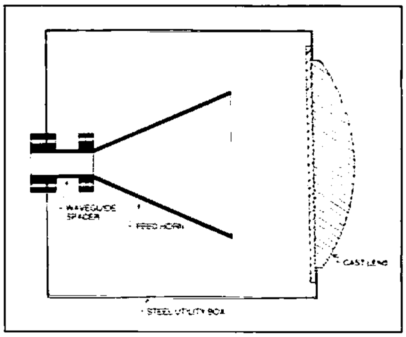

Figure 5. Completed antenna mounted in a 6-inch cube utility box.

chances of uneven curing and cracking due to rapid heat buildup. Next, I poured the resin and allowed it to cure overnight. The curing site should be outside to eliminate any problems with the smelly fumes.

The next day, I separated the cast lenses from their molds. The molds survived and could be used again. The edges of the lenses were rough and chipped, so I decided to trim or "edge" the lenses. I used a cylinder with an outside diameter of 5 inches—the hood from an old oscilloscope—to mark the lenses. (See Figure 3.) The actual edging was done with a disk sander and only took a couple of minutes for each lens. After the edging, the next task was to mount the lenses. Normally, lenses are mounted in a finely-machined barrel with a threaded retaining ring. I can operate a lathe and chase threads, but let's be reasonable! Instead, I epoxied a 5½-inch-square piece of ¼-inch acrylic to the flat surface of each of the epoxy lenses. (See Figure 4.) Then I drilled four mounting holes in each acrylic square.

Light sanding of each lens, followed by a couple of coats of clear acrylic spray, finished the lenses. The sanding is for two reasons. First, although the lenses are of poor optical quality, they can still produce a very hot spot when aimed at the sun, unless their surfaces receive a ground scattering finish. Second, they look better with an even, frosted appearance.

Testing the Lens

One nice thing about small aperture microwave antennas is that you can set up a test range in a short distance. For example, with a small horn source antenna and the cast lenses, a distance of 20 feet is more than adequate. For a source, I used a surplus 2K25 klystron that had its cavity stretched to operate on 10.4 GHz. (See "A Complete X-Band Transmitter" by Stirling M. Olberg W1SNN, *73*, August 1978.) People may shun vacuum tubes, but I can only respect a tube that, like me, is over 40 years old and still working. Besides, have you priced a Gunn diode lately? I would very much like to hear from anyone with a supply of Solfan Gunn diode units. Anyway, the 2K25 puts out about 25mW when used with an old surplus klystron power supply that I got at a hamfest many years ago. The receiving portion of my antenna range is a 0–40 dB attenuator and a tunable detector mount. For metering, I now use a circuit published by Chuck Houghton WB6IGP. (See "Microwave Test Equipment for 10 GHz" by Chuck L. Houghton WB6IGP, *73*, October 1988) I did have to reverse the polarity of the detector diode to get it to work, probably due to a misprint. His circuit is very compact and very sensitive. You cannot go wrong reading his many articles, and he now has a superb column, "Above and Beyond," in *73* every month.

I placed a standard gain horn on both the transmitter source and the receiving setup, and tuned the detector mount for maximum response. Then I set the S-meter to midscale by adjusting the variable attenuator. The attenuator setting at this point became my reference reading. Substituting other antennas on the receiver setup, the attenuator is changed to maintain a midscale meter deflection. The reference reading is subtracted from the new setting. The result is added to the gain of the reference antenna to yield the gain of the new antenna.

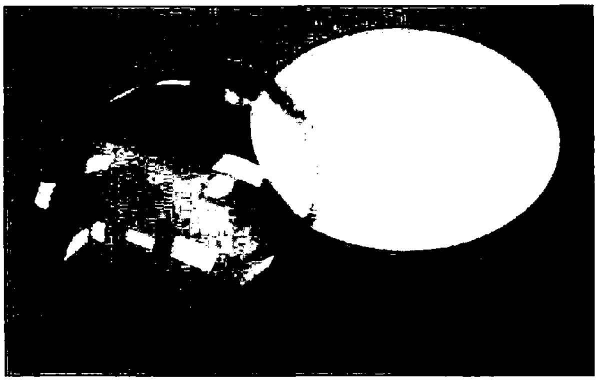

Photo A. Original glass lens and plaster mold.

Photo B. Cast lens epoxied to acrylic plate and lens mounting plate.

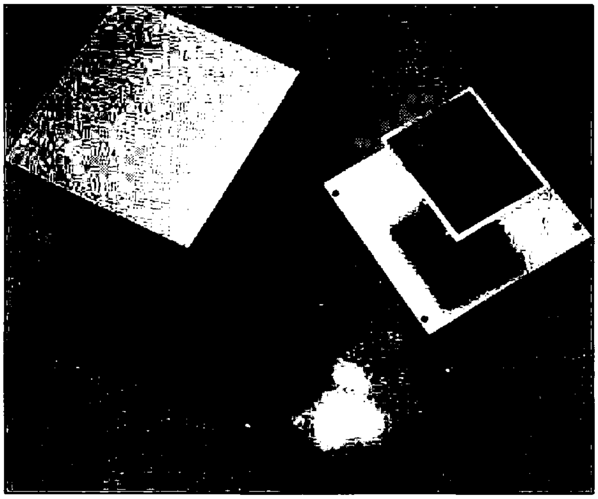

Photo C. Mounted lens, mounted horn and complete antenna.

Sound more complicated than it actually is? Say you have a reference antenna of 16 dB gain and with it you get a reference attenuator setting (reference reading for midscale meter deflection) of 8.5 dB. Putting your test antenna on the receiving setup, you get a midscale meter deflection with the attenuator changed to a setting of 12 dB. Then, subtracting the reference reading (12 − 8.5 = 3.5 dB), you find that the test antenna has a gain 3.5 dB greater than the reference. You have to attenuate the signal from the test antenna to make it equal to the reference signal. The gain of the test antenna is the difference added to the gain of the reference antenna (16 + 3.5 = 19.5 dB). If the midscale deflection had required an attenuator setting of 4 dB for the test antenna, then subtracting the reference reading (4 − 8.5 = -4.5 dB) tells you that the test antenna has a gain of 4.5 dB less than the reference, or a net gain of 16 − 4.5 = 11.5 dB.

You do not need to know the absolute gain of an antenna to use this technique. As long as you use the same antenna as a reference, you can measure the relative gain of your other antennas to it. After all, we are more interested in reducing losses or improving gains than we are in knowing what the absolute levels are.

Back to the lenses. The lenses, having a focal ratio (or F#) of about 1, should be fed with some sort of small horn antenna. I used the only one I had at the time—a Microwave Associates metalized plastic 17 dB gain horn. The addition of the epoxy lens increased the gain by 4.5 dB, or a factor of 2.8. With a unit at each end of a path, the net system gain is 9 dB, allowing the usable separation to be increased by 2.8 for equal signal strength. I was able to mount the lenses on one face of a 6-inch cube steel utility box and mount the horn with a spacer on the opposite face of the box. The result is a compact, easy-to-handle unit that can be readily mounted on a tripod for field work, or on a tower for point-to-point applications. (See Figure 5.)

I am now looking for a larger lens to cast, or perhaps I can find a large bowl to serve as a mold.

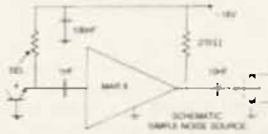
Need Another

NOISE SOURCE?

It is often desirable to see the performance of RF devices over a large frequency range. Viewing with a medium sensitivity logarithmic system, such as the 107 Spectrum Probe™ or spectrum analyzer, is needed. Finding a signal source is the other problem. A signal generator can be manually varied over the range. This is the most accurate, but it is very slow — especially if band changes and leveling must be adjusted. A swept generator can be used, but viewing is difficult unless the generator frequency is locked to the spectrum analyzer frequency.

FIG. 11



An inexpensive solution is use of a noise source which generates a medium, but essentially constant, level of noise over the frequency range of interest. I designed my own (fig. 11) using the emitter-base diode of the "noisiest" (but constant with frequency) transistor I could find. The diode is reverse biased to break down, with the current adjusted for maximum noise. This is connected to a high-gain wide-band amplifier.

10dB per DIV

100 µV

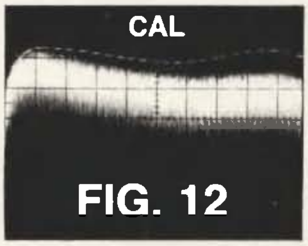


FIG. 12

frequency 100MHz

The Spectrum Probe™ display of fig. 12 shows the noise output, using the coaxial adapter and suitable termination. The noise generator is replaced by a −30dBm/7mv signal generator and this CAL also plotted in fig. 12. The small variation between noise and CAL indicates a nearly constant noise level. A 0.047 µF capacitor across the scope input will reduce the noise bandwidth.

The Microwave Directory

Where to find a wide range of goodies for operation at 902 MHz and above.

by Pete Putman KT2B

Ever wondered where to find chip capacitors? Low loss microwave relays? Power dividers? Isolators? Schottky diodes? Or perhaps you need a medium-power gain block to drive the high power amplifier you also need! Or tubes for it. Or even an antenna array. Stymied?

Hopefully, you won't be after reading through this compilation of microwave sources. I've spent a good deal of time rooting out sources for anything from ATC chips to Z-match devices...to help get your next project rolling. While this list is by no means exhaustive, it IS extensive and represents businesses from all over the US and Canada. In most cases, the proprietors are also amateurs, active in a wide variety of microwave operations.

Take a careful look. There are some really neat items available, and all at prices that won't break the bank! Most of these dealers will supply you with a catalog upon request. Each is listed with a brief description of the product(s) sold and any observations I have from past dealings. So, without further delay...

Advanced Receiver Research
PO Box 1242
Burlington CT 06013
(203) 582-9409
VISA/MC accepted

Jay Rusgrove W1VD has been building some beautiful preamplifiers over the years, and makes a nice sequencing board for mast-mounted types. ARR also sells the TR10GA Gunnplexer/Transceiver combination for wideband 10 GHz FM work as well as the TR24GA system for 24 GHz. A line of microwave preamps is in the works. Catalog available.

Bob Seydler
Rt. 2 Box 2170
Boerne TX 78006
(512) 650-3001 Days; (512) 249-2152 Eves.

Bob N5KET and Alan Dickinson N5BHX have accumulated a huge quantity of surplus microwave equipment, ranging from power amplifiers, isolators, Gunn diodes and Gunn oscillators, PLL/DRO oscillators, complete transceivers and components. PHEW! If you can't find it here, then where? Price list available.

Communications Concepts, Inc.
508 Millstone Dr.
Xenia OH 45385
(513) 426-8600

A source of hard-to-find chip caps, RF power transistors, and kits for VHF and UHF. Catalog available.

Distributor Specialists
1942 14th Street
Santa Monica CA 90404
(213) 452-3445

Distributor Specialists carry a full line of high-power relays including Dow-Key Type 60 and 260 series and Marshall CX500 series. Price list available.

Down East Microwave
Box 2310 RR1
Troy ME 04987
(207) 948-3741
VISA/MC accepted

Home of the famous "loopers"! Bill Olson W3HQT is the proprietor, and in addition to loop yagi kits for 903, 1296, and 2304 MHz, he manufactures a line of linear solid-state amplifiers for 903 and 1296. Power levels range from 3 to 70 watts output. In addition, Down East carries the SHF Systems series of transverters for 902 through 5760 MHz. Low noise preamps and kits are available for 432 MHz through 10 GHz. Catalog available.

EMCOM Industries
Ed Emich
10 Howard St.
Buffalo NY 14206
(716) 852-3711

Contact Ed Emich KB2KHK for waveguide and 10 GHz frequency meters. He also can design prototype specialty microwave items for your specific needs.

Frontier Microwave
RD1, Box 467
Ottsville PA 18942
(215) 795-2648 Eves.

Dave Mascaro WA3JUF has been building solid-state gain blocks for quite some time, and offers a line of custom-built amplifiers to cover the spectrum from 902 to 2304 MHz, with power levels from 10 mW to 50 watts. He also builds low-noise preamplifiers for 902 and 1296. They're good for a variety of applications as low-level drivers or final stages. Price list available.

Hamtronics, Inc.
65 Moul Rd.
Hilton NY 14468-9535
(716) 392-9430

A lineup of kits and modules for VHF and UHF including 900 MHz. High quality and economical GaAsFET preamp kits from 10m through 70cm. Catalog available.

Hi-Spec Company
PO Box 387
Jupiter FL 33468
(407) 746-5031

If you're ready to add a bit of power to your microwave signal, Hi-Spec would be a good place to start! A full line of cavity amplifiers is available for 902, 1296 and 2304 MHz. And you can now gang 'em up with the Hi-Spec line of modular RF decks, using a common high voltage supply (yours or theirs). Up to 200 watts out can be obtained on 903 and 1296, with up to 100 watts available on 2304...a potent punch. Price list available.

Microwave Components of Michigan
PO Box 1697
Taylor MI 48180
(313) 753-4581 evenings

Another regular visitor to Dayton! Norm Alred WA8EUU is the proprietor, and he's got quite an assortment of hard-to-find com-

ponents, such as chip and leadless capacitors, chip resistors, microwave diodes, GaAsFET devices, MMICs, piston trimmers and SMA connectors as well as a lineup of Mitsubishi power modules. Norm also builds some nice low-noise preamps from 6m to 1296 MHz. Price list available.

Mountaintop
P.O. Box 178
Somis CA 93066
(805) 482-0320
(Answering machine during daytime or contact directly after 7 pm PST)

John Kitchens NS6X offers a selection of surplus VHF, UHF and microwave parts. He also has MA/COM 10 GHz Gunnplexer systems as well as sideband units for 10 GHz. He still has some of the popular Tonna antenna line in stock.

Pauldon Associates
210 Utica St.
Tonawanda NY 14150
(716) 692-5451

Preamps and power amplifiers for 2m up to 1.2 GHz. Bricks and exciters for 70 cm, 900 MHz and 1.2 GHz. Catalog available.

PC Electronics
2522 Paxson Lane
Arcadia CA 91007
(818) 447-4565
VISA/MC accepted

Always wanted to be TV, eh? Tom W6ORG and Maryann WB6YSS O'Hara can satisfy your craving with a full line of ATV transmitters and accessories for 70cm, 902 and 1296 MHz. Receive converters are also available, and you can even buy the boards to "roll your own" ATV station. Amplifiers and antennas round out the equipment list. Catalog available.

RF Parts
1320 Grand Avenue
San Marcos CA 92069
(619) 744-0728, (800) 854-1927 order line

All kinds of RF power transistors and parts for VHF and beyond. Power modules (bricks) for a variety of bands and input power are available to help simplify amplifier projects. Specialty tubes can be had as well. Catalog available.

Satellite City
2663 County Road I
Moundsville MN
(612) 786-4475
(800) 426-2891

An economical source of 18" and 24" dish antennas as well as Gunnplexers and associated equipment. They also have some real deals on used satellite equipment for FM ATV experiments.

SHF Microwave Parts Co.
7102 W. 500S
La Porte IN 46350

Alan Rutz WA9GKA carries a smorgasbord of equipment for 10 GHz experimenters. Gunnplexers, Gunn diode sources, horns and waveguide are among some of his offerings.

Sinclabs Inc.
Specialty Products Div.
85 Mary St.
Aurora, Ontario, Canada L4G 3G9
(416) 841-0624
In the U.S. contact:
East Coast Amateur Radio
496 McConkey Dr.
Tonawanda NY 14150
(716) 835-8530

For those high-power enthusiasts, Sinclabs produce a nice series of water cooling jackets which mount on a 2C39, 7289 or 7815 tube. Also they offer 900 and 1296 MHz 2-way power splitters. 10m to 2m or 220MHz transverters are available as well. Catalog available.

Spectrum International
P.O. Box 1084-S
Concord MA 01742
(508) 263-2145

For years John Beanland G3BVU/W1 has carried the fine line of Microwave Modules transverters and converters. Although Microwave Modules no longer supply the ham market, he still has some 1296 transverter boards available. He will continue service and repair for any of the units out in the field. John carries a lineup of loop yagis for 1268, 1296 and 1691 MHz as well as a series of high quality interdigital band filters from 420 MHz up to 1691 MHz. ATV channel filters are available designed for specific frequencies. He also offers a wide range of equipment for GOES weather satellite reception on 1691 MHz including a complete high quality system. Look for more interesting transverter packages in the coming year. Catalog available.

SSB Electronics USA
124 Cherrywood Dr.
Mountaintop PA 18707
(717) 868-5643 M-F after 6:30 p.m. Any time on weekends.

Gerry K3MKZ carries the high quality SSB Electronics series of transverters from 6m all the way up to 10 GHz. Also a line of preamps for EME, OSCAR and weak-signal work both mast-mounted or in the shack. A mode S receive converter is available as well. Check out their 100 watt amp for 1200-1300 MHz. A 40-page catalog is available for 85 cents worth of stamps.

Steve Kostro
Box 341A RD1
Frenchtown NJ 08825
(201) 834-1304 9 a.m.-7 p.m.
(201) 996-3584 after 9 p.m.

Steve N2CEI is another "partsmonger" and at hamfests he sets out a tray of components that looks good enough to eat. You'll find all kinds of bipolar and GaAsFET devices available as well as MWA and Avantek MMICs; HP-5082 diodes, chip components, helical filters, connectors and Teflon™ PC board material. Steve also sells a line of GaAsFET kits based on the WB5LUA designs for 902, 1296 and 2304 MHz. Price list available.

Surplus Sales of Nebraska
1315 Jones Street
Omaha NE 68102

The Commander II Amplifier

For more fun on 2 meters.

Command Technologies, Inc.
1117 W. High Street
PO Box 939
Bryan OH 43506
Tel: (800) 736–0443; (419) 636–0443
Price Class: $1388 w/Dow-Key 260-B.
Price Class: $1140 w/o 260-B.

The Commander II amplifier, manufactured by Command Technologies, Inc., is a 2 meter operator's dream come true. It uses a single 3CX-800A7 in a grounded-grid configuration, running in class AB2. The tube itself is capable of 800 watts plate dissipation, which is comforting since the amplifier can put out almost 1000 watts SSB with 25 watts of drive! And all this high power is in a compact, self-contained table-top unit (see Photo A). The amplifier weighs 56 pounds, most of its weight due to the heavy duty transformer used for the 2500-volt, high voltage supply and 12-volt control voltages.

The layout of the amplifier is straightforward and clean. The final amplifier section is in a completely RF-tight enclosure mounted inside the cabinet. It contains the 3CX-800A7 tube with a Teflon™ chimney. The blower is a 50 cfm Dayton squirrel-cage type, which moves plenty of air around the tube, but it won't knock your ears off while running (see Photo B).

Input and Output Circuits

The input circuit is a high Q-tuned type which provides excellent linearity and low SWR for the exciter. I found the tuning to be sharp, though very manageable thanks to the 6:1 vernier gear drive connected to it.

The output circuit uses a quarter-wave stripline design with a high Q piston-type plate tuning capacitor, both of which are machine fabricated of brass then silver-plated. This tuning capacitor moves in and out of a fixed cylinder attached to the stripline. Teflon™ is used for the dielectric, and there is no problem with arc-over since the capacitor is rated at 2–26 pF at 10,000 volts.

Two pre-sprung straps, which give while turning on a screw-type shaft, ground the piston. The tuning capacitor and loading capacitor are connected to 6:1 vernier gear drives for smooth tuning. High voltage enters the plate circuit through a mil-spec "MHV" connector similar to a BNC. Bypassing is done at the connector with a 0.005 µF capacitor at 5 kV, and an open-air type RF plate choke in series with the high voltage lead is attached to the tube by a collar wrapped around the plate. The filament supply is bypassed at the input terminals, and RF chokes are in series with the supply voltages.

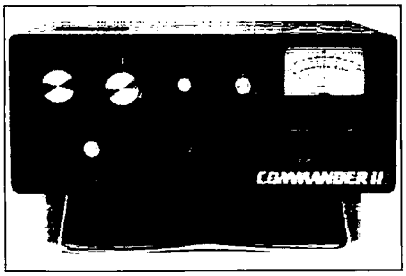

Photo A. The front of the Commander II.

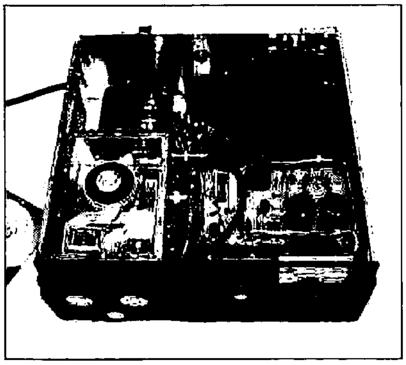

Photo B. Under the cover, a quiet fan keeps things cool.

RF Flow

As the RF leaves the output circuit through the SO-239 connector, it meets a "T" connector, one side having a quarter-wave shorted stub and the other side having a piece of ¼" heliax for the output, which is attached to the Dow-Key 260-B RF relay (the relay is optional; see "Price Class" above). The blower output to the tube is shielded by a stamped-out top cover plate with enough surface area to keep the RF inside; however, there is plenty of air output during operation. The entire RF section uses machine screws and lock-washers to provide excellent RF shielding and grounding.

Typical RF Output Ratings for the Commander II

Watts Drive	Watts Out
5	120
10	320
15	450
25	700

The Power Supply

With all this attention to a highly efficient RF section, the next question that pops up is, where is the power supply? It's in the same compact cabinet as the RF section, but completely separate from it. The Commander II comes wired for 110 VAC, with a large seven-foot #14-3 conductor AC cord. This was a pleasant surprise, and definitely needed to keep the voltage drop down on the primary supply at full output. The amplifier can also be wired for 220 VAC, which I did, and I noticed better regulation as a result.

The filament transformer is not part of the high voltage transformer. This provides for better regulation and no voltage drop at the filaments under full load. The high voltage transformer is large and heavy, 28 pounds worth, exactly half the weight of the amplifier. It sends 900 volts AC to a voltage doubler that generates about 2500 volts DC with 27.5 µF of filtering using eight 220 µF, 450-volt capacitors. A 50-ohm, 50-watt resistor in series with the high voltage lead limits the current in the event of a short or flashover in the tube.

A single meter switched in and out using a multiple pole switch mounted with a small PC board on the back, provides plate voltage, plate current, and most importantly, grid current. The control board, mounted on top of the high voltage board, gives the two-minute time delay needed for the cathode of the tube to warm up before operation can begin. The regulated 12 volts for relay control, and a zener diode for proper class AB2 bias, are also a part of this board.

Operating the Commander II

The operation of the Commander II is very easy. When you turn on the amplifier to warm it up, the meter's lamp lights up and high voltage is present on the plate of the tube. The green lamp will come on when the two-minute

delay circuit is complete, and at that point the amplifier is ready to go.

The 12-volt relay circuit requires a hard contact closure to ground rated at 150 mA of current draw. When you key the amplifier without drive, the plate current reads about 120 mA, and the grid current should be zero. I found no erratic plate or grid current readings at this point while tuning the plate and load controls along with the input tuning. This means the amplifier is very stable and won't go into oscillation while the drive is still at zero.

The nominal input drive is 10 to 15 watts, while 25 watts is maximum. As seen by the table, even 5 watts will give over 100 watts output. This amplifier really runs well. I found its efficiency at about 60% or better, depending on the drive. Wiring the amplifier for 220 VAC resulted in better regulation, with about a 150-volt drop in the high voltage supply at full output. If you have a dedicated line for the amplifier, it can run fine at 110 VAC, drawing close to 14 amps at full output.

Easy to Tune

Overall, tuning is straightforward. For the most part you are looking for maximum output while checking to make sure the grid and plate currents are not exceeded. I used a Bird Model 43 with various elements, up to 1000 watts for all tests. My own station consisted of a multimode Yaesu FT-901DM, with the FTV-901R transverter at 15 watts for some of the testing; and a multimode Yaesu FT-736R VHF and UHF rig at 25 watts for the high power testing.

My transverter only had 15 watts, but even at that level my output was still 450+ watts! With the 25 watts from the FT-736R, this amplifier really puts out the power—at least 700 watts! And if you really watch the grid/plate current and don't exceed maximum ratings, you can get almost 1000 watts power SSB.

On-the-air checks while running SSB were all very good, and I had no bad reports of audio distortion or splatter up and down the band. In fact, most people commented on how good the amplifier sounded! Putting the amplifier in and out of the line was fun, since the gain difference is about 15 dB! And that's really handy when trying for that extra grid square on 2 meters.

I also run plenty of FM simplex with key-down times of 5 to 10 minutes for each "go-around" during an entire evening. There has been no problem with the amplifier as long as I keep the power output around 400 to 450 watts. Don't let it get any higher than that on FM unless you want to purchase a new tube soon! After having the opportunity to run this kind of high power on 2 meters for the past couple of months, I see a whole new world open up.

Most of the rigs today have good receivers, but unless there is something such as the Commander II in the output, the score is not even. I was always hearing very well, but now I can work anything that comes through on the receiver!

One final note: I am really glad to see an all-American company producing such a well-made piece of equipment! 73

Wyman Research, Inc.
R.R. #1, Box 95
Waldron IN 46182
(317) 525-6452

Don Miller W9NTP offers a lineup of FM video transmitters and receivers for the 900 and 1200 MHz bands. He also carries a series of AM ATV transmitters, receivers and transceivers for the popular 70cm band as well. Catalog available.

Well . . .there you have it. Again, the list is by no means exhaustive! Surely there are more entrepreneurs out there peddling microwave components at hamfests than I know about. And, of course, I purposefully omitted the major manufacturers who already heavily advertise their microwave products, such as transceivers and preamplifiers for 23 centimeters.

Clip this article out (or put this issue aside) to use the next time you come up against a wall when searching for parts or whole assemblies. Amateurs are supposed to be a resourceful lot. Above 900 MHz, you haven't much choice! This will make the job easier.

See you on 902 . . . 1296 . . . 2304 . . . 3456 . . . 5760 . . . 10368 . . . etc. . . . 73

HOMING IN

Radio Direction Finding

Joe Moell, PE, KØOV
PO Box 2508
Fullerton CA 92633

Leveling the Field

In Radio Direction Finding (RDF) contests, as in every other sport, it's important for winners to be determined by fair and uniform methods. One of the students in our local beginners' ham class is a former world class ice dancer. He has told us horror stories of the subjective scoring system for competitions. Standings are determined by a panel of judges, and "hype" appears to be as much a factor as talent and skill in winning the gold.

Fortunately, foxhunt winners aren't picked that way. We can use objective criteria for scoring. But which criteria to use and how to apply them can lead to controversy. It's important for all hunters to feel that they have a fair chance of winning, or they won't participate regularly.

And...They're Off!

An obvious method for selecting T-hunt winners is to use a watch. Everyone starts hunting simultaneously, and the first finder wins. Easy, right?

This method is the favorite of the "sportsman" type of hunter, as well as those who view foxhunting primarily as practice for jammer hunts or search/rescue missions, where speed is all important.

But many foxhunters abhor time-only hunts. "These hunts favor the athletic hunters and the daredevils," they say. In an on-foot hunt, a participant with a physical disability is at a disadvantage. In vehicle hunts, time factors discourage safe, courteous driving skills. Other hunters may be willing to push the speed limit. Are you?

The biggest complaints about time hunts arise when locals and out-of-town hunters face off. Traditionally, San Diego (California) hunts are always time-only events. When San Diego hams host a big convention and put on a T-hunt, many Los Angeles and Santa Barbara area attendees gripe about the likelihood of the San Diego teams winning all the prizes, because they know the fastest routes on the local freeways and highways. Of course, these gripers usually don't participate in that hunt, so it becomes a self-fulfilling prophecy.

Maintaining interest on a long timed hunt can be difficult. If the hider lets it slip out that at least one team has found the T, the other hunters know that they cannot win. They may quit at that point and go home, unless the hider can keep them going by baiting them, promising them snacks, etc.

Some club rules allow hunters to start anywhere, perhaps on a hilltop close to their home. Almost always, these are time-only hunts. Of course, there is an element of luck involved, because some hunters will start much closer to the T than others.

Another problem occurs when teams get the same start bearing and follow one another. It's bad enough when it causes a drag race on a vehicle hunt, but it's even worse when foot-hunting. The first finder must be careful not to give away the location of a concealed T to others who are sniffing nearby.

World class foot-hunt competitions often use a "staggered start" to avoid this problem. Competitors start at regular intervals, and each of them is independently timed from start to finish. That's fine for a European radiosport championship, where there are plenty of judges available to do the timing, but it's impractical for small club outings when everyone wants to hunt and no one wants the timing chores.

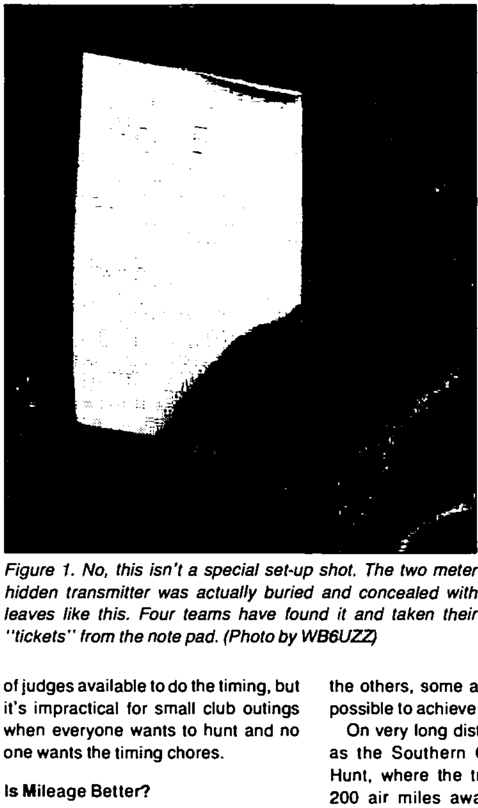

Figure 1. No, this isn't a special set-up shot. The two meter hidden transmitter was actually buried and concealed with leaves like this. Four teams have found it and taken their "tickets" from the note pad. (Photo by WB6UZZ)

Is Mileage Better?

Of the 15 monthly hunts in the greater Los Angeles area, only three use time as the sole factor for winning. The rest use mileage, either as the only factor or the most important factor. Using odometer mileage eliminates racing and timing problems. It helps level the field for new competitors, who are less familiar with local geography and the operation of their RDF gear.

Eliminating time as a factor encourages hunters to be careful and methodical. Mileage hunts are preferred by "engineer" types (like me) who view a T-hunt as a field experiment in propagation and navigation, instead of as a blood sport.

Mileage hunts can be almost as simple as timed hunts. Odometers are read at the beginning and the end point. The lowest mileage wins. Traffic tie-ups, poorly-timed stop lights, long freight trains, and open drawbridges don't ruin your day on a mileage-only hunt.

Mileage hunts have their own problems, however. Some hunters take advantage of the lack of a time penalty and hunt v-e-r-y slowly, perhaps stopping for leisurely meals along the way. Needless to say, this is very annoying to the hider, who wonders when he or she will get to go home.

If an on-foot search is involved at the end of a mileage hunt, it's easy for some lazy or poorly equipped teams to hang around and watch someone else try to ferret out a carefully concealed transmitter (see Photo A), instead of going after it themselves. After all, they found the parking area, so their place in the finishing order has already been determined by their mileage. There is no incentive to dig out the sniffing gear.

What's Your Crenshaw?

The biggest problem with mileage-only hunts is odometer calibration.

Whenever teams finish with mileages a percent or two apart, there will be controversy. I am told that continuing odometer arguments led to the San Diego hunters changing to time-only hunts. One or two teams always had significantly lower mileages than the others, some appearing to be impossible to achieve by any route.

On very long distance events, such as the Southern California All Day Hunt, where the transmitter is often 200 air miles away, a five percent odometer error (quite common) frequently changes the order of finish. That is why a standard method for normalizing mileages was devised. It's called the Crenshaw Factor, because each hunter calibrates his odometer by driving a carefully-defined section of Crenshaw Boulevard on the way to the starting point.

Hunters read their odometers with the nose of the vehicle alongside a telephone booth in front of a certain doughnut shop, then drive in the left lane to the stop sign at the starting hilltop and read it again. The elapsed mileage is the vehicle's Crenshaw Factor, usually about nine miles.

It takes only a few seconds with a calculator to determine the winner of a close hunt with Crenshaw Factors. Just divide each hunter's odometer hunt mileage by his or her Crenshaw Factor. The results, in Crenshaw Units, are compared. The winner has the lowest number. Some hunters don't like results to be expressed in Crenshaw Units, so they multiply the Crenshaw Units by 9.0 to get approximate corrected mileages.

That explanation may seem a bit complicated, but actually it's very simple and quick to do. "What's your Crenshaw?" is being heard at the end of hunts quite often, even the shorter ones. There are far fewer disputes, merely occasional snide comments about the "inflation" of claimed Crenshaw Factors over time.

Pick Your Combination

Mileage-only and time-only hunts each have good and bad features, as we have seen. This has led many clubs to adopt rules that include both time and mileage factors, trying to get the best of both worlds.

Most Fullerton (California) Radio Club hunters like their system, where the final score is the sum of odometer mileage, plus a time penalty of one-tenth mile per minute from start to touching the fox's antenna. Lowest hunter's score wins, of course. This system encourages careful triangulation and route planning, while also keeping the hunters moving along and forcing rapid sniffing. On the other hand, some feel that the time penalty turns this hunt into a road race.

Some clubs have additional methods of scoring that include keeping track of the progress of all participants over the course of the annual foxhunting season. In Lincoln, Nebraska, the first finder of each hunt gets 15 points, second gets 10, third seven, and so on. All participants, including navigators, get at least one point.

Even the hider scores in the Lincoln ARC system. He or she gets five points if not found in 30 minutes, and additional five points for each unfound 15 minutes after that, up to 25 points. Cumulative standings are updated monthly and posted in the club newsletter.

To make hunting more of a challenge in the flatlands of Nebraska, foxes transmit for two minutes, then are silent for three minutes. The hider uses the high power mode on the rig until one hunter requests a switch to low power. From there on, each transmission is one minute at high power and one minute at low power, to aid hunters who use rudimentary attenuation methods.

Now that you know the pros and cons of various scoring systems, your group can make up its own set of rules. Get started now, because the warm weather hunting season will be here soon. Be sure to take pictures of your group's most interesting RDF setups and clever fox dens. I am always looking for good photos and interesting hunt stories for this column.

An Inexpensive 10 GHz Dish System

The plumber's delight!

by Jerry Jensen WTØW

This design for a 10 GHz dish and feed system was born of necessity. There are few sources of microwave components here in the Midwest, so construction projects have to use available non-microwave parts. The only microwave part used for this system is one WR90 waveguide flange. Even that could be made of scrap material if you can't locate one easily.

The dish is an old 18″ surplus HBO dish left over from the days when premium channels were broadcast. It has a focal ratio of 0.4, providing a focal length of about 8.1″. The dish I found has a 1″ hole, conveniently located at its center, that permits the 10 GHz source to be mounted behind the dish and fed through it to a modified "penny feed." A chassis punch or drill could be used to make the hole on a solid dish. One of the old "flying saucer" dish snow sleds would also work if you modify the feed's length to meet the new focal ratio.

The feed system starts out as a 12″ piece of ¾″ copper pipe. Anneal one end of the pipe by heating about 2″ of the end until the surface looks very clean (don't get it red hot), then plunging the hot end into cold water. This will make the annealed end of the pipe very soft and easy to work. Place about ½″ of the end in a vise and squeeze the pipe with the vise until the pipe is an ellipse about ½″ wide. Next, rotate the pipe 90 degrees and do the same thing, but stop at 1″, at right angles to the first squeeze. By repeating the operation a few times, you will end up with an end on the pipe that fits the WR90 flange. Pliers and careful hammer tapping (with a sharp right angle piece of steel held inside the pipe) will make the corners of the squeezed pipe perfect. Be careful not to strike the copper hard enough to stretch it or you will end up with too large an opening.

Once the end of the pipe matches the flange, force a ¾″ outside pipe coupling (just a copper tube that fits over the joint of two ¾″ pipes) down the pipe to as near the flange end as possible. This will act as a spacer for the next plumbing piece, a 1″ male pipe threaded to a 1″ copper pipe adapter. Put the adapter over the pipe coupling with the male threaded end away from the waveguide flange. Some adapters fit over the coupling tightly, others are a bit sloppy. A layer of clean copper wire can be wrapped around the coupling, or a single turn used at the end(s) for spacers as needed.

Before the assembly is soldered, mount a 1″ galvanized pipe flange on the back of the dish over the 1″ feed hole in the center. Screw the copper adapter about halfway into the flange and measure the length of the pipe sticking into the dish. Check to be sure that the end of the pipe goes into the dish at least far enough to be within an inch of the focal point. If everything checks out, solder the waveguide flange to the pipe and the pipe coupling and adapter assembly. If you get any solder inside the end of the waveguide at the flange, use a small file to remove it.

Screw the feed assembly about halfway into the pipe flange, mark and then cut the copper pipe to make it about 1½″ short of the focal point.

At this point there is an option. If you want to be able to tear down the system into its most portable state for backpacking or such, you can make the splash feed removable. This will allow you to pull the feed system out of the dish. The feed system and splash plate can then be packed inside the dish.

The splash plate assembly is made from a male ¾″ pipe threaded to a ¾″ copper pipe adapter, a PVC (plastic) ¾″ female pipe threaded to a pipe adapter, and a 3¼″ copper disk. The PVC adapter is epoxied to the center of the copper disk. This is then screwed on to the pipe thread of the ¾″ copper adapter and the disk. For a completely portable system, drill and tap the copper adapter for a set screw to hold it to the feed system (an extra nut soldered to the outside might be wise). For fixed operation, solder the copper adapter to the radiating end of the feed system.

Tune Up

Tune up is simple: The radiating end of the feed has to be set to the dish's focal point. Then the separation between the end of the waveguide and the splash plate is adjusted for maximum radiation.

You will need some sort of power or signal strength measuring device to make these adjustments. It can be as simple as an unpowered Solfan unit. Just measure the mixer diode current of the unpowered unit when it is placed a few feet away from the dish with a sensitive current meter. Another Gunn transceiver could also be used to peak the signals.

The feed system can be adjusted by screwing the assembly into or out of the dish. The splash plate can be adjusted by screwing the PVC adapter further on or off the ¾″ pipe thread. These adjustments interact and should be made to optimize the gain of the system.

If you have built the portable system with set screws, be very careful not to distort the ¾″ copper pipe waveguide when you tighten the screws. If everything has been done correctly, the polarization of the output will be within a few degrees of the original source. If small dents or distortions are introduced into the pipe, the polarization of the output will rotate.

An 8-32 screw can be inserted into the center of the copper disk and adjusted to scatter the RF energy better as it hits the disk. The copper disk can be made from a piece of single or double-sided PC board. The PVC adapter could be machined from a better microwave plastic for lower losses. During the machining, a dielectric lens structure could be formed to optimize the scatter from the disk.

This disk and feed system may not be perfect, but it is a usable system that can be made from hardware store plumbing parts. Total cost, without the dish, should be less than $5. The feed illumination is good, and there is very little measurable radiation escaping the dish. Measurements taken across the dish (built with the dimensions shown) show a reasonable illumination pattern. 73

Contact Arthur J. (Jerry) Jensen WTØW at 10900 Ewing Ave. S., Bloomington MN 55431.

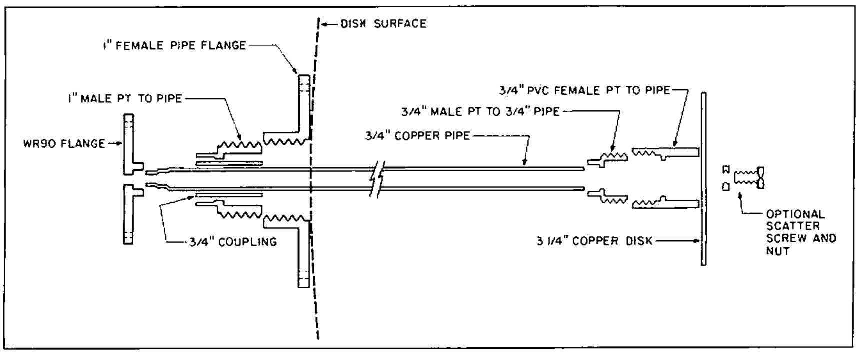

Figure 1. Assembly of the 10 GHz dish and feed.

Parts List

1	12″ length of ¾″ copper water pipe
1	¾″ male pipe thread to ¾″ pipe adapter
1	¾″ female—female pipe coupling
1	¾″ PVC female pipe thread to PVC pipe adapter
1	1″ copper male pipe thread to pipe adapter
1	1″ galvanized iron female pipe flange
1	WR90 waveguide flange
1	3¼″ copper brass disk

Note: 18″ and 24″ dishes are available from Satellite City, 2663 County Road I, Moundview MN; (612) 786-4475. Costs are about $20 and $30 respectively.

Microwave Mixers

There are so many different types of microwave detectors available that I couldn't fully describe them all to you. What I will do is describe some of the more common types I've observed in surplus, the most familiar being the double balanced mixer (DBM) that's similar to the SRA-1. I have used this mixer in many different converters. You'll find various applications for it in almost any ARRL handbook.

Most devices run out of steam at 500 MHz; some special types, such as the TFM-1, are capable of operation up to 1500 MHz. But for our microwave bands, we need mixers that operate at frequencies from 2.3 GHz to 10 GHz and above.

Some prepackaged microwave mixers come with coaxial connectors attached to their three ports: RF (in/out), IF (in/out), and local oscillator, L.O., injection. Yes, that's "in/out," as any mixer can be used in receiving or transmitting. Mixer ports are labeled R (for RF), L (for L.O.), and X (for IF). Package styles can vary quite a bit. Usually, but not always, the bigger the package, the lower the frequency.

An SSB Modulator

At a flea market, I found a device labeled "SSB Modulator" that was 3½" high, 5" long, and ½" thick. (See Figure 1.) Quite a monster as mixers go. The price was right, so I picked it up. I thought it would be a 500 to 1.5 GHz low frequency mixer of some type, but when I tested it, it failed to perform at these frequencies. I opened it up to see what was going on.

Access to the inner parts was hampered by bolts epoxied and painted over. After scraping the paint off and picking the epoxy away with a knife, I was able to remove the bolts. The unit split into two sections (top and bottom plates), revealing the inner circuitry.

Looking at the circuitry, I could see it wasn't defective. The device was a very high frequency phase combining type of mixer. The actual mixer circuitry was about ¾" square, definitely not 1 GHz stuff. I put the unit back together and tested it at a much higher frequency, and found that it functioned in the 8 to 12 GHz range.

It's difficult to represent all the details of this mixer, but it uses four diodes and has combining striplines on both the top and bottom of the very thin PC board, coupling and phase canceling RF from port to port. This method achieves a high degree of balance, improving unwanted mixer products from either the USB or LSB inputs. Needless to say, I was excited.

If an item is inexpensive, take a gamble and pick it up; you do not know what you might be missing. True, the mixer could well have been another doorstop, but no gamble, no chance of winning.

Another type of mixer common on the surplus market is waveguide mixers. You can identify their frequency by the size of the attached waveguide. Figure 2 shows a typical waveguide mixer. This unit has two mixer diodes and usually comes with an internal preamplifier optimized around 70 MHz. This is a common IF for commercial systems. One of the waveguide ports is the RF input and the other is the local oscillator injection for the mixer. I have interchanged them with no ill effect.

Two caps about ½" in diameter allow you to service the detector diodes, if necessary. Note that this mixer only uses two diodes; one is positive and the other diode is reversed in polarity. The circuit works just like a full-wave rectifier in an AC/DC power supply.

Testing microwave detector diodes is simple, as they have a standard junction and will test like a basic diode. One problem is that the voltage rating and current permitted through these microwave diodes is quite low, and in testing them, use caution not to exceed limits. The old reliable 1N21 (6 GHz) and 1N23 (10 GHz) diodes used can be tested with a basic ohmmeter. Use the times 10 scale to limit current, and it will show you if the junction is still alive. This will not guarantee any figure of merit (noise figure) of the device. If the device is a good noise-figure type, you might want to wait until you can test it in a circuit.

I would not want to subject expensive diodes to the ohmmeter test. You must use good judgement, since some of the newer devices, such as GaAs types, will be destroyed or degraded by test voltages near 5 volts. I would limit the meter test to the 1N21 and 1N23 diodes. The GaAs type mixers have static-sensitive junctions and can easily self-destruct with improper handling. Test GaAs devices in a circuit, after the device is built, not with the ohmmeter.

A mixer similar to the waveguide type operates at lower frequencies. The waveguide may not be attached because a larger size is required. Normally, the waveguide ports are replaced with two "N" connectors on the opposite side from the detector diode caps. The basic body contains the same IF type amplifier described above. See Figure 3, which describes a mixer for 5.6 or 3.3 GHz operation. These mixers come from aircraft radar and some communications systems. Several variations are starting to appear in surplus.

The "ortho mode" waveguide mixer (see Figure 4) takes a totally different approach by coupling the RF and L.O. ports in a unique way. This mixer is waveguide orientated, with the RF port rotated 90 degrees from the L.O. port. This further isolates the ports. (Normal isolation between cross polarization is a minimum 30 dB loss). The IF amplifier could be bolted to the mixer, but usually the mixer is by itself. IF connections are made to both the detector diodes, one positive and the other reversed or negative. If you have one of these mixers, you can combine the detector diodes with two coupling capacitors to form the IF output. Don't forget to provide a DC return for the mixers. A small RFC will do the trick.

Now you might ask, "Why all the information on these mixers?" Well, they work and they're relatively inexpensive, costing about $10 to $20 each in surplus. You can use them to construct a high quality SSB or narrowband FM microwave converter. They may not be the latest state-of-the-art mixers, but they will work as well as the expensive types. Size is the only drawback.

Mixer Perspective

Of course there are several other types of mixers suitable for our microwave bands in addition to the types described. These can be single-balanced, double-balanced, quadrature IF, image rejection, rat race, and even triple balanced types. Mixers are rated by conversion loss and noise figure. Conversion loss is the ratio of RF input power compared to the IF output power. Noise figure, expressed in decibels, is the ratio of signal to noise. The lower the decibel value, the better the mixer will perform in receiving weak signals.

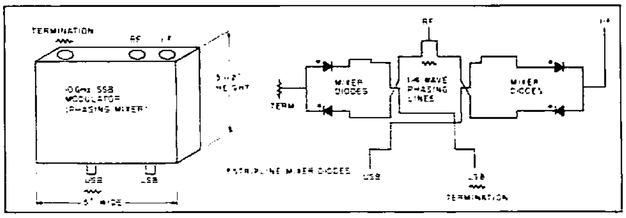

Figure 1. Surplus SSB modulator for 10 GHz.

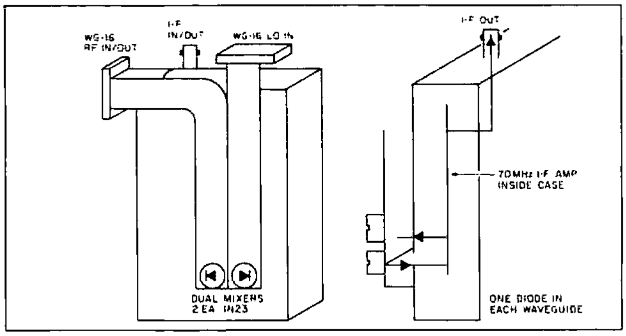

Figure 2. Waveguide mixer for 10 GHz.

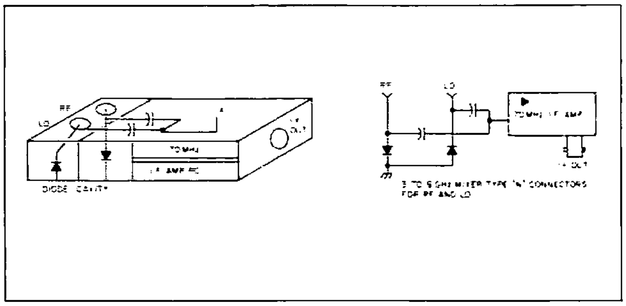

Figure 3. Mixer for 3–6 GHz range.

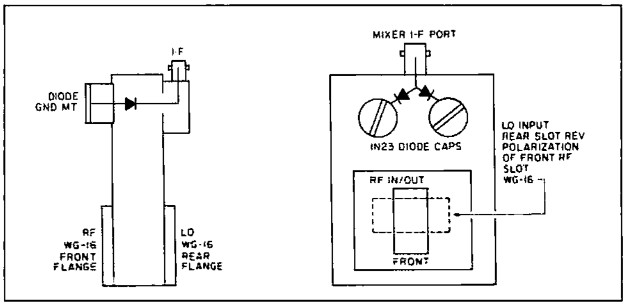

Figure 4. The ortho mode mixer 10 GHz (good for SSB 10 GHz), inexpensive in surplus, has good port isolation.

Keep looking at flea markets and swap meets. Don't turn up your nose at some old grubby box with a waveguide mixer weighing half a pound and covered with spider webs. Check it out. I usually tell friends: If it's microwave and the price is low, buy it.

Listings 1–3

Larry K1LPS inspired the program listings in this column. In designing Gunn oscillators and detector mounts, he wondered, "Just how far from the back of the cavity do you space the diode or pick up in a transition?"

The dimension is a quarter of a wavelength, however the measurement is abraded by the fact that it travels differently in a waveguide than in free space. Therefore, it is spaced a "guide wavelength" (one-quarter guide wavelength, actually).

I worked the formulas out, but usually came up with different answers. In the process of doing my math I make "misteaks"! Therefore, I put the formulas in a basic program that can run on almost any computer. The programs are short and can be typed in quickly. See Listing 1 for the free space calculation for guide wavelength, and Listing 2 for a corrected formula for sea level/humidity corrections. This program also corrects for computers like the Radio Shack Model 100 that can't take the square root of a negative number.

The program in Listing 3 is for figuring the dielectric constant of a double-sided printed circuit board. All you have to do is measure the capacity of the PCB, figure how many square inches of material you have, and enter it into the program. After a few calculations, you can make a chart to take to flea markets to determine if you are looking at Teflon™ or Fiberglas™ material.

From the Mailbox

Curt WA6TIP asks about the mike transformer, capacitor C34, and the value of the meter movement used in the 30 MHz IF system in the article, "10 GHz Fun," in the April 1990 issue. Well, Curt, the mike transformer matches the impedance of your mike (assuming dynamic) low Z, to the high impedance of the mike circuit. Mine was about 2k to 50k, a surplus type. In the article, pins 2 and 3 of the mike circuit were erroneously reversed. Pin 2 should go to the decoupling network and feedback resistor, and pin 3 ties to the mike circuit. Sorry about that.

Alternatively, you could replace the transformer with an electret mike (99¢ at Radio Shack). Convert the circuit by tying one end of the electret mike to pin 3 and the other end to ground, and couple a 15k resistor at pin 3 to +DC. Capacitor C34 was left off the parts list; it's a 10 µF bypass, noncritical. The meter movement was a sensitive-type 25 microamps. You can use any type of meter up to about 200 microamps.

Next, a letter from Jeffry N0MAU. He wanted to determine just how expensive it is to get on the 2 or 3 GHz bands. I believe it would cost about a hundred dollars for a kit of parts along with some good scrounging. That's why I am pulling for 10 GHz operation. You can get 10 GHz equipment inexpensively by scrounging local alarm companies for microwave alarm units. Alarm companies are tossing out microwave units in favor of newer systems. That would make a simple system for 10 GHz cost effective. The total cost of a simple system could be less than $40 if you scrounge parts.

Gary KD6RF wants to know if the PC board for the 30 MHz IF amplifier is still available, and if the price has gone up. Well, everything is going up, especially gasoline, but my price remains the same. Cost is still $10 for the PC board with the TDA-7000 chip, and a few other parts to help you defray costs. (See "10 GHz Fun.") I try to keep all items available to assist project building, as I feel this is a very necessary ingredient to promote low cost projects for our UHF/VHF microwave frequencies.

New developments in my shack include working on several laser related projects, and I'm looking for a few parts, especially head-on photomultipliers to use in an optical receiver. Already built is a unique circuit for the receiver, which I'll cover in a future column. I've built a diode detector, but I want to try the photomultiplier tubes out next because they are more sensitive. I would appreciate any help or information on a source of these tubes.

I'll be glad to answer any questions related to our VHF/UHF microwave bands or similar topics. Please send an SASE for prompt reply. Chuck WB6IGP 73

UPDATES

10 GHz Fun

Chuck Houghton's article, "10 GHz Fun," appeared in the April 1990 issue of *73*. See his "Above and Beyond" column, page 59, in this present issue for corrections. He states that in the article, pins 2 and 3 of the mike circuit were erroneously reversed. Pin 2 should go to the decoupling network and feedback resistor, and pin 3 ties to the mike circuit. 73

IT JUST NEVER OCCURED TO ME TO APPLY FOR A RECIPROCAL LICENCE BEFORE I CAME!

Germany and Yemen

Germany: The ARRL Awards Committee has accepted the following recommendations of the DX Advisory Committee:

Effective October 3, 1990, the German Democratic Republic, Y2 through Y9, is deleted, because that country was absorbed by the Federal Republic of Germany on that date. Contacts with Y2 through Y9 stations on or after October 3, and contacts with DA through DL stations on or after September 17, 1973, will be credited as contacts with the Federal Republic of Germany.

The committee doesn't mention the former East German stations with callsigns in the DM series; however, the official allocation for the Federal Republic of Germany is DA through DR, not DA through DL.

Yemen: Effective May 22, 1990, the People's Democratic Republic of Yemen, 7O, and the Yemen Arab Republic, 4W, are deleted. In their place, a new country, Yemen, 7O, is added effective the same date. March 1, 1991, has been set as the earliest date for submission of cards for credit for the new Yemen listing. Please do not submit cards for credit prior to that date. Honor Roll members who have made contact with Yemen since May 22, 1990, will be able to update their credits during the month of March 1991, prior to publication of the next Honor Roll listing.

DXCC Processing Backlog

In late October 1990, the ARRL staff, faced with a large backlog in processing DXCC applications, organized a special effort to speed things up. ARRL Business Manager Barry Shelley temporarily took charge, applying what he'd learned in banking, where daily processing of numerous transactions is commonplace.

Other new assignments at ARRL headquarters also helped to reduce the backlog. By early November, applications received in June 1990 were being processed, a delay of approximately five months. As the new process gains momentum, the delay should be steadily reduced to an acceptable period.

"Islands On The Air" Award Program

Possibly one of the many good things about DXing is the chance to learn world geography. The Islands On The Air (IOTA) Award program goes one step further. It gives you a reason to learn about the world's islands, many of which would otherwise go virtually unnoticed.

Shortwave listener Geoff Watts created the IOTA Award program in the 1960s, when he began to wonder what DXers would do when they had worked all of the DXCC countries. For almost six months, Geoff spent two days each week surrounded by atlases and naval charts, listing, identifying, and grouping islands and archipelagos by continent.

The first IOTA contacts were credited on December 1, 1964, the day the *IOTA Directory* was first published. Today, this award program, consisting of 16 separate awards based on numbers of islands contacted and world location, is administered by Roger Balister G3KMA and the IOTA committee. You can obtain information about IOTA's award program and a copy of the island *Directory* from Roger Balister G3KMA, La Quinta, Mimbridge, Chobham, Woking, Surrey GU24 8AR, England. The price is US$4.00 or 7 IRCs in Europe; US$5.00 or 9 IRCs outside of Europe. ■

A Station T/R Controller

Last month I mentioned a project every QRPer should have in the shack: a station T/R controller. This month we'll take a look at what is needed to accomplish this task.

When I started working on the station controller, I had to design it to work in anyone's station; to be able to mate with and control the vast amount of receivers on the market, without knowing the requirements for muting or antenna changeover. This controller uses relay switching to control the external devices. I chose relays for several simple reasons: They're cheap, easy to come by, and they totally isolate the logic from the external device. I've included a parts list for all major components, with Radio Shack part numbers. Of course, you don't have to get your parts from Radio Shack; junk box parts will do quite nicely. In fact, the board layout is very flexible. You can use either radial or axial capacitors for the two large electrolytic capacitors listed.

To make things even better, I've joined forces with FAR Circuits to produce circuit boards for this column (see the parts list for address).

The T/R controller should be looked at as four different circuits. This will make troubleshooting easier, should the need arise. The four circuits consist of the following: sidetone generator, audio amplifier, delay switching and keying, and power conditioning. To better understand how the T/R controller works, a short description might help. We'll start with the power conditioning part of the controller.

Parts List

1	741 op amp	RS 276-007
1	LM386 amplifier	RS 276-1731
4	2N2222	or RS 276-2009
1	2N3905	or RS 276-2023
4	1N4001	RS 276-1101
1	1N914	RS 276-1122
1	5k PC trimmer	RS 271-217
1	100k PC trimmer	RS 271-220
	or 100k panel pot	RS 271-092
1	10k PC trimmer	RS 271-218
	or 10k panel pot	RS 271-1721
1	4700 µF cap	RS 272-1022
1	1000 µF cap	RS 272-958
	or 1000 µF	RS 272-1047
1	470 µF	RS 272-1030
	or use 470 µF	RS 272-1018
1	0.1 cap	RS 272-135
1	47 µF	RS 272-1027
1	10 µF	RS 272-1025
2	PC mount relays	RS 275-219
1	reed relay	RS 275-233
1	metal enclosure	RS 270-272

Miscellaneous parts include resistors, small capacitors, PC board, IC sockets, connectors, knobs, LEDs, wire, antenna relay (a good choice would be RS 275-218), and other odds and ends.

A blank PC board is available for $6.50 + $1.50 postage/handling from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

Power Conditioning Circuit

Being solar powered, my station is a bit different from the usual ham shack. A large battery bank supplies power to the shack. Because of the nature of this setup, I have to decouple any 12-volt device from the 12-volt bus. In the T/R controller, the decoupling is in the form of a large electrolytic capacitor.

To provide reverse voltage protection to the T/R controller, a small 1N4001 diode is in series with the supply line. You might worry about the diode surviving the inrush of current to charge the capacitor, but this shouldn't be a problem. If you can't sleep at night thinking about it, use a 3-amp diode in place of the 1N4001.

If you connect up the T/R controller backwards, nothing will happen, and there will be no damage. After this diode comes the 4700 µF capacitor. You may not need that much capacitance. In fact, one of the T/R controllers I plan on using in a transceiver has only 2200 µF of capacitance. Use what you need to keep critters off of the +12 volt bus, but don't lose any sleep if you can't find the exact amount listed here. The value is not critical. I supply operating power for the T/R controller from my +12 volt power bus.

As a second thought, you can use a wall transformer to power the T/R controller, as long as the unit can supply +12 volts with at least 500 mA. The large 4700 µF cap will smooth out even the nastiest wall transformer power supply. You may even be able to get by with an AC powered wall transformer, as the diode will rectify this and the 4700 µF cap will then act as a large filter cap. This is not the best route to take, but it *should* work. A 470-ohm resistor and LED are included to let you know the T/R controller has power applied to it.

Four LEDs keep you informed on what is happening with the T/R controller. There is one each for "power on," CW keying, delay, and "audio on." I used TP1 LEDs in my prototypes. These are very bright and look nice in the case I chose to use.

The Sidetone Generator

I used a 741 op amp to generate the tone, with a PC mounted trimmer to adjust the pitch. You can adjust it to your liking. This tone generator is turned on and off to follow the keying. I did not want to keep the tone generator running all the time, since this could cause trouble if the high gain audio stages of a direct conversion receiver were to pick it up. The result would be a constant tone in the receiver. The tone generator is keyed on by applying +12 volts to the sidetone input.

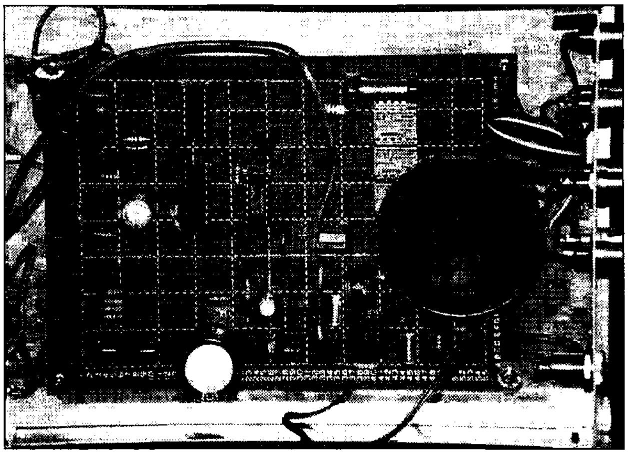

Photo A. Inside of the prototype of the T/R controller. Notice the four relays; one is hidden under the speaker. Also, note the three extra ICs for the keying delay circuit. This was not included in the final circuit.

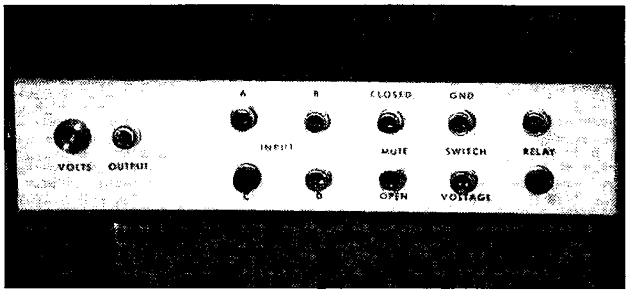

Photo B. Rear view of the T/R controller in a Radio Shack chassis.

The Audio Amplifier

The audio amplifier takes the low-level sidetone and provides speaker level audio. This is a classic design using an LM386 audio amplifier chip. Notice the second 1000 µF capacitor near the LM386. Don't forget to include this capacitor; it keeps the LM386 happy.

You may either use the PC mounted trimmer to adjust the volume of the sidetone, or a panel mounted control, as I did. If you decide to panel-mount the volume control, just run the wires to the PC holes used for the trimmer. Use small shielded cable. A set of holes is included on the board to turn off the audio amplifier. If you want to keep the audio on all the time, jumper these pads together and just turn the volume down. I added this feature just in case your keyer has a built-in sidetone.

Delay Keying

Though the final product is simple, cheap, and efficient, I had to do some real soul searching on the design of the delay keying. In the photographs of the prototype, you'll notice several extra IC chips. These were used to add a 25 ms delay to the transmitter. The idea was to turn the relays on, let the contacts stop bouncing, and then turn the transmitter on. The prototype worked quite well, but I was also getting reports of missed first characters. By the time I fixed that problem, I had practically no delay left, so why include it?

The delay circuit is fast (this depends on the type of relay used) and extremely easy to build. When the key is closed, transistor Q2 is turned on. This supplies +12 volts for several circuits. First, if you connect the sidetone out to sidetone in, you provide keying voltage for the sidetone generator. Second, transistor Q3 is turned on. This grounds the reed relay, keying the transmitter. An LED is also keyed along with the relay.

While all this is happening, +12 volts is applied to the 47 µF capacitor via the 1N914 diode. This turns on Q4 and Q5, activating the two on-board relays. Notice that the contacts of each of these relays are not connected in any particular way. This is one of the benefits of the T/R controller: complete versatility. One relay will control an external antenna relay and the other will mute the receiver. The contacts of both relays are rated at 5 amps. You can use one of the relays, if need be, to control a 110 volt AC antenna coaxial relay. However, if you do this, use EXTREME CAUTION since you'll be exposing yourself to the full line voltage on the back of the board.

You might also want to move the relays off the board. This might be the case if you can't find, or don't want to spend, the money for Radio Shack relays. If this is so, connect the coils to the proper pad of the T/R board. Mount the relay and use the contacts to your liking. A 4PDT relay can be used with no trouble if you don't mind the rat's nest of wires coming from the contacts.

In small QRP projects, you might even be able to get away with running the antenna through the on-board relay. There is minimum RF bypassing

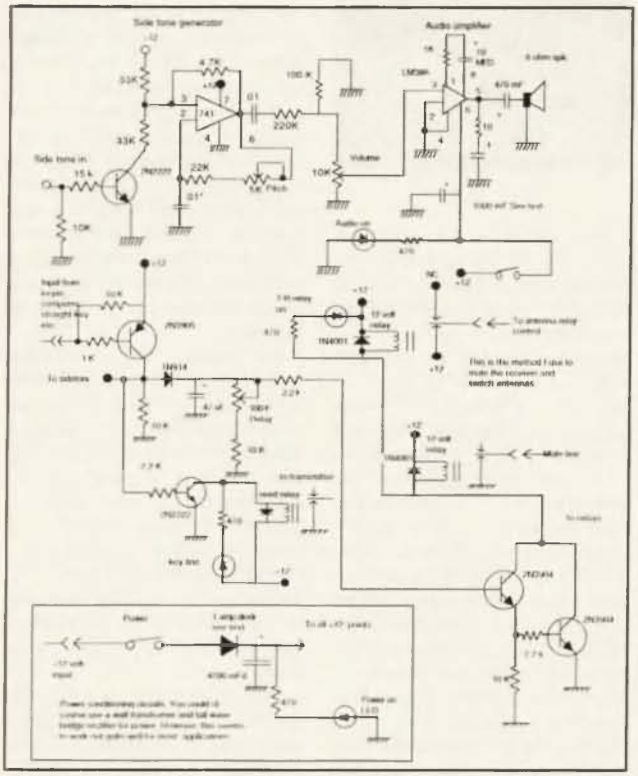

Figure 1. Schematic for the T/R controller.

on the board. You might have to add some 0.01 and 100 pF caps on the input lines to keep RF from getting into the circuit.

Start to Finish

The T/R controller is best built in sections. The first place to start is with the power conditioning components. Stuff the components for the sidetone and audio amplifier second. After checking over your work, connect an 8-ohm speaker to the output terminals. Set both the pitch control and the volume control to mid-range. Apply power to the controller. *Make sure the audio power is turned on via the PC pads.*

If you installed the power-on LED, it should be on. Use a clip lead and apply +12 volts (get this from the + side of the 4700 µF capacitor) to the sidetone in the terminal. If all is working, you'll hear a tone from the speaker. Remove power from the board. Finish stuffing the rest of the board.

Set the delay control to mid-range. Apply power to the board. Ground the key input terminal. The relays should pull in and the T/R LED should be on. Remove the clip lead from the key-in terminal. After a short delay (determined by the setting of the delay control), the relays should drop out and the LED should go dark. Key the terminal on and off with the clip lead. This should make the reed relay also turn on and off, following the keying from the terminal. The CW LED should also follow the keying. Use a small wire and connect the sidetone out to sidetone in terminals together. Again, ground the key input. The sidetone should sound, relays pull in, and reed relay follow the keying.

If you connect your keyer, straight key, computer or whatever to the key in the terminal, grounding this point will turn on the T/R controller. I used a six-position switch to select six different inputs from the front panel on my T/R controller. Not only do you get total automatic T/R control, but the added convenience of keyer selection, too.

Antenna Connection

Perhaps the most difficult part of building the T/R controller will be deciding how to connect it up to the rest of the equipment. Primary consideration will be in the antenna switching. I use a second relay (from the junk box; if purchased, a good choice would be a Radio Shack 275-218) in a small aluminum box. The box is mounted in an out-of-the-way place with a control cable connecting the antenna switching relay to the T/R controller via a two-conductor cable.

This box contains SO-239 connectors and RCA jacks, so I can use both or either type of connector on the end of the cables from the antenna, receiver, and transmitter. The relay contacts switch from receiver to transmitter. The control voltage is +12, supplied from the T/R controller. One of the on-board relay supplies switched +12 volts to the antenna control relay.

The second on-board relay mutes the receiver. My receiver needed the mute line isolated from ground to receive. To mute the receiver, you mute the line to ground. Now you can see why the contacts of the relay have been left uncommitted. I use RCA jacks on the back of the T/R controller, and just pick the ones that I need.

Well, that's about all the space this month. Now that you have a T/R controller, perhaps next month we'll have something to control. Don't unplug the soldering iron just yet.

AEA

The PC-Pakratt II has finally arrived! This program replaces the popular PC-Pakratt program for IBM compatible computers. It is a powerful program that takes advantage of AEA's exclusive Host Mode, and offers full Host Mode support for the latest PK-232 command set. PC-Pakratt II works with IBM AT & XT compatible computers, with or without a mouse. The program includes the latest version of AEA's PK-FAX program, offers a full QSO logging feature and a DOS gateway, and it can save and restore all 18K of PakMail messages to disk. Its other features include user-friendly help screens, macro facility, complete parameter screens, and quick access to the user's word processor. PC-Pakratt II very closely resembles the original program, so current users should find it relatively quick and easy to make the switch.

If you already own the original PC-Pakratt, regardless of when you purchased it, you are eligible for a $40 discount off the suggested retail price of $70 for the new program. For more information contact *Advanced Electronic Applications, Inc., P.O. Box C2160, Bldg. O & P—2006 196th SW, Lynwood WA 98036-0918; (206) 775-7373, Upgrade Hot Line: (206) 774-1722.* Or Circle Reader Service No. 201.

ASHTON ITC

Ashton ITC has announced a new communications software product called SCORPIO (Shortwave Computer Operated Radio Plus Input/Output). Designed for the sophisticated shortwave listener and monitor, SCORPIO breaks new ground by combining intelligent scanning, based on a flexible database search, with simultaneous automated digital signal decoding and data capture. It can be interfaced with ICOM and Kenwood computer-ready receivers, plus RS-232 all mode terminal units such as those manufactured by AEA, Kantronics, MFJ, Tonno and others.

SCORPIO makes it easy to build databases (log files) which can Include a received station's identification, location, frequency, mode, time of operation, agency or type of service, signal level, date heard and any pertinent remarks. These databases may contain thousands of entries and may be sorted and searched by any category. An *AutoLog* function can even record "hits" to disk during a scan, and convert the resultant file to a database.

SCORPIO includes a comprehensive User's Guide and a sample database containing 100 of the most popular HF utility and SW broadcast frequencies. It sells for $90. Contact *Ashton ITC, P.O. Box 830, Dandridge TN 37725; (615) 397-0742.* Or circle Reader Service No. 205.

J•COMM

J•Comm has introduced a new audio filter for use by amateur radio operators and SWLs, the MagicNotch™. This is an automatic audio notch filter designed to instantly remove heterodyne QRM from SSB reception. It effectively reduces interference caused by negligent operators tuning on or near the frequency, CW signals,or other carriers. The MagicNotch filter is also very useful in reducing the effects of computer generated RFI, which is becoming an important source of heterodynes in the ham shack today. No tuning of the filter is required. When interference of a constant frequency is detected by the control circuitry, the internal switched capacitor active filter (SCAF) is automatically tuned to that frequency, effectively reducing the interference by up to 40 dB. The filter will continue to track any variation in the frequency of the interference until it disappears. The width of the notch is extremely narrow so there is no noticeable degradation in the quality of normal speech signals. The filter activates in less than one second. In many cases, the operator may not even be aware that a carrier has appeared. Operation of the filter is indicated by a two color LED which turns red when an interfering signal is locked in.

No modifications to existing equipment are necessary. The filter operates on the audio output from the receiver as obtained from the external speaker output. The built-in 2 watt amplifier is sufficient to drive any 8 ohm speaker. The filter is powered by 10–14 volts DC, which is usually obtained from the accessory connector of the rig. The compact 5.5" x 3" x 1.5" unit is housed in a gray and blue aluminum enclosure.

The introductory price is $100, plus $5 S&H. Contact your nearest dealer, or *J•COMM, P.O. Box 194, Ben Lomond CA 95005-0194; (408) 336–3503.* Or circle Reader Service No. 203.

AMERICAN DESIGN COMPONENTS

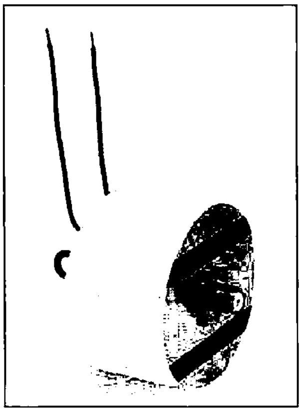
A new 1991 catalog of electronic, electromechanical and computer-related parts and components at below factory outlet prices is now available from American Design Components. This 48-page, fully-illustrated catalog is chock full of components and peripherals. It features integrated circuits, switches and connectors, power supplies, rechargeable batteries, fans, blowers, and more. Easy indexed for shopping, the catalog also features a large assortment of computer products such as monitors, disk drives, add-on boards, mice, modems, and unbelievably low-priced computer systems. All material is available for "off-the-shelf" delivery.

Contact *American Design Components, 815 Fairview Avenue, Fairview NJ 07022; (800) 776-3700, (201) 941-5000.* Or circle Reader Service No. 204.

PALOMAR ENGINEERS

Palomar Engineers has a new addition to their high power balun line: the Model SB-4. This balun, 4" in diameter x 4" high, is specially designed to operate at high SWR so it can be used in antenna tuners, at the feedpoint of multiband dipoles, and to convert from ladder line to coaxial line outside the hamshack. It has a 1:4 impedance ratio and operates efficiently from 1.8 to 30 MHz. Power capability is 2000 watts continuous power at up to 10:1 SWR. The balun is weatherproof, epoxy-filled and sealed, with Teflon™-insulated SO-239 connector and wire leads for the antenna or ladder line. A stainless eyebolt is provided for mounting.

The Model SB-4 is priced at $75. Contact *Palomar Engineers, P.O. Box 455, Escondido CA 92033; (619) 747-3343, FAX (619) 747-3346.* Or circle Reader Service No. 202.



PASTERNAK ENTERPRISES

Pasternak Enterprises catalog #1991 features a complete line of amplifiers, molded breakouts, coaxial cable, coaxial switches, cutting tools, stripping tools, coaxial connectors, coaxial adapters, coaxial detectors, coaxial attenuators, coaxial terminations, patch cords, programmable attenuators, push-button attenuators, coaxial cable assemblies, waveguide adapters, twinaxial adapters and connectors. In addition, this catalog contains many new cable assemblies that utilize 3.5mm, 7mm, HN, N, SMA, SMB, SMC, BNC, TNC, UHF, SC, SHV and MHV connectors. It includes pricing on more than 2,500 standard catalog items, as well as technical information.

For more information contact *Pasternak Enterprises, P.O. Box 16759, Irvine CA 92713-6759; (714) 261–1920, FAX (714) 261–7451.* Or circle Reader Service No. 206.

Why Rigs Sound the Way They Do

One favorite topic you can hear on any ham band at just about any hour is the good ol' "How's my rig sound?" Sometimes it seems like an obsession, surpassed only by the local weather and OTH.

Why are we so concerned about how our radios sound? Well, for one thing, it comes from the tradition of home-brewing. Remember, there was a time, not all that long ago, when we hams built our own stations. Not only was the transmitted audio quality a point of pride, it was also a legal concern. Bandwidth limits had to be observed, and you couldn't count on Kenwood to ensure you weren't breaking the law because of excessive high frequency response or distortion.

Today, of course, home-built stations are rare, at least on this side of the now-rusty iron curtain. Yet we continue to discuss and adjust our audio, trying different mikes and level settings, all the while striving vainly for that "perfect" sound. What we often overlook, however, is that the sound of a rig is dependent upon far more than its microphone, and in fact may be inherent in the radio itself. More than anything else, the modulation mode (AM, SSB, FM) and the method used to achieve it determine the limits of audio quality. But let's start where the audio signal starts: the mike.

Speak Into the Transducer, Sonny

Yes, your microphone's characteristics do have a great influence on your audio.

There are four types of mikes in common use:

Crystal mikes depend on the piezoelectric effect to generate a voltage by flexing a crystal. They have a high impedance (50k ohms or more) and are mostly found with older tube gear. The mikes are somewhat tinny and harsh sounding. Sometimes, the effect can result in excellent "punch" on SSB. Unfortunately, crystal mikes also have a limited life, and the old one you got with that hamfest special may be shot. The symptom of a bad one is *extremely* tinny or distorted audio, bordering on the unintelligible. Many an hour has been lost fruitlessly tracing signals through perfectly good audio stages when the real problem was a bad crystal mike.

Ceramic mikes are similar to the crystal units except that they are less likely to fail with age, and they are a bit less tinny. Although not in common use, they can be great with tube gear, and even used successfully with solid-state gear, as long as there's a matching transformer between the mike and the rig. Some exotic headset-type mikes use ceramic elements to great advantage.

Dynamic mikes are built somewhat like small speakers. They have permanent magnets and voice coils. The difference is that they are used in the generator mode; the output from the voice coil results from the sound waves striking the diaphragm.

These mikes are inherently low-impedance, and produce far less output than their piezoelectric cousins. Some have small matching transformers in their cabinets for high-impedance use. Dynamic mikes are pretty rugged, and rarely ever fail.

Their sound is quite a bit less tinny than that from the crystal or ceramic types, but it still has a rising frequency characteristic. That is, the voltage output of the mike rises with the audio frequency. Until a few years ago, mobile HF rigs and most VHF units came equipped with dynamic mikes.

Electret condenser mikes have the smoothest frequency response of all. They use a permanently-charged diaphragm (the "electret") between two electrodes, in a capacitor-like arrangement. The minute changes in capacitance which result from the diaphragm's flexing can be detected with an FET preamp and converted into an audio signal. In fact, most condenser mikes have the preamps built right into their tiny cases! Even with the circuitry, they are the smallest mikes around. Because their diaphragms don't have to push against anything, they don't need much mass. (That's also the reason for the great frequency response.)

Because of their flat frequency response, these mikes sound very natural, and high-precision versions are often used in studio recording. Natural voice quality is not the same thing as maximum intelligibility, though. In fact, a somewhat tinny mike gets through HF QRM better than a natural, smooth condenser mike. Despite this, most new rigs come with condenser mikes because they are small and inexpensive. With some equalization, though, they can sound fine on the air. Some radios incorporate the EO into their speech amps.

By the way, all condenser mikes require DC power to run the preamps. Some have small batteries, but many are supplied with power from the rig, often on the same wire carrying the audio.

XMIT Modulation

Different modulation modes sound different. We all know that, but why is it so?

In theory, modulation is modulation, and it shouldn't make any difference what kind you use, as long as the received signal levels are adequate to prevent noise on the demodulated output. But you've heard it said that FM sounds the best, AM is great, and SSB is the worst. Is this true? Well, yes. Also, no.

FM does sound great. Most FM rigs, including HTs, are supplied with condenser mikes, so they start with natural voice quality. FM modulators and demodulators can be made very linear, which means low distortion. Also, the inherent noise-canceling effect of FM makes it seem especially clean, and the punch of a tinny mike is not needed. (In fact, excessive high frequency response makes a noisy, weak FM signal even worse, since it dilutes the tiny signal energy across a wider bandwidth.)

Finally, the IF bandwidth in FM receivers is quite a bit wider than the transmitter's deviation bandwidth, and unlike AM and SSB, it is not directly related to high frequency response. As a result, the receiver's selectivity filtering does not degrade the audio. Altogether, there's not much to interfere with the quality of FM, at least under local conditions. (Multipath and fading distortions make FM a dicey proposition for HF, although it is still fun.) If you were allowed 15 kHz audio bandwidth and wider deviation, you could sound just like your local rock and roll station.

AM. Ask any AMer and he will tell you that AM sounds much better than SSB. Is this true? Yup, but it doesn't have to be. Recently, I had the opportunity to play with the new Kenwood TS-950S HF rig, which has the facility to allow receiver filter selection independent of mode. I tuned an SSB signal in, and it sounded normal. Then I *removed* the SSB filter, and wow, it sounded exactly like AM—much crisper and brighter and altogether more pleasant. At last I could confirm what I'd always suspected: The deficiency seemingly inherent in SSB is actually caused by the sideband filter. (More on this later.)

The AM mode is simple and easy to do. In order to avoid having to make all the transmitter stages linear, though, modulation is usually accomplished right at the finals, by means of feeding their DC power through a transformer and pumping audio into the other side. The power fluctuates, and so does the output power, and there you have it—AM.

Of course there is always some audio phase distortion with a transformer, but it is negligible by voice communications standards. And without a sideband filter, the high-frequency rolloff can be rather gradual, resulting in considerably more than 3 kHz audio bandwidth. It's illegal, but it sounds real nice. So, AM is pretty darned good. But then, the amount of received noise is usually greater than with FM, so it sounds a little less clean.

And then there's selective fading, when one sideband fades more than the other, causing horrendous distortion. AM is especially prone to this kind of problem, because it includes and demodulates both sidebands. You can avoid it by clipping off one sideband, but then you may as well just go to SSB, because the clipping filter will make it sound the same.

SSB—is it bad? No, not at all. It is far and away the most power-efficient mode, and the audio is adequate for our normal uses. But it does sound a bit odd, even when the signal is precisely tuned in. To me, it sounds constricted. Of course, the filtering does cut the high frequencies off rather steeply at 3 kHz, which is required by law anyway. (Are you listening, AMers?) But it's more than that.

It appears to come from the resonance of the sideband filter. Any such steep filter will ring a little bit, and in some rigs you can hear it by tuning in background noise with no signal. If you listen carefully, you can discern a definite pitch to the noise, and this pitch is the resonance of the filter. Switch to AM and the note will be gone.

Remember that the sideband filter is used both in transmit and receive, so its effects are doubled. Is there another way? Yes, there is, and it is actually older than the way we do it now. Early sideband rigs used a technique called "phasing" to generate and receive SSB. In this method, transmit and receive signals at the IF level were split 90 degrees out of phase and combined in a special sort of mixer to cancel one sideband. It worked fine, but it was tricky to align and required lots of components.

Also, the phase relationships had to remain constant over the required bandwidth, or insufficient alternate sideband suppression and/or distortion could result. The great part of the scheme was that there was no sideband filter. At the time, the prime considerations were cost and availability—the ordinary parts were cheaper and easier to get than a good steep filter. What no one even realized then was that the technique held the promise of sounding better than a filter. Unfortunately, phasing rigs have disappeared as good, inexpensive filters have dominated the scene.

Is it too late for phasing? Maybe not. With today's technology, good and stable phasing circuitry should be simple to accomplish. Then, the IF filtering could be better tailored to avoid that tight, almost-ringing sound associated with SSB.

SSB Filter Adjustment

If your LSB and USB don't sound the same, your rig may need adjustment. They should have approximately the same tonal balance. An easy way to check is to let the rig warm up for about 15 minutes and then tune to where there is only band noise and no signal. Switch between the two sidebands and note the sound. They are not likely to be exactly the same because the two skirts of the sideband filter are never perfectly symmetrical. If the two sound *very* different, one or both may need adjustment.

Check the service manual for the carrier oscillator adjustments. These determine the exact frequency of the signal sent through the filter, and there is one for each sideband. Turning them will vary the audio response from tinny to bassy.

Incorrect adjustment can result in poor adjacent sideband suppression on both transmit and receive, so it is important to set them carefully. The manual should detail the correct procedure.

Well, that's about it. See you all next month. 73

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D. WA3AJR
6 Jenny Lane
Baltimore MD 21208

CoCo Packet

Here in Maryland, February is the month with the reputation of blessing us with the most snow of the winter. So, as I sit here looking at my beautiful doublet antenna that took me so long to get up, as it now lies frozen on the ground, let's have a look at what interests you.

Michael Simmons WB9CWE of Charleston, Illinois, relates being an avid reader of "RTTY Loop" who has a special interest in the Tandy Color Computer. He states that to his chagrin, he has noticed a painful lack of packet software for the CoCo. He is wondering if there is any source, commercial or public domain, for packet software for this computer.

Well, Michael, my search for packet software reaches back many years, and I will say up front that I have often been as frustrated as you are. Several years ago, noticing that some of the original work on digital modes was done on Motorola (6800 and offspring) microprocessors, I wrote to several of the pioneers, asking them if software applicable to the masses would be in the offing. To a man, they responded, "No."

It seems that, all things considered, most of the applications for general purpose (not dedicated) microcomputers were just not suited to packet or AMTOR as configured, usually because of hardware constraints. This is not to say that someone, somewhere, did not write a program to put the 6809 (the CoCo's CPU) onto packet; it's just that no one told me about it.

As it sits now, the best bet for packet is to use your computer as a powerful terminal, with one of the many terminal programs, and allow a dedicated microprocessor in a box, a packet terminal, to do the hard part. That way, you can have the best of both worlds.

Oh, yes, one other point Michael mentioned in his letter. He asked if it were possible to convince ham radio software writers to give some serious attention to writing communications software for the CoCo. Michael notes that this computer has evolved into a rather sophisticated machine with full features, making the lack of support by the various commercial software publishers very puzzling.

Puzzling? Not if you consider the size of the installed base of computers among radio amateurs. Again, I queried some of the software houses, and that is exactly what I heard. Yes, the CoCo is a fine machine, but the fact remains that there are more C-64s and PC clones in ham shacks than CoCo's. There are several public domain or shareware programs, but, as you know, essentially no commercial ones. A company just cannot afford the development and marketing costs of a program that may receive only limited support from the community.

Hope the information helps. Who knows, maybe one of our readers will roll up his sleeves and write that program!

Copying and Receiving CW

Norm Boles WJ5Z of Las Cruces, New Mexico, is particularly interested in copying CW on his computer. Again, Norm, I have looked and found nothing. There are several CW practice programs around, and in fact, such a program is relatively easy to write in BASIC. Yes, if there is a demand I will print one here, but only if more than one of you asks for it.

Receiving CW is another matter. I agree that the CoCo is well-suited to the task, but no one has written the program—yet! If I hear something, you can be sure I'll pass it along.

The Mighty Mite

From the newest to one of the oldest—machines, that is—I have another letter here from Bob Schaumleffel WA2IKS, of Olean, New York, who speaks to my recollection of the Mighty Mite printer. Bob seconds the comment that this machine, if you can find one, is a beast to align but a workhorse once it is.

He purchased one about six years ago, complete with manuals (now that's a find), went through the alignment procedures, and found that if an adjustment was off a few thousandths of an inch, the little feller wouldn't work properly. He finally got it to perk along, and it is still in use today as one of his hard copy machines.

Bob also feels that if you plan to get a Mite working, it's not a bad idea to pick up a junker at a hamfest. Parts are hard to come by and any source wouldn't hurt! Thanks for the letter, Bob. Notes from youngsters like you keep us all hopping. And thanks for the stamp on the letter. It's been quite a few years since I've seen the 5 cent amateur radio stamp. That I'm old enough to have some put away, and remember when 5 cents was first class postage, is frightening enough!

Solder Sniffer Award

The RTTY Loop 1991 Solder Sniffer award candidate this month is Rob Zahora of Burlington, Massachusetts. Rob writes that he has finished the TU-1000, published in the June 1985 issue of *73*. Now, as soon as he gets a Baudot to ASCII conversion board, he should be in business. Hey Rob, please let us all know how things work out.

PK-232 Quirk

A cautionary note arrived in the mail from Bill Weatherford WA0NDF/TU4CQ, Cote d'Ivoire. Bill is using the AEA PK-232 with his Leading Edge Model D computer, and a friend of his is also using a PK-232 with an Apple II+. Both of them are quite pleased with the PK-232, but noted an interesting quirk.

Like many "boxes" which come into the shack these days, the PK-232 does not come with a power supply. Bill points out that the manual for this terminal calls for 12 volts DC at 1 ampere on one page, and at 750 mA on another. He found that if you run it at a tad less than 750 mA, you get all sorts of weird results. To stay on the safe side, be sure to use a power supply that can supply the full ampere. A marginal supply just won't do here. Thanks for the tip, Bill.

Problem of the Month

This one comes from Leslie Bruce W0OX (ex-W9BSR/W7KMD/W0EHX/K5AXW) of Boulder, Colorado. Leslie states that after many years of Model 14s, 19s, 28s, 33s, and 35s, he is now all computerized, and he hopes to obtain hard copy from his computer printer while using the computer on RTTY.

With a C-64, Hamtext cartridge, a Flesher TU-170, and a Blue Chip printer, Leslie wonders if there is a way that he can print on the printer both the transmitted and received data while using the split screen display of Hamtext. I don't know, but if the manual does not say so, I will guess that you can't. There are enough others out there with similar setups, so if it's possible, hopefully I will hear about it soon enough. If so, I'll pass it along here in "RTTY Loop."

On another note, Leslie wonders what his Blue Chip printer looks like to other programs. With printer drivers like Epson, Gemini, Panasonic, Silver Reed, Okidata, etc., there is no mention of Blue Chip. Well, to the bast of my knowledge, the Blue Chip is one of a series of printers which emulates the Epson MX-80/FX-80 standards. I would call it an Epson, and hope for the best.

Good luck, and I hope to hear from you again. I'm glad the years have not blunted your initiative in this crazy hobby of ours.

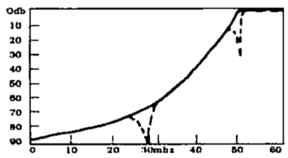
Get in Touch

As always, I remain available to your thoughts or such via mail, at the above address, or on CompuServe (ppn 75036,2501) or Delphi (username MARCWA3AJR). I love hearing from you, and you never know when your obscure question will end up here in print for everyone to see!

Next month, don't miss *73* as "RTTY Loop" Marches along. (Sorry... I couldn't help myself!)

DEFENSIVE FRONT LINE

PERFORMANCE CHARACTERISTICS



SOLID LINE — MODEL 430
DOTTED LINE — ADDITIONAL ATTENUATION OF WAVETRAP MODELS

SPECIFICATIONS:

IMPEDANCE:	75 OHMS
CONNECTIONS:	"F" FITTINGS STANDARD

437	(WITH 2M WAVETRAP)	$17.95

Over a thousand users in North America and Europe have enjoyed good results in tackling their TVI problems with I.C.E.'s wide line of 75 Ohm High Pass Filters.

Model 430 Series offers the only complete engineering design in the industry - common mode interference isolation and blocking, shield electrification choking, differential interference filtering, lightning protection isolation, and a standard I.C.E. 1/8" thick heavy chassis enclosure with grounding feature and stainless steel hardware - all in one 2" x 3" unit at easily affordable prices.

High pass filters offer a clean, inexpensive way to block frequencies below 50 Mhz. emanating from nearby transmitters from disturbing TV and VCR sets. Units are easily mounted or hung from appliance rear side close to antenna terminals and work with VHF/UHF/FM/CATV operations. 75 Ohms. "F" connectors standard. Wavetrap models have additional componentry to attenuate signals from specific interfering sources as well as below 50 Mhz.

Individually boxed with mounting hardware, manual.

Meet Peyton Montcure

In the October issue we interviewed Tom McMillan WB3HGW, the man responsible for the FCC decision to relax CW testing standards in upgrades for the handicapped. In the December issue, we interviewed April Moell, a professional occupational therapist who uses amateur radio in the rehabilitation process. Now we come to the other end of the spectrum. To a man who feels that no handicapped person should be required to pass any form of Morse code test for a ham ticket anywhere in the world. So emphatic in this quest is law student Peyton Montcure that he has taken his demand to the United Nations, and he may soon take the United States to court.

What follows is the transcript of an interview that aired during last summer's second "No-Code National Teleconference Radio Net." Montcure was interviewed by *Newsline* correspondent Steve Bauer KCØHF. Ironically, being blind, Bauer himself is a handicapped person.

From the No-Code Teleconference

Bauer: Who is Peyton Montcure and how did he become interested in amateur radio?

Montcure: I became interested in ham radio years ago when a ham radio operator came to my house when I was still a child, and gave me a little introduction. I was very interested in it—but I couldn't use a telegraph key. I found that I simply couldn't coordinate my muscles so that I could get any sort of rhythm or speed. I gave it up and forgot about it and went on with my life.

Since then, I went through college and my learning disability was diagnosed. I found out, for example, that I cannot use a manual typewriter, but I can use an electric typewriter or a word processor. Again, it was the same problem with physical coordination.

I went to law school and began to get very interested in issues related to the handicapped. One day I thought that I would write to the FCC—because I had some time and I thought it would be fun to get into ham radio. I had recently attended a talk that a ham radio group held suggesting that people might like to get involved in it. Much to my surprise, and indeed shock—because I thought that so much progress had been made regarding issues for the handicapped—I found that the FCC would not even accept my complaint!

They did not even appear to know what a civil rights complaint was. They didn't want to waive the code for me or anyone. But I managed to work my way up the chain, finally writing a letter to President Bush, and getting the FCC to accept my civil rights complaint.

They have since rejected it, which they are entitled to do, giving as a reason that the Americans With Disabilities Act of 1989 has not yet been passed by Congress. But of course it will be. As soon as it is passed, I will file another civil rights complaint. Either the FCC will change its rules so that the code will be waived for the handicapped, or I will end up filing another complaint.

After all, the object is to integrate the handicapped into American society, and one of the best ways to do this is to get them fully into transportation, and in this case, communications.

Bauer: The commission has recently announced that a handicapped applicant—after passing a 5 word per minute code test—with proper medical certification will not be required to pass additional code tests. Does this change the FCC rules enough to basically satisfy your need and make you happy?

Montcure: No, this does not satisfy me or make me happy. The FCC apparently has a battle going on internally as to whether they are going to keep the code or not. The point at issue here is this: If I am in a wheelchair outside the FCC building and want to get inside, would they tell me that I have to get up out of my wheelchair and struggle up the steps at 5 or 20 steps per minute? Why can't I use the ramp? If I am handicapped and cannot use the code at all, why should I have to learn it? It just does not make sense.

Bauer: What about the theory part of the test? Should that also be waived for anybody that claims a disability in that area?

Montcure: I can't see what sort of disability would necessitate waiving any other part of the test. A civil rights official would really need to deal with that issue. If somebody could present information proving that they could not handle some particular part of the test, maybe some modification to some other part of the test would be appropriate. I frankly cannot imagine any problem there, because we are certainly not talking about any physical handicap.

Bauer: How would you respond to a handicapped person who had passed a code test, and who challenged you on your particular views regarding the handicapped and code testing?

Montcure: I would first congratulate them on being able to pass a code test or use a manual typewriter. But handicaps do vary from individual to individual. Some can do it, and some can't!

If you can do it, fine. But the object here is to arrange for the handicapped to communicate like everyone else, and not to restrict them by some arbitrary or capricious standard, such as using a key which is irrelevant to voice communications.

Bauer: Let's assume that you have passed the state bar and you are a practicing attorney. How would you feel if the firm you were working for hired someone who used their handicap to get out of taking 50% of the courses you had to pass in order to become an attorney?

Montcure: It would depend on the particular courses. Certainly I would want them to take the courses that are necessary to practice law, but if the Board of Bar Examiners also required the individual to run a marathon, and then swim, and canoe, and do certain other physical exercises, I would not see any sense in that. In other words, each separate test must have a reason behind it that justifies it, and that justifies excluding individuals who cannot pass it. The code test simply does not meet that test.

Bauer: But you may get on the air and never have to figure out an Ohms Law formula! I guess what I am trying to find an answer to is where do we stop cutting? Where do we stop diluting the requirements for not only amateur radio but for other things?

Montcure: In the language of the 1973 Rehabilitation Act that Congress passed, the question was whether the handicapped person is otherwise qualified. I cannot see how someone who did not know electrical theory could be qualified to operate a ham radio station. That is very important to the operation of amateur radio gear. And I can understand, for example, that the FCC might like to pass a law saying that people who cannot operate a code key, and who do qualify without learning the code, are absolutely forbidden from using a code key, by law!!

Bauer: When the FCC formalizes their new proposal concerning waiving upgrade CW tests for handicapped persons, will you try the 5 wpm test yourself?

Montcure: I expect that the Americans With Disabilities Act will be passed by Congress very shortly, and that requires accommodation in communications. As soon as that bill becomes law, I intend to file another civil rights complaint, and I imagine that the code standard will be done away with for those who cannot operate a telegraph key.

Naturally, it it were found that I or some other handicapped individual could manage the key in order to broadcast, that would be fine. But five words per minute is absurd!

Bauer: Have you done any studying for the theory part of the test?

Montcure: I certainly would not want to start studying for the thing until I know that I will be permitted some day to operate ham radio. I shall not start studying until at least the Americans in Disabilities Act passes, or until the FCC decides the complaint in my favor.

Bauer: What class of license would you go for?

Montcure: I would only be interested in a fairly basic license. I suppose in future years I might decide that I want to go for a higher class, but I am just a beginner and when you are a beginner you want to start at the beginning.

Bauer: Thank you for your time.

[An audiocassette of Steve Bauer's interview with Peyton Montcure, edited for air over repeaters and on nets, is available for $5.00 postpaid from The Amateur Radio Newsline, *Editorial Office, at my address at the top of this column. Prepaid only. No COD or credit cards.]*

> ***"I can understand . . . that the FCC might like to pass a law saying that people who . . . qualify without learning the code are absolutely forbidden from using a code key, by law!!"***

Epilogue

About a month after Steve Bauer interviewed Peyton Montcure, Congress passed the Americans With Disabilities Act. A week later, in a nationally televised ceremony, the bill was signed into law by President George Bush. This has opened the way for Peyton Montcure, and possibly others, to again challenge the need for handicapped applicants for amateur licenses to pass a Morse code test al any speed.

It's not the job of "Looking West" to pass judgment on the issue. Rather, that is for each one of us to do individually. What we have tried to do these past several months is to provide a good cross-section of the views. Now it is really up to the FCC, and possibly the federal courts. Only time will tell.

Next Time Around

"Looking West" will be back in April to discuss the rights of repeater users. Just how much power should users have over the way a repeater is run? One California coordination council says that the time has come to recognize the users of repeaters as the supreme beings, and in doing so, they may have relegated repeaters to ham radio public utilities, and their owners to becoming unpaid service providers! Join my guest co-writer, Rich Yarigian N6PVP, as we explore this issue . . . de WA6ITF

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Never Say Die

Continued from page 4

free passes for the vendor area. And then they were even angrier when some of their booth salesmen sneaked into the paid area, got caught red-handed buying equipment, and were thrown out when they still refused to buy tickets. How outrageous of Ham Com to stand up to these bullies! I don't recall that ever happening before.

Hey, That Was A Great QSO!

When's the last time someone told you that? How about it? Have you settled Into a rigid, boring format with your contacts? How'd you like to have the hams you talk with disappointed when the contact is over and eager to talk with you again?

The fact is that you can become an absolute charmer over the air. It's easy. You're just going to have to break a lifelong bad habit. And the best part is that the better you are to talk with, the more fun you're going to have. It's a win-win situation.

Obviously you're going to have to make some changes. Well, you know for sure that the way you've been going about making contacts hasn't worked well. Oh, sure, you've been swapping signal reports and stuff. But how many really fascinating contacts have you had recently?

Am I about to divulge some great secret? Some key to the hidden, almost completely untapped wealth we have available to us in amateur radio? Yep! That's about the size of it.

Let's go about this logically first, then we can go into the nuts and bolts. We'll start with the most basic question: Who is the most fascinating person in the world to the ham you're contacting? Clue: It isn't you. Revelation: It's him!

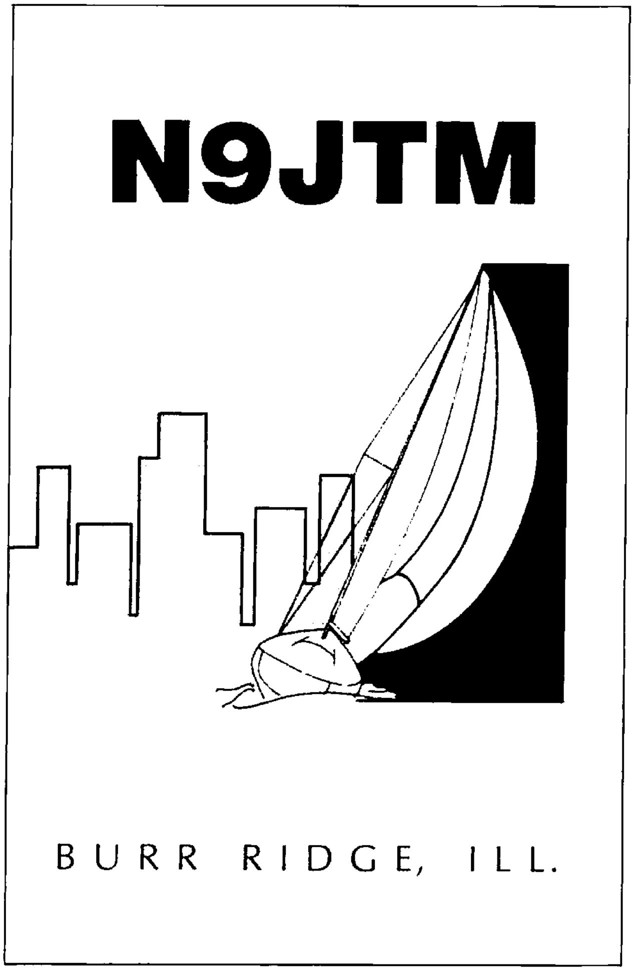
Now, a note to women's libbers, who have been working industriously to louse up the language: What few women hams we have do not need any help with spiffing up their contacts. Merely being women will make them interesting to men. My comments here are meant for men, who are the ones with the problem. You know, I haven't heard a YL on the air in months! Where are they? (I'll tell you later.)

Sorry for the diversion, but I knew that as soon as I mentioned "he" for a ham, I'd have a flurry of furious letters from militant YLs. I wish they'd spend more time on the air and less angrily fighting for their "rights." If we had more YLs on our bands I wouldn't need to write about how to have more interesting contacts.

Okay, I've established the obvious: The most interesting person in the entire world to the chap you've contacted Is him. Thus it follows that the more you can get him to talk about himself, the more he's going to enjoy the contact.

In case you're not following my message, your usual recitation doesn't cut the mustard. He really doesn't give a damn what rig you're using. He won't be amused by your weather, town, antenna and so on. Whoo, that sure cuts down on your transmissions, doesn't it?

If you aren't going to babble the usual dreadfully boring drivel, what can you talk about? How about mentioning what kind of work you do and then ask him what he does . . . or perhaps what he did before he retired? There are many questions you can ask that will open the floodgates.



QSL of the Month To enter your QSL, mail it in an envelope to *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL of the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not in envelopes cannot be accepted.

How did he get involved in amateur radio? Are his kids hams? Why not? Has be ever gone to the Dayton Hamvention? What other aspects of the hobby has he tried? Start making a list of questions which you've found to get the conversation going and keep it by your log.

Step two is to keep your log in much more detail. Make notes on what your contact is telling you so the next time you contact him you'll be able to recall the conversation and carry it on from where you left off. Your best bet here is to use a computer. Second best is to use paper, with a dedicated separate sheet for every contact. Don't try to cram it on a 3" x 5" card. Not even a 4" x 6" card. Go wild and use a whole sheet. Put the call in the upper left hand corner and keep your contacts by call in a file folder close at hand.

You'll get me talking if you ask about some of the countries I've operated from. Or about some of the exciting times I've had on the air. Or the interesting hams I've known. Or my first hamfest (1938). I've had some great adventures in my hamming . . . even some close calls with death. How about you?

Men Don't Talk Much

There is a basic difference between how men and women communicate. It starts when they first learn to talk. Boys play with each other. Girls ditto. The differences in their communications are basic and biologic. Boys are basically adversarial and girls aren't. Alas, most men never learn to actually talk with their wives . . . and vice versa.

With men it's our egos on the line with every contact. With women it's their hearts on the line. We want to see who's best and they want to be loved, putting it bluntly. Having been brought up from year one like this, it takes some serious habit breaking to change. Is it any wonder we have so few YLs on our bands?

Maybe you've noticed that men tend to make a contest out of anything and everything. How many countries we've worked is a measure of our masculinity. How many counties, certificates, how we do in operating contests, how big our rig, our antenna, how elaborate our mobile rig, etc.

They don't call the Cadillac the answer to America's inferiority complex by accident. We're trying to cope with feelings of inferiority with bravado and big signals.

DXers are well aware that DXCC is a serious threat to our hobby and could wipe it out at WARC. But egos are on line here, backed by millions of dollars in monster antennas and multi-kilowatt amplifiers. These DXers have no interest whatever in talking with anyone. They want a card. They need a card as badly as a crack addict needs a fix. And they'll spend whatever it takes to get the card.

There are a few ops in rare countries who have been making a happy living off these egos. They sort out the "green stamps" in their daily mail. I am old enough so I can remember when hams used to send a dollar to assure a QSL. Now anyone really wanting a DX QSL wouldn't consider less than a $20 bill. Some tell me they send $100, "just to be sure."

I've told you about the DXpeditioner who bragged about clearing over $50,000 a year tax-free in such "donations." And that was 30 years ago, so that's more like $500,000 in today's dollarettes. It's almost enough to get me to retire and do some traveling.

I'm Listening

Yep, I'm going to be listening to see if you are able to change your ways. Will you start asking questions and listening, or are you going to keep right on just "broadcasting" the same old tripe? Unless you can get started actually communicating instead of egoing yourself all over the world, the bands are going to keep right on being a dreadful bore.

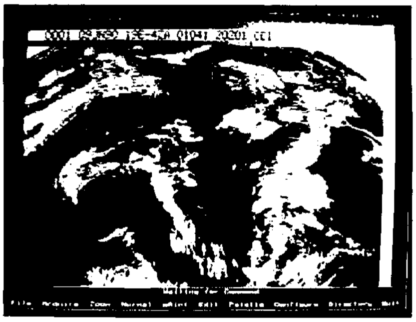
Now I'll see how many readers write that they don't always agree with me. If you disagree, let me know why. And I want a well considered response, not an angry, ego-driven one. Who knows, we might eventually even be able to talk with YLs over the air!

Did you see *When Harry Met Sally*? Well, rent it. Billy Crystal explains why men and women can never be friends. It's humorous, but it's true, too. Can we men, after being trained from birth to be the way we are, ever change?

No Code—At Last!

Okay, it's here . . . finally! The FCC took the easy (and clever) way out. They merely eliminated the code requirement for the Tech license. If 2m doesn't turn into a CB-type mess in days, thousands of old-timers are going to be terribly red-faced, since that's what they've been saying would inevitably happen.

What change will this make? Firstly, it will remove the last feeble excuse kids have for not getting a ham ticket. And I'm talking major feeble here, considering that people who use the *73*



Quorum introduces the first totally integrated system for the reception of weather satellite images directly on your personal computer. Selection of HF NAFAX, GOES WEFAX, GOESTAP, METEOSAT, NOAA and METEOR APT (including satellite downlink frequency selection) are made under complete program control from your PC keyboard.

The easy to learn and use Menu driven program allows you to capture, store, retrieve, view and print images with a few simple keystrokes. Images can be colorized from a palette of up to 262,000 colors when using a VGA display

System configurations capable of NAFAX reception start at $599.00 while fully capable systems can be configured for $1500 to $2000.00, providing professional quality at low prices

For complete information and a Demo Disk, call or write:

Quorum Communications, Inc., 1020 S. Main St. Suite A, Grapevine, TX 76051 (817) 488-4861. Or, download a demo from our Bulletin Board by calling (817) 421-0228 using 2400 baud, 8 data bits and No parity.

Receive Weather Satellite Images and Charts on your PC with Quorum's Totally Integrated and Affordable Weather Facsimile System

CIRCLE 24 ON READER SERVICE CARD

code system can usually master 5 wpm in a couple hours.

Is this marvelous rule change going to bring us the 50,000 new hams a year the ARRL promised they'd provide? I laugh. My view: If we stood on a corner in New York and tried to give away ham tickets we couldn't do it. The general public no longer has the vaguest recollection ot what amateur radio is. We've so totally avoided promoting our hobby for the last 25 years we're now almost invisible.

With no 5 wpm code test for Techs I believe we'll find that those we are able to interest in going on to General will be able to learn 13 per much easier. Those few hams who have started right out at 13 wpm and avoided slower speeds have been able to master the code in a few hours instead of living through months of grinding frustration.

A number of readers have suggested that I start a new national organization and do the amateur radio promotion which needs to be done. No, I don't need the aggravation that fighting the League would bring. No, you're going to have to either clean up the ARRL or else take up a new hobby when we lose this one through neglect.

We need to do something to revive an interest in CW. Our bands are split into CW and voice subbands, but it doesn't take much listening before you discover that the voice bands are busy and the CW bands oddly vacant. I've gotten several letters recently from hams who've taken the time to count signals on a regular basis. This might be a good club activity. Assign different bands to your members and get them to make an hourly activity count of CW, RTTY, Packet, SSB, SSTV and AM signals on each HF band.

If you'll run the counts and send 'em in, I'll get 'em correlated so we'll have something approaching a scientific study. We need to know how much activity we have on what bands. . . when. In counting, never mind how many stations are in nets. We just want to know how many frequencies are being used for contacts. . . so a net or even a DX pile-up would count as one contact.

In sending In reports, please mention if you're part of a club activity (and the club). I'd like to publish a list of the clubs which have shown enough interest in the hobby to help with projects like this.

As far as I know nothing like this has been done by amateurs before. Some commercial studies of amateur band use have been done in preparation for pressuring the FCC to give them parts of our bands. They used wideband spectrum analyzers and video tape. . . which not many of us have access to.

The Pudding

Will this new no-code Tech license open the floodgates and get us into a growth mode again? I hate to be Ol' Doc Gloom, but I'll be surprised if this alone makes much difference. We'll know more a year from now when we can compare the change in new licenses being issued.

Notes from FN42

Several weeks ago after parking my car at work, I was pleasantly surprised when a car stopped, and a young man stepped out and asked me if I was a ham. He had seen my callsign on my license plates and wondered if I knew of any local clubs offering ham classes. I had to admit that I didn't, but that I'd check, and that he should call me at my office.

I haven't found a club yet with classes going on, but I've been thinking about trying to do something myself. In the non-ham world, I teach at a small liberal arts college in New Hampshire. What about a one-semester ham course, meeting about one evening a week? That'd be at least 14 meetings. My understanding from other faculty is that there used to be a ham station on campus for faculty and students. It appears that the ham shack and equipment have passed into oblivion. But ham radio has not! Anybody in the Rindge, New Hampshire, area want to help me?

This brings up a subject I discussed with David N1GPH, my fearless leader (after Wayne, of course). Wouldn't it make sense for 73 Amateur Radio Today *to sponsor ham classes at the elementary and high schools in the New Hampshire area? David said that it would, but only if people wouldn't think that 73 was doing it just to sell subscriptions and Wayne's code tapes and study material.*

I had to admit that I hadn't thought of it that way, but he was probably right. Then I asked my favorite question, WHY? WHY can't ham radio magazines and their employees sponsor ham classes? WHY can't we use some of the magazine's resources to increase the numbers in our wonderful hobby? Don't many of our clubs strongly suggest to our struggling Novices-to-be that they purchase one set of code tapes or the other, and one particular study guide or the other? WHY is that any different from 73 or QST or CQ suggesting that the student use certain study materials?

Since this column is supposed to zero in on international happenings, I will pose the same question to ALL hams. WHY can't ham magazines use their integral talents and resources to increase the ham population of the world? You tell us whether ham magazines should or shouldn't be able to sponsor ham classes.—Arnie N1BAC.

USSR

Early in 1989 a new radio club, "Advanced Communications DX Association (ACDXA)," was formed in the USSR to promote the usual good things that radio clubs try to do, such as foster international friendship and good will, and sponsor contests and expeditions. The founders are Valery RA9YD and Yuri UA9YE. Both are officers of the association.

ACDXA Awards Program. The ACDXA awards will be issued to any licensed amateur or listener over the world.

Each contact must be confirmed in the form of a QSL card received by the applicant.

Each application must be accompanied by a list showing the dates of the contacts, and include a statement by two licensed amateurs that the necessary cards have been checked.

Contacts must all be made from the same country, on any band or mode, beginning January 1, 1985, if a specified requirement is not indicated in the rules.

After receiving the basic award, only the necessary additional confirmations are required for a higher class or endorsement.

The certificates are available for a fee of 7 IRCs or 3 IRCs per endorsement.

The cost of a plaque or trophy is 50 IRCs. In all cases the fee includes surface mail return postage. SCA and ACDXA Supertrophies are free.

Applications must be sent to the awards manager, ACDXA, PO Box 1, Barnaul 656057, USSR.

ACDXA. The applicant has to prove QSOs with 5 ACDXA members.

The ACDXA plaque is available for any applicants who have [been able] to prove contacts with each current ACDXA member.

Only contacts made on or after January 1, 1990 are acceptable.

All Soviet Nationalities Award (ASNA). In the spirit of developing friendly relations among nations and nationalities, the award will be issued to encourage communications with different national areas within the Union of Soviet Socialist Republics.

See the table for the basic award and trophy rules.

Territories for ASNA: Soviet Socialist Republics: UA, UB, UC, UD, UF, UG, UH, UI, UJ, UL, UM, UO, UP, UO, UR.

Autonomous SSRs: UA1N, UA4P, UA4S, UA4U, UA4W, UA4Y, UA6I, UA6J, UA6P, UA6W, UA6X, UA9W, UA9X, UAØO, UAØQ, UAØY, UD..N, UF..Q, UF..V, UI..Z.

National districts: UA1P, UA8T, UA8V, UA9G, UA9J, UA9K, UAØB, UAØH, UAØK, UAØX.

Autonomous oblasts: ..UA6E, UA6Y, UA6Z, UAØD, UAØW, UD..K, UF..O, UJ..R.

Soviet Cities Award (SCA). The applicant has to prove contacts with 100 cities of the Soviet Union.

Special endorsements are available for each additional 100 cities.

SCA-trophy is available for the achievement of 500 cities.

SCA-Supertrophy is available for achievement of all cities worked on the date of the application signed. All QSLs and appropriate return postage are to be sent to the awards manager.

The list of the Soviet Union's cities is available from the awards manager. Please SASE or SAE and 5 IRCs.

Good Neighbor Award (GONA). The applicant has to prove contacts with all countries which border the USSR.

Special endorsements for any band or mode are available.

The GONA-plaque will be issued to an applicant who has [been able] to prove contacts with all countries as those for GONA-certificate on each of five HF bands.

One necessary contact on each band may be substituted for a contact with another country adjacent to the necessary country, if the contact has been made on RTTY, AMTOR, or packet.

The list of countries: AP, BY, EP, HA, JA, JT, LA, OH, OK, PS, SP, TA, VU2, W, YA, YO.

"Ninety-Degree Line." The applicant has to prove contacts with those foreign countries and Soviet oblasts which lie on the 90 degree meridian. A5, BY, HC8, JT, S2, TG, UAØA, UAØB, UAØH, UAØW, UAØY, VE, VU, W, XE, YS.

U-RTTY-Award. In an effort to encourage digital communications on radio amateur bands, the U-RTTY-Award will be issued to any amateur or listener who can prove contacts with all ITU-zones within USSR (19–26, 29–35).

ACDXA-Supertrophy. The ACDXA-Supertrophy may be claimed by any holder of the following: ACDXA-plaque, SCA-trophy, GONA-plaque, ASNA-trophy, and U-RTTY-Award.

	USSR	DX
Basic award	51 QSOs*	25 QSOs**
Trophy	51 QSOs – 5 Bands***	51 QSOs – 3 Bands****

* – 15 Soviet Socialist Republics
20 autonomous SSRs
10 national districts
8 autonomous oblasts
any band, any mode

** – 10 Soviet Socialist Republics
15 autonomous SSRs
any band, any mode

*** – 51 QSOs on each of 5 HF bands, any mode
**** – 51 QSOs on each of either three HF bands, any mode

[In the following, please note 9M6HF's comments on pile-ups and the purpose of amateur radio. You can enjoy contesting and still be considerate—and maybe even take a few moments to talk about your interests and activities!]

MALAYSIA

Harris Abdullah 9M6HF
P.O. Box 13329
88837 Kota Kinabalu
Sabah Malaysia

Local activities. MARTS has, for the third year running, provided communication facilities during the Rally of Malaysia from September 1–4. This event, organized by the Malaysian Motor Sports Club (MMSC), gives MARTS members the opportunity to improve their traffic handling abilities. MMSC also organizes the World Superbike Championship on November 1–4 in Shah Alam, with MARTS participating.

The SEANET Convention was a success, attracting amateurs from 18 countries. As I was not able to attend the convention, I am not able to write a detailed report. This event, sponsored by the state government, was very well-organized, thanks to Festus Havelock 9M8FH. Due to his effort, interest in amateur radio in Sarawak has been revived. More stations with the 9M8 prefix should be on the air soon.

In 9M6, licensed amateurs and SWLs did their part in community service by providing the total communication facilities for the Climbathon, an annual mountain race up and down Mount Kinabalu (4,100 meters), organized by the Sabah Tourism Promotion Corporation. Held September 1–2, this is the second year in which the Sabah Amateur Radio Society has provided the service. Control stations were set up at intervals along the route to the peak. The guys who had volunteered to be stationed at the peak had to trek up the mountain from the base. As the event was held over two days, these poor guys had to do that twice, except that the second day's trek was from the resthouse located at the 3,000-meter level.

DX Activities. In 9M2, a number of amateurs are active on the air. Among them are: 9M2ZA, Zainal; 9M2AX, Ross; 9M2DX, Faizal; 9M2DW, Tan; 9M2GW, George; and 9M2KN, Ken. These are the stations I know of who are on the air frequently, and who can be heard mostly in the evenings (0700 UTC onwards). Other stations are also active on the HF bands at other times.

From 9M8, regulars on the air are: 9M8GH, Festus and 9M8PV, Andy. 9M8FH sometimes checks in with the W7PHO Net on 14.226.5 MHz. 9M8ZR (WA2HZR, Dave) was active in November, operating the last week of that month from Western Malaysia with the call 9M8ZR/2.

Active stations from 9M6-land are 9M6MO, Mohammad; 9M6JR, Janin; 9M6ET, Steve; 9M6IO, Senny (YL); 9M6HS, Hussein; 9M6MA, Hassan; 9M6MU, Alfons; and myself. All these stations are active on most weekends. 9M6MO has regular weekend skeds on 21.160 at 0800 UTC with his QSL manager. 9M6ET meets his QSL manager on 21.220 at 2300 UTC, and 9M6HF has a regular sked on 21.350 at the same time during the weekends. Of course, contact depends on the propagation conditions.

Stations soon to be on the air are 9M6MX, Mann and 9M6AF, Ken.

I am able to work all modes and bands except satellites and 160m. The only satellite station belonged to 9M6KT, Mike, who went QRT when he returned to the states last November. Most of the stations mentioned above have modest setups and only dipoles. 9M6MO, 9M6MA, 9M6MU, and 9M6HF are the only stations with tribander yagis.

9M6NA, Sate (JE1JKL) and 9M6OO, Bob (N2OO) were active from the middle to the end of November 1990. 9M6QQ, Hans, was also on the air during the same period, operating from two islands, Labuan and Banggi, for the IOTA award.

Local Growth. The amateur radio community is growing, albeit at a very slow pace. MARTS reported recently that there are 309 licensed amateurs in Malaysia, which includes Sabah and Sarawak. SWLs, of course, outnumber these by a factor of at least 2 to 1. It's quite amazing at how easily a 9M prefix attracts a pile-up, especially when the bands are open. Working through a pile-up is a tiring job, and most of us here prefer a nice chat and getting to know the operator at the other end, instead of trying to break their QSO record. Isn't the main aim of amateur radio to strengthen international goodwill and friendship? So, how do you achieve this by exchanging callsigns and signal reports? If you have an answer, I would be glad to hear it.

The "Lookie-Talkie"

With the current trend towards miniature video components, it was inevitable that someone would come up with the video equivalent of an HT. Earl Campbell KS8J of Glendale, Arizona, has put together what he calls the "Lookie-Talkie." (See Photo A.) Take a small pocket portable TV set, a 1 watt ATV transmitter, a miniature B/W TV camera, preamp, gel cell and a 440 MHz rubber duck antenna, then mount it all in a plastic project box and you have an extremely portable ATV station. Now when Earl wants to go portable or mobile ATV he just grabs the "Lookie-Talkie" and heads for the door. . . no messy cables and adaptors to worry about!

Photo A. The "Lookie-Talkie."

Build your own "Lookie"

Use a Radio Shack Pocketvision 22 (the 23 and 24 models will work as well, but are somewhat larger) for the ATV receiver. This series of pocket LCD TVs tune directly through the 70cm ATV band and even tune below 421.25 MHz. With the addition of a Hamtronics preamp kit (LNW-400), you will have a very sensitive receive station.

Remove the back of the TV set to conserve room and mount it through a hole in the lid of a plastic project box

Photo B. The "Lookie" compared with a Yaesu 2 meter HT.

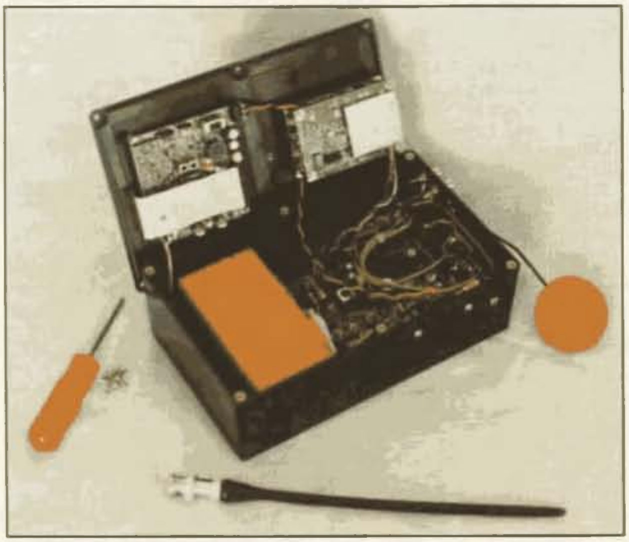

Photo C. Internal view of the "Lookie". Note that the TV camera and the back of TV receiver have their cases removed. Main part of the case contains the Kreepie-Peepie transmitter and the battery.

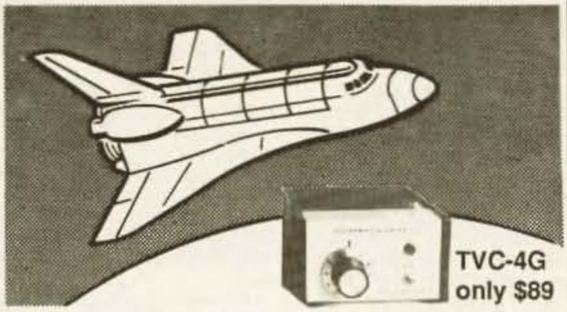
Photo D. KS8J ATV repeater site on top of Shaw Butte overlooking greater Phoenix. Roger KD7HH and Wayne N7MAO can be seen installing the new antennas.

Continued on page 78

AMATEUR TELEVISION



SEE THE SPACE SHUTTLE VIDEO

Many ATV repeaters and individuals are retransmitting Space Shuttle Video & Audio from their TVRO's tuned to Satcom F2-R transponder 13. If it is being done in your area on 70 CM, all you need is one of our TVC-4G ATV 420-450 MHz downconveters, add any TV set to ch 3 and 70 CM antenna. Others may be retransmitting weather radar during significant storms. Once you get bitten by the ATV bug - and you will after seeing your first picture - show your shack with the TX70-1A companion ATV transmitter for only $279. It enables you to send back video from your camcorder, VCR or TV camera. ATV repeaters are springing up all over - check page 411 in the 90-91 ARRL Repeater Directory. Call for a copy of our complete 70, 33 & 23 CM ATV catalog.

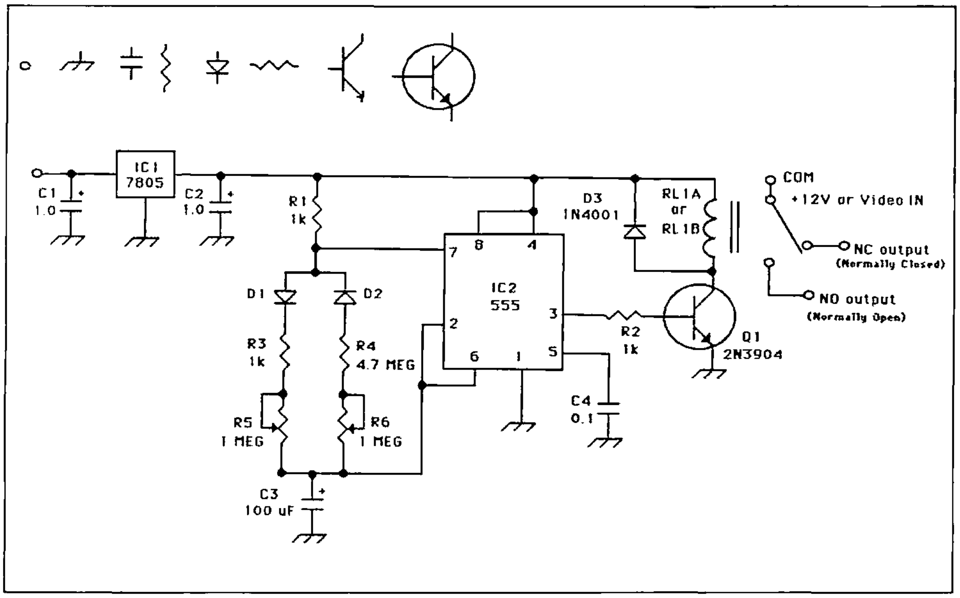

Figure 1. Ten minute timer schematic.

(RS# 270-224 or 270-232). (See Photo C.) Connect a Hamtronics preamp between the TV set's antenna jack and the DPDT antenna switch on the top of the box next to the BNC antenna jack. Just above the TV receiver, mount the small B/W TV camera with its case removed. This particular model was the Mitchell Industries Micro-Video camera. (The GBC CCD-100 is a similar sized camera and could be used as well.) Mount a P.C. Electronics KPA-5 transmitter to the back of the project box just above the 1.2 Ah gel cell battery.

The DPDT switch on the top of the box is used to switch the antenna jack from transmit to receive, as well as to supply power to turn the ATV transmitter on and off. Optional switches can be mounted for external audio or video inputs as well. Button it up and you should be ready for some real portable ATV action.

Walking around Phoenix with the "Lookie," Earl can watch the local ATV repeater with a P3 or better picture from over 20 miles away. He has taken it up on several flights on board a research jet for some really wild DX. His most recent flight took him from Arizona to Italy on a Cessna Citation jet at 42,000 feet. During this flight he used the "Lookie Talkie" to make aeronautical ATV contacts in Arizona, Minnesota and Great Britain!

Now that the video HT is a reality, who'll be the first with a Dick Tracy style ATV wristwatch?

Phoenix ATV

The AAA5 of Phoenix (Arizona Amateurs on A5) have quite an active group. Their local ATV repeater (KS8J/r) is about 2100 feet above the city on top of Shaw Butte. (See Photo D.) Shaw Butte is centrally located and provides coverage over a wide area of greater Phoenix. P5 quality reception has been consistently seen over 40 miles away. The repeater is vertically polarized with an input on 434 MHz (923.25 MHz alternate receive). Output is on 421.25 MHz. Most stations in the area need only 1 watt to access the repeater, so amplifiers are used only for distant simplex contacts or for mobile use. If you are in the Phoenix area, look for their weekly ATV net every Wednesday night at 7:30 p.m. The 2 meter talk frequency is via the 145.17 repeater (−600) or 145.17 MHz simplex. They can also be found on the 147.28 (+600) repeater during net nights as well. No need to wait for the net, however, since there is tons of activity most any night!

Ten Minute ID Timer

This little circuit (Figure 1) solves the problem of identifying your ATV system every 10 minutes. You can use it to automatically switch in another source of video via the onboard relay (computer or identifier), or use it to switch 12 volt power to another relay or device. There are spaces for two different kinds of relays on the board (only one relay is necessary). I prefer the Aromat relay since it draws less current. This circuit will drive both relays, however, if you'd like to control more than one device (see Figures 2 & 3). The 555 (use the standard 555, not the CMOS version) timer charge and discharge paths are independently controllable via the 1 MEG control pots. I usually set it up to ID for 5 seconds every 10 minutes. I've used this same circuit in my live camera balloon flights to kick in the video ID board for 30 seconds every two or three minutes (using a 22 or 33 µF capacitor for C3). It's been a reliable performer and fits in a small space. You should use a high quality tantalum or low leakage electrolytic for the timing capacitor. To set up the on/off ratio initially, use a capacitor that is 10 times less than your final value. That way you can make your adjustments without having to wait a full 10 minutes! Then just replace the small capacitor with the final value. If you can't achieve the desired delay interval with the adjustment pot R6, try varying the values of C3 and R4.

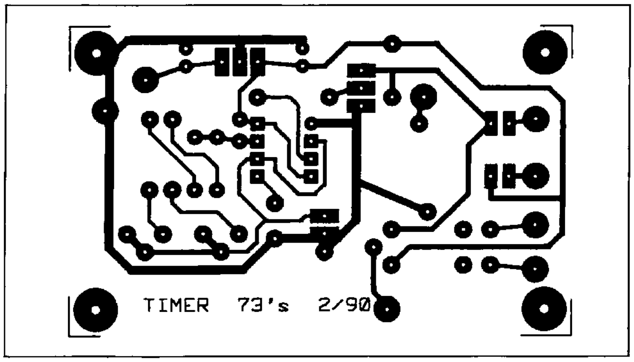

Figure 2. Timer PC foil pattern.

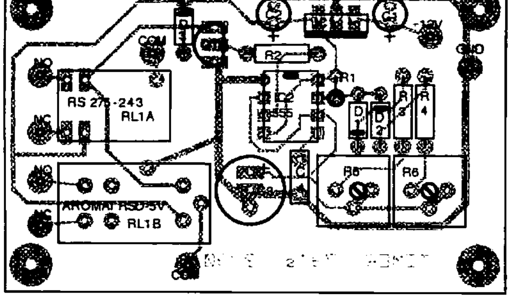

Figure 3. Timer parts placement.

Parts List (Ten Minute Timer)

R1,R2,R4	1k ohm ¼ watt resistor
R3	4.7 MEG ¼ watt resistor
R5,R6	1 MEG potentiometer
C1,C2	1.0 µF/35V tantalum capacitor
C3	100 microF/16V tantalum or electroytic capacitor
C4	0.1 microF disc ceramic capacitor
IC1	7805 5V regulator
IC2	555 timer IC
Q1	2N3904 NPN transistor
D1,D2	1N914 diode
D3	1N4001 diode
RL-1A	5 volt relay, RS#275-243
RL-2A	5 volt relay, Aromat RSD-5V (note 2)
Misc	8-pin IC socket, PC board (note 1)

Note 1: A blank PC board is available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for $4 + $1.50 shipping/handling per order.
Note 2: The Aromat RSD-5V relay is available for $2 + $1.50 shipping from ARE Surplus, 15272 S.R. 12 East, Findlay OH 45840. Phone: (419) 422-1558.

The Satellite Programs

Most universities do not build their own spacecraft. Until 1979 the University of Surrey in England was no exception. British university involvement prior to 1979 concentrated on the development of sensor systems, instrumentation, and detectors for experiments on board satellites built by industry.

Dr. Martin Sweeting G3YJO recognized an opportunity to expand the involvement of the University of Surrey to build small, low-cost spacecraft. Offered a launch opportunity by the United States, he and a small group of researchers in Surrey built not only satellite subsystems, but a whole satellite with its own power systems, experiments, control circuits and transmitters.

The goal was to create a satellite that could be monitored using simple systems on ham radio frequencies. The experiments were to be complex enough to stretch the abilities of university students, but still keep the emphasis on making the system output useful for educators at all grade levels, as well as for amateur radio operators. Experiments included a magnetometer, radiation counters, a charge-coupled device (CCD) camera, and an array of shortwave propagation beacons.

As Martin pointed out, today's school children are tomorrow's university students, and eventually our future spacecraft engineers.

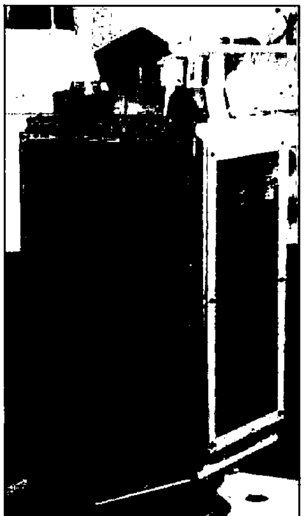

Photo A. This "fit-check" model of U-O-11 (launched 7 years ago) sits quietly in a lab at Surrey. (N5FVM photo)

UoSAT-1

UoSAT-1, also known as UoSAT-OSCAR-9, was launched by NASA on October 4, 1981, from the Vandenberg Air Force Base in California with the Solar Mesopheric Explorer. The launch vehicle was a Delta rocket. For the first days of its life, U-O-9 sent only an unmodulated carrier. Finally on October 9, 1981, the staff at Surrey managed to command U-O-9 to the 300 baud ASCII downlink mode. Until its fiery end in the atmosphere on October 13, 1989, U-O-9 sent telemetry either digitally via RTTY, CW or ASCII, or through the digital speech synthesizer system detailing the status of onboard sensors and experiments. The mission proved the viability of a university-inspired satellite program and generated interest from academic, technological, industrial and commercial sectors.

The success of the UoSAT-1 program encouraged G3YJO and others to continue with small satellites and to develop UoSAT-B, which would become UoSAT-2 or UoSAT-OSCAR-11 after launch. The U-O-11 mission was to fly a proof-of-concept digital store-and-forward communications experiment prior to a dedicated packet satellite spacecraft, and to use a launch opportunity made available by NASA.

The LANDSAT-4 Earth resources satellite needed to be replaced. The University of Surrey was officially informed of an opportunity in September 1983 for a ride to space in March 1984.

UoSAT-2

With only six months available, the team in England designed, fabricated, assembled, integrated and tested UoSAT-2, and were ready for another California launch from Vandenberg Air Force Base on March 1, 1984. Harold Price NK6K spent much of that time in Surrey living in Spartan conditions working with the Surrey team. The ride to orbit with LANDSAT-5 was uneventful, but only a day later the satellite would not respond to commands sent from the control station. After 10 weeks of intensive effort in England and at the Stanford Research Institute in California, U-O-11 was once again responding to commands and transmitting telemetry on 2 meters.

A logic gate had failed only hours after deployment, but the problem was not easily diagnosed from the ground.

U-O-11 is still in orbit and functioning. It is usually configured for 1200 baud telemetry on 145.825 MHz FM. The 350 mW 2 meter beacon can be heard successfully on most portable and mobile rigs. An old Bell 202-type modem with a simple modification to invert bit sense ("1" to "0" and "0" to "1") can provide the listener with plenty of telemetry to decode. Like U O-9, U-O-11 has a speech synthesizer, a CCD camera, and several modes for the telemetry downlink. U-O-11 also has a particle-wave experiment, a space-dust detector, and the Digital Communications Experiment (DCE).

UoSAT-3 and -4

On January 22, 1990, the University of Surrey added two more satellites to its continuing list of accomplishments.

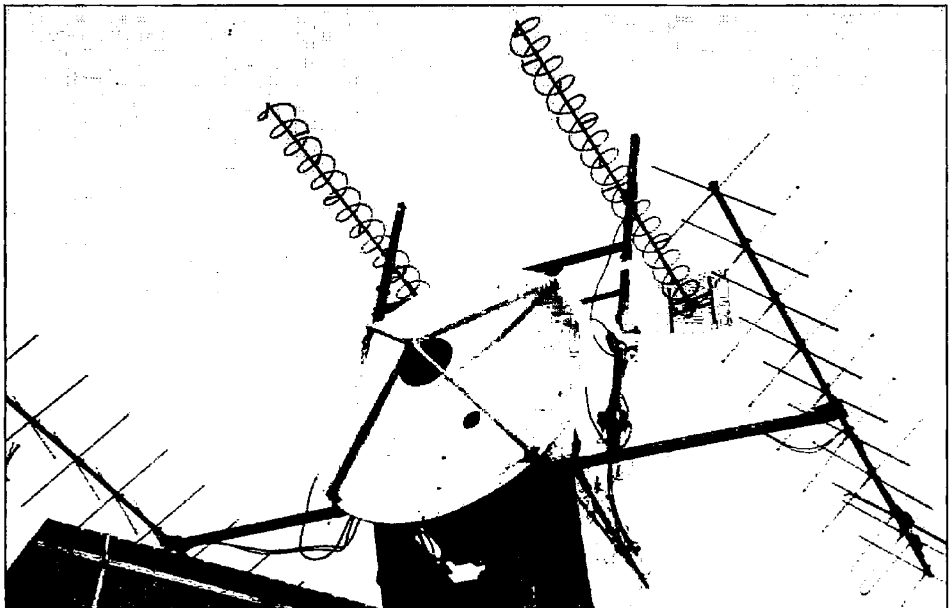

Photo C. Main University of Surrey satellite tracking antennas on a modified antiaircraft gun mount. (N5FVM photo)

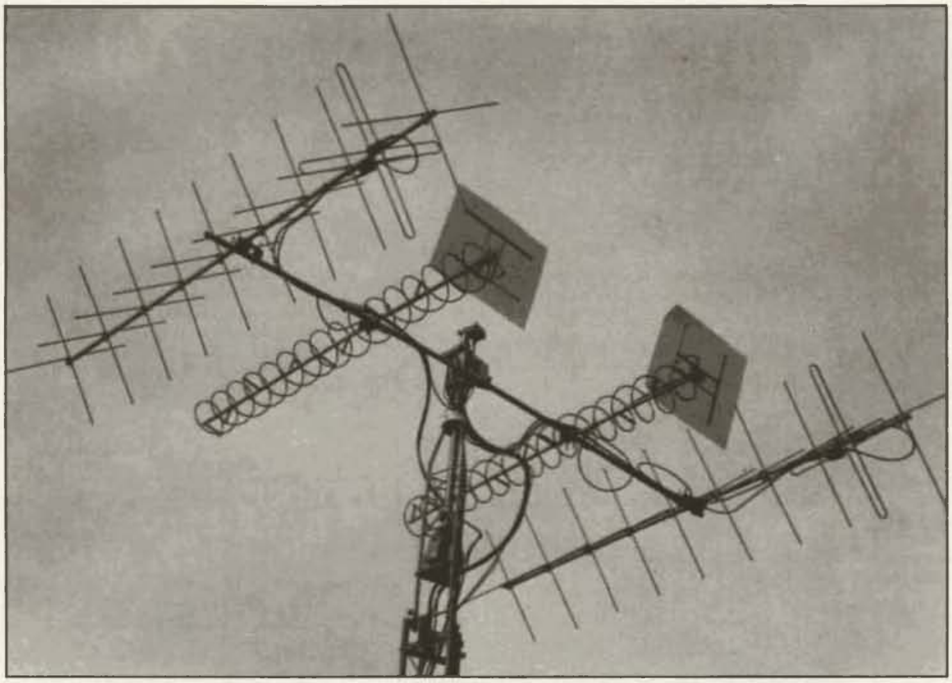

Photo D. Additional UoSAT antennas with crossed yagis on 2 meters and opposing helix antennas for 70cm. (N5FVM photo)

UoSAT-3, also known as UoSAT-OSCAR-14, and UoSAT-4 (UoSAT-OSCAR-15) were launched with the microsats by an Ariane-4 launcher as secondary payloads with the French SPOT-2 imaging satellite. UoSAT-OSCAR-14 is performing well with 9600 baud Mode "J" (2 meters up and 70cm down). The satellite also has cosmic particle and total radiation dose detection devices along with the packet radio communications experiment. Signals are loud and have been copied on incredibly simple systems. On several occasions, Jeff Ward GØ/K8KA has successfully connected to the satellite BBS and transferred several large files using portable radios and small antennas. For the 2 meter uplink he used a turnstile, while a small helix provided the downlink on 70cm.

Unfortunately, little has been heard from UoSAT-OSCAR-15 since the day after launch. Experiments on U-O-15 include a camera imaging device, transputer data processing units, and advanced European-made solar cells. Efforts continue to determine why it has not been transmitting, but the chances of recovery are dwindling.

UoSAT-F

Undaunted by the probable loss of U-O-15, the Surrey team is working on its replacement. After launch the new satellite will get an "OSCAR" number, but for now it is simply UoSAT-F. Many of the experiments of U-O-15 are being built again in the labs in England in preparation for launch this April on an Ariane rocket. Research Fellow Mark Allery G7DSY and others have been putting in long hours to finish the project. As if there weren't enough to do, the group must maintain operations on the current UoSATs.

The ground station at the University of Surrey was installed in 1975 to support control activities with AMSAT-OSCAR-6. It had only a few radios in a very small area so it did the job, but little else. By 1978 the system was expanded and was known as a "telecommand center" with several radios and an impressive automated antenna system using a modified Bofors antiaircraft gun mount. The antennas are still in use today, but other systems have been added. The custom tracking gear and connections to the university's mainframe computer have given way to 386 computers and arrays of displays for telemetry and tracking. Experimenters at Surrey continue to play a pioneering role in space education both in England and abroad, and at all education levels.

The ARSENE Satellite

Another satellite program developed for primarily educational purposes is the ARSENE satellite project from France (Ariane Radio amateur Satellite pour l'ENseignement de l'Espace). Many people have forgotten about this effort because of the delays and lack of information, but the project is still alive and may be launched in 1992 with the TELECOM-2B satellite as the main payload.

ARSENE was begun in the early 1980s and includes the Radio Amateur Club de l'Espace, Centre National d'Etudes Spatiales (CNES), 27 engineering schools, universities and colleges, and support from more than 40 companies. Student contributors number in the hundreds and the program has provided 87 engineering projects and one doctoral thesis.

The satellite is to be incorporated into the launch ring adapter between the main payload and the Ariane rocket. ARSENE is to act as a demonstration of how to accommodate secondary payloads with a minimum of mass increase and interface effort. It carries two transponders, one mode "B" (70cm up and 2 meters down) digital system, and an analog (voice, etc.) unit for mode "S" (70cm up and 13cm down).

The digital "B" system includes three distinct uplink frequencies and a single downlink using standard FSK modulation at 1200 baud. This configuration was chosen to allow standard packet-ready Earth stations access to ARSENE. The downlink transmitter runs 20 watts, so it should be easy to copy from modestly equipped stations.

The linear transponder with the 13cm downlink can be used with SSB, RTTY, CW or any other analog mode. Mode "S" on AMSAT OSCAR-13 transmits on 2401 MHz. ARSENE will come down around 2445 MHz. Current Mode "S" users will need to make appropriate modifications to make the 44 MHz move. Only one mode ("S" or "B") will be active at any given time. A schedule of operating times and modes will be determined by the STELA (Station de TELecommande Arsene) ground station. An onboard radiation dosimeter experiment is also included.

Physically, the satellite is nearly a cubic yard in volume, with a launch mass of 310 pounds. The orbit is to be elliptical with a perigee, or low point, of 12,430 miles; and an apogee, or high point, of 22,400 miles. This type of orbit yields a period of about 17.5 hours for one revolution around the Earth. The apogee boost rocket weighs 163 pounds and is made of carbon fiber materials. Spin stabilization will be around the "north/south" axis, and active attitude control (alignment relative to the Earth and sun) will be controlled by nitrogen gas jets. The power budget runs about 50 watts and the thermal control will be passive. Expected life is five years.

The ARSENE program has already contributed to the teaching of space technology. After launch it will continue that mission but will also provide the amateur community with a new space resource for communications experiments. 73

SPECIAL EVENTS

Ham Doings Around the World

Listings are free of charge aa space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

FEB

COATESVILLE, PA Reservation deadline for the Dayton Hamvention Bus Tour is 2/28/91. $143 cost includes motel for 3 nights, and bus fare. The bus will leave for Dayton Apr. 25th at about 7 AM and return Apr. 28th. Contact *TRIAC ARC, PO Box 304, Coatesville PA 19320. (215) 269-4844.*

FEB 2-3

MIAMI, FL The 31st Tropical Hamboree Amateur Radio/Computer Show and ARRL Southeastern Division Convention will be held at the Dade County Youth Fair & Exposition Fairgrounds. Admission $5 advance, $6 at the door. Swap tables: $20 each plus registration. Power, $10 per user. 3 day campsites $40 (Fri., Sat., Sun.). 4 day campsites $55 (Thurs., Fri., Sat., Sun.). Headquarters Hotel: Miami Airport Marriott—$65 single, double. Call *(305) 649-5000.* Speak only to Reservation Dept. and mention "Tropical Hamboree" to get special rate. For brochure and reservation forms: *Chairmen, Evelyn Gauzens W4WYR, 2780 N.W. 3rd St., Miami FL 33125. (305) 642-4139. FAX: (305) 642-1648.*

FEB 10

MANSFIELD, OH The Mansfield Mid-Winter Hamfest/Computer Show will be held at the Richland County Fairgrounds, beginning at 7 AM. Advance tickets $4, $5 at the door. Tables $9 in advance, $12 at the door, if available. Reservations must be received and paid by Feb. 1st. Talk-in: Call W8WE on 146.34/.94. For reservations send SASE to *Dean Wrasse KB8MG, 1094 Beal Rd., Mansfield OH 44905.* For info call *(419) 589-2415* after 4 PM EST.

FEB 16

MARLBORO, MA The Algonquin ARC will hold their Electronics Flea Market and VE Exams at the Marlboro Middle School Cafeteria from 10 AM-3 PM. Sellers set-up at 8 AM. Admission $2. Tables $10 in advance, $12 at the door. Wheelchair accessible. VE Exams start at 9 AM sharp. Pre-registration required. Send $4.95 check payable to *Mark Schneider WI1W, 14 Fuller Dr., Marlboro MA 01752. (508) 485-1857.*

RICKREALL, OR The Salem and Oregon Coast Emergency Repeater Associations will sponsor their 1991 Ham Fair at the Polk County Fairgrounds, beginning at 9 AM. Admission is $5 in advance, $6 at the door. Talk-in: 146.26/.86 repeater. Write to *1991 Salem Ham Fair, PO Box 784, Salem OR 97308,* or call *(503) 585-9554.*

FEB 16-17

SARASOTA, FL The Sarasota ARA wil sponsor its annual Hamfest/Computer Show at the Robarts Sports Arena. Free parking. Forums. Saturday's activities include a tour to Jungle Gardens. There will be a banquet at 7 PM. VE Exams Sunday at 10 AM. Talk-in: 146.910 repeater. Contact *Gene Marino, 4858 Tivoli Court, Sarasota FL 34235. (813) 355-0675.*

FEB 17

MELVILLE, NY The Long Island Mobile ARC will sponsor a Hamfest indoors at Electrician's Hall from 9 AM-4 PM. Admission is $5 at the gate. Exhibitors, $20 by reservation only. Talk-in: 146.25/.85. Contact *Neil Hartman WE2V, (516) 462-5549* or *Mark Nadel NK2T, (516) 796-2366.*

GOLDEN, CO The Aurora Repeater Assoc. will hold it's 10th Annual Swapfest at the Jefferson County Fairgrounds from 8:30 AM-2 PM. Contact *Judi WDØHNP, (303) 450-6910* or *Jan KA7TYU, (303) 680-8857,* or write: *Aurora Repeater Assoc., PO Box 39666, Denver CO 80239.*

FEB 23

ORANGE, TX The Orange ARC will sponsor its sixth Annual Hamfest-Flea Market at the V.F.W. from 8 AM-4 PM. Set-up at 7 AM. Tables $5 for individuals. $15 for dealers. Talk-in: 147.180+. Contact *Sherwood Buckalew KA5VOT, (409) 883-6111,* or *Dan Killough WB4GYS, (409) 769-9603.*

BURLINGTON, KS The Neosho Valley ARC will sponsor an Electronics Hobbyist Auction at the National Guard Armory beginning at 10AM. Set-up at 8 AM. Free admission. There will be a 10% consignment fee on all items purchased. Talk-in: 146.52 MHz. Contact *Bob, (316) 364-5448* or write to *V.A.R.C., Route 2, Box 38, Burlington KS 66839.*

BROOKSVILLE, FL The Hernando County ARA will hold its ninth annual Hamfest at the Hernando County Fairgrounds on US Hwy. 41 from 8 AM-3 PM. Free parking. Tailgaters' area available. Overnight parking permitted, but there are no facilities. Admission $3 in advance, $4 at the door. AMSAT seminar begins at 10:30 AM. Talk-in: 146.715/.115. Send check and SASE to: *Hamfest Chairman, PO Box 1721, Brooksville FL 34805.* For info call *(904) 796-4840 after 7 PM.*

FEB 23-24

CINCINNATI, OH The ARRL '91 Lakes Division Convention will be held at the Cincinnati Gardens Exhibition Center from 8:30 AM-5 PM Sat. and Sun. Advance tickets $6 (by 2/16/91), $8 at the door. Set-up from Noon-11 PM Fri. and 6 AM Sat. and Sun. Flea market tables, 8' x 4½' $15 plus general admission. Commercial "A" tables, 8' x 9', $50 each. Commercial "B" tables, 8' x 4½', $25. Contact *Stan Cohen WD8ODQ, (513) 531-1011* or *Joe Halpin W8JDU, (513) 851-1056.* Accommodations: *Quality Inn Central, Norwood OH, (513) 351-6000.*

FEB 24

DEARBORN, MI The Livonia ARC will hold its 21st annual LARC Swap 'n Shop Computer Fest at the Dearborn Civic Center from 8 AM-4 PM. Buy or sell amateur gear, computers or electronic test equipment. Free parking. ARRL/VEC Exams will be given by the Motor City Radio Club. Exam reservation deadline is 2/4/91. Call *Don Olzewski WA8IZV, (313) 294-4766* for exam appointments. Reserved table space 8' minimum. Talk-in: 145.35 repeater (-600) and 146.52 simplex. Send 4x9 SASE to *Nell Coffin WA8GWL, c/o Livonia ARC, PO Box 2111, Livonia MI 48151.*

CUYAHOGA FALLS, OH The Cuyahoga Falls ARC will sponsor their 37th annual Hamfest at the St. V. Center from 7 AM-3 PM. Wheel chair accessible. Advance tickets $3, $4 at the door. Tables $5 in advance, $6 at the door. Sellers may bring their own tables. Talk-in: 147.25 repeater (+600). Contact *Bill Sovinsky K8JSL, 2305 24th St., Cuyahoga Falls OH 44223, (216) 923-3830.*

ROCK ISLAND, IL The Davenport ARC will celebrate its 20th year by hosting its 1991 Hamfest at the QCCA Expo Center. Doors open at 8 AM. Wheel chair accessible. For VE Exam info: *Al Broendel N9OK, 2712 38th St., Rock Island IL 61201.* Advance tickets $3, $4 at the door. Tables are $7 each. Contact *Dave Johannsen WBØFBP, 2131 Myrtle St., Davenport IA 52804.* Talk-in on the WØBXR 146.28/.88 repeater.

MAR 3

NORTHAMPTON, MA The ML Tom Amateur Repeater Assn. Fleamarket will be held at Smith Vocational School, starting at 9 AM. Set-up at 8 AM. Admission $2, under 12 free. Tables $12 advance, $15 at the door. Contact *Marvin Yale N1CDR, 6 Laurel Terrace, Westfield MA 01085, (413) 562-1027.*

MAR 9-10

CHARLOTTE, NC The ARRL Roanoke Division will hold the Charlotte Hamfest/Computerfair at the Charlotte Merchandise Mart. For information write to *Charlotte Hamfest & Computerfair, PO Box 221136, Charlotte NC 28222-1136.* To preregister call *(704) 536-7373.* For Dealer booth info contact *Robert Starling N4GVF, 7021 Holly Hill Rd., Charlotte NC 28227. (704) 568-7611.*

MAR 15-17

ORLANDO, FL The Orlando ARC will sponsor the Orlando HamCation and ARRL State Convention at the new Fairgrounds in Orlando. RV parking. Handicap parking. Advance tickets $6 (deadline Feb. 21st), $8 at the door. Swap tables $25. Tailgating $10. FCC Exams. For reservations: *The Orlando ARC, PO Box 547811, Orlando FL 32854-7811. (407) 657-9052.*

SPECIAL EVENT STATIONS

FEB 1-10

VERNON, B.C., CANADA The North Okanagan RAC will operate Station VE7NOR during the 31st annual Vernon Winter Carnival. Frequencies: 28.575, 14.275, 7.175 and 3.775. The "Winter Carnival Award" is free, but please send $1 or 2 IRC's (to cover the cost of postage) and either a QSL card or log info of a QSO with VE7NOR, to *Winter Carnival Award-VE7NOR, Box 1706, Vernon, B.C. V1T 8C3, Canada.*

FEB 2-3

VT QSO PARTY The Central Vermont ARC (W1BD) will hold a QSO party from 0001Z Feb. 2-2400Z Feb. 3. Frequencies: (Phone) 80-15 meters, the first 25 kHz up from the beginning of the General phone band edge; Novice 10 meter SSB portion. 50.110, 144.2. (CW) 3540, 3720, 7040, 7120, 14040, 21040, 21140, 28040. (RTTY) 3620 & 90 kHz from lower edge of other bands. Exchange-VT stations send RS(T) and CW two-letter county designators: AN, BN, CA, CN, EX, FN, GI, LA, OG, OL, RU, WA, WM, WR. Other stations send RS(T) and state, province, or ARRL country. Scoring-VT stations: 1 point per phone contact; 2 points per CW or RTTY contact. Multiply by number of VT counties plus states/Canadian provinces/ARRL countries (non-W/VE). Add 20 bonus points to total score for working W1BD. Other stations: 1 point per phone contact; 2 points per CW or RTTY contact. Multiply by number of VT counties. Add 20 bonus points to total score for working W1BD. Rules-A station may be worked three times per band; once each on Phone, CW, or RTTY sub-bands. No duplicate or repeater contacts. W1BD may be worked on each different band for bonus points; (Phone, CW or RTTY). Awards-Non-VT: Certificate to highest-scoring station in each state, province, country (non-W/VE). Vermont: Certificate to each station submitting a log. Plaque to highest-scoring VT station. Special certificates for highest scoring stations in CW, RTTY, HF Packet, SSTV, etc. W/VT Award to stations working 13 of Vermont's 14 counties. Send SASE now for official score and log sheets. SASE for results. Send logs/facsimilies, name, address, county (Vermont), NLT Mar. 1st, '91 to *D. Loverin WA1PDN, 50 Liberty St., Montpelier VT 05602* Note: 146.52 will be used for working VT counties at 9 AM and 9 PM EST, during the contest.

FEB 3

ANAMOSA, IA The Jones County ARC will operate Station NØCWP from 1200-1800UTC in celebration of the First Anniversary of the opening of the Lawrence Community Center. Phone and CW operation will be on the lower portions of the General sub-bands on 15, 20 and 40 meters, and the Novice portion of 10 meters. For QSL, send SASE to *NØCWP, Jim McClintock, PO Box 462, Morley IA 52312.*

FEB 9

AUSTIN, TX Station N5OWD will operate from 1400Z-2300Z to commemorate the 10th anniversary of The Armadillo BBS. Operation is in the Novice/Tech phone portion of 10 meters. For certificate, send QSL and SASE to *Ron Hawkins N5OWD, 1459 South Meadows, Austin TX 78758.* The Armadillo BBS, (512) 837-2003, answers 300-2400 baud callers and operates 24 hours a day in support of amateur radio/TV operators and others. It also contains a library of HAM-related files.

FEB 9-10

PHOENIX, AZ The Motorola ARC of Arizona will operate Station KB7FZC from 1500Z Feb. 9-0200Z Feb. 10, in commemoration of Arizona Statehood Day. The station will be based at Papago Park, near the tomb of George W.P. Hunt, First Governor of Arizona. Frequencies: CW-7.130, 14.050, 28.050; SSB-7.150, 14.280, 18.155, 21.380, 28.450 MHz. For an unfolded certificate, send a large SASE with your QSL card to *John Tucker KB7FZC, 2802 N. 34th St., Phoenix AZ 85008.*

FEB 11-15

NEW YORK The Fifth Annual School Club Roundup (formerly Operation SEARCH), is sponsored by the Council for the Advancement of Amateur Radio in the New York City Schools, the ARRL and its Hudson Division Education Task Force, to foster contacts with and among school radio clubs. The Contest will operate all week from 0800—2000 EST. Operate no more than 24 of the 60 hours. Logs must clearly show on and off times. Off periods must be at least 30 minutes. Classes: (I) Individual or Single Operator (non-club); (C) Club or group (non-school); (S) School Club or group (grades K-12). Exchange-Call sign, RS(T), class, US state or DX country. Scoring-No repeater contacts except satellite and "real time" packet. Stations may be contacted once each on phone and CW (Packet and RTTY count as CW). One point for each phone QSO. Two points for each CW QSO. Multiplier-Number of states plus DX countries plus 2x "C" class QSO's plus 5x "S" class QSO's. Final Score-Multiply QSO points by multiplier. Reporting-Sample log and entry forms are available for an SASE. Mail entries to *School club Roundup, c/o Lew Malchick N2RQ, Brooklyn Technical HS, 29 Fort Greene Place, Brooklyn NY 11217.* Logs must include exchange info, bands, and signature of all operators (and authorized club official or trustee). Dupe check sheets required for entries over 100 QSO's. Postmark by 3/18/91. Awards-Certificates for top three entries in each class. Special certificate for any station contacting ten or more school clubs. Send a large SASE or sufficient IRC's for complete results and more info about CAAR/NYCS.

FEB 14-17

LOVELAND, CO The Loveland Repeater Assoc. will operate Station KAØVFF (Valentines for Friends) from 1500-0500 UTC Feb. 16th and 17th, with some activity on Feb. 14th and 15th from 2500-0500 UTC. Frequencies: 25 kHz up from the lower portion of the General class phone and CW bands. Please QSL via *KAØVFF, Michael H. Walker, 3816 Ash Ave., Loveland CO 80538.* Send a SASE for your 8½" x 11" certificate commemorating Valentines Day from Loveland.

FEB 16-17

APACHE JUNCTION, AZ The Superstition ARC will operate Station WB7TJD in commemoration of Lost Dutchman Days from 1400Z-0200Z. Frequencies: 20, 15, and Novice section of 10 meters. Local contacts via 147.12 MHz. For special certificate and club QSL card, send 2 units postage on 8½" x 11" SASE to *SARC-WB7TJD, PO Box 1551, Apache Junction AZ 85217.*

FEB 22-24

WAIMEA, KAUAI The Kauai ARC will operate Station KH6HU from 2000Z Feb. 22-0600Z Feb. 24 to commemorate the landing of Captain James Cook. Frequencies: 25 kHz up on the General 80, 40, 20, 15, and Novice 10 meter phone bands. For certificate, send QSL and SASE to *KH6HU c/o KARC, PO Box 548, Kalaheo Kauai, HI 96714.*

FEB 22-MAR 10

FAIRBANKS, AK Station KL7KC will operate during the running of the Eighth annual Yukon Quest International Sled Dog Race. Frequencies: General portion of 80, 40, 20 and 15 meter bands; Novice portion of the 10 meter band. CW operation will be on or near 7.050, 14.050, 21.50, 28.200. QSL via *KL7KC, PO Box 81389, Fairbanks AK 99708.*

FEB 23

YUMA, AZ The Yuma ARES will operate Station N6RTV at 1500-2400 UTC to commemorate Amateur Radio Day 1991 in benefit of the International Red Cross. Frequencies: 10 meter Novice SSB-28.418 MHz; 15 meter General SSB-21.318 MHz; 20 Meter General CW-14.034 MHz. A unique certificate confirming communication with the internationally recognized Official Center of the World is offered to all amateurs submitting a QSL confirmation and 9" x 12" SASE to *Yuma ARES, c/o U.S. Post Office, Felicity CA 92283.*

No Code

So. . .it's finally here. As we put the finishing touches on this issue, the FCC has announced the passing of a no-code license. Judging from what I've heard on the bands, most people are turning what is an elegantly simple solution to the no-code question into something much more complicated than it really is.

In a nutshell, here is the no-code license:

The no-code Technician license will retain all frequency privileges above 30 MHz (that's 6m, 2m, 220, 440, 1.2, etc).

The Technician test will consist of 55 questions.

Technicians will be given Novice HF privileges upon completion of a 5 wpm code test, administered by three volunteer examiners (the same way all upgrade tests are administered).

There is no change in any other license class. The Novice test and privileges stay the same, as do the General, Advanced and Extra. If a Technician wishes to obtain a General Class license, he would be required to take the 13 wpm code test, as well as the general written exam.

There will be no special call sign designation for no-code Technicians.

Current Technicians keep all HF privileges.

I must applaud the FCC for this simple solution to what has been an ongoing pain in the butt for them. It's a solution that makes an incredible amount of common sense. Coming from a government agency, I am stunned! Maybe we ought to let the FCC handle the deficit!

True to form, the ARRL is questioning the wisdom of letting these no-code Techs have 2 meter privileges. This smells of elitism on the part of the League (i.e., "Let's save 2 meters for us 'real' hams and put the no-code crowd up above 220 MHz, where we don't have to associate with them.") It also sounds like the League is a bit miffed over the fact that the FCC didn't adopt their idiotic and complicated proposal. Alas, the League's reaction is what we've come to expect from those old do-nothings in Newington.

Many hams are still bellyaching over this no-code license. Many still think that a code test keeps out the riffraff. People who use this argument must not spend too much time operating. Just listen to 75m phone some evening. How about the rude and discourteous operators on 10m, especially during contests? Let's not ignore the never-ending tirades of the looney tunes on 14.313. (At this point, don't you want everybody involved in that childish, egotistic baloney to just shut up?) A few of the 14.313 morons have made their way down to 40m, too. Since they all use callsigns, we may assume that they all have taken a code test. So much for the code keeping out the riffraff.

There's a whole other contingent (headed up by our buddies down in Newington) who don't mind having a no-code class of license—but put them up above 220 MHz (which translates into "keep 'em off of 2 meters"). With about two minutes of brain warming you can figure out how destructive this course would be. The only way to teach a new ham how to operate is to put him on the bands with other hams. If we put all no-code licensees up above 220 MHz, far away from the bulk of most amateur operating, it wouldn't be long until they became a separate group with their own way of doing things. This wouldn't necessarily be a bad thing, but it could degenerate into another CB-like situation. It is much better to put these new no-code licensees right on the most popular band—2 meters—and let them learn proper amateur operating practices (of course, this assumes that there are proper amateur operating practices on 2 meters for these new people to emulate).

Another complaint I've heard is that 2 meters is too crowded already. This new no-code license will just make it more crowded. Again, fire up those brain cells and you will soon realize how absurd this statement is. Sure, we have wall-to-wall repeaters on 2 meters. The entire North American continent is full of 2 meter repeaters. People who want to set up a repeater on 2 meters generally must wait for the owner of a current repeater to die before a frequency pair becomes available. The only problem is that most of these repeaters are silent. Nobody's using them!

Sure, every area has its most popular repeaters. Large population areas may have several well-used repeaters. Still, I defy you to prove that every repeater we currently have in operation in this country is being used. Even in major cities you can scan through dozens of repeaters and not hear a single voice for most of the day. We could quadruple the number of hams on 2 meters, and there'd still be room enough for everyone (unless you're a snob and don't want anyone but your little group of buddies to use your repeater).

Let's face it, folks. It's about time that amateur radio entered the '80s (I know it's 1991, but we must take it a step at a time). Morse code is a really fun way to communicate, but it is only one way, and not a very efficient way at that. What would you say if we required all licenses to be tested in SSTV. . .or RTTY. . .or packet. . .or EME moonbounce? They're all valid modes of communication. Why should we hang onto this antiquated mode of communications as an entry requirement? Most of us lose what little code proficiency we have 10 minutes after taking our test, so what's the point?

The question of no-code has been argued back and forth for over 10 years. We've all had our say. We've all heard just about every argument for and against. The FCC, after considering every viewpoint, has finally come up with a no-code license, and miracle of miracles—it makes sense! The time for arguing is now over.

Will a no-code license, by itself, be the salvation of amateur radio? No. Just about everyone who wants a ham ticket has been able to get one. Sure, we'll increase our numbers by a few percent, but will we see a surge of interest in this hobby? It's not likely. The problem has never been that people who want to be hams can't pass the code requirement. The problem is that most people have absolutely no idea what amateur radio is. It's a marketing and public relations problem.

Let's use this new license as a way to introduce amateur radio to the thousands of people we need to keep this hobby viable. Once we get 'em on 2 meters, let's get 'em hooked on HF so that they'll be motivated to learn the code and upgrade. The FCC has provided us with a great marketing tool. It's up to us to use it to our advantage. 73

An Unpredictable Cycle

Old Sol fooled us again! For the past several months, we have been commenting about how the sun had apparently reached a plateau, and might even be headed down again. . . when surprise, surprise! During August 1990, the highest observed mean sunspot number of 200 for this cycle was noted, and the solar flux index reached a fantastic 295, marking an all-time high for Cycle 22.

At the time of this writing, in November, no one can predict for sure what the sun will do next. It may start down, go up, or stay constant. Whatever your favorite view, it's easy to say that Cycle 22 has been the most unusual cycle observed for at least a century.

Now: February's dismal prognostication. There will be some good days, around the 10th and the 23rd, when the HF bands will be jumping with signals for a few days. Otherwise, conditions will be "Fair" trending toward good or poor, as the chart shows.

Your best bet will be to consult WWV for the daily forecast at 18 minutes past each hour to get a better idea of solar flux and magnetic field conditions. You can expect "Good" conditions when the magnetic field "A" index is 10 or below, and the solar flux index is 175 or higher. Trends toward *lower* "A" numbers and *higher* solar flux numbers mean a trend to good DX.

February, as a pre-spring month leading to usually peak-DX conditions in March, will be a good one to watch. March should be the best DX month for all of 1991, and February might well turn out better than predicted. Let's hope so. . . . 73

LETTERS

From the Hamshack

Pat DA2AA, APO NY Besides the issues in the early 70s when you were harping on the IRS, the Nov. 90 issue was among the best I have ever read! Keep 'em coming. I still remember our eyeball QSO here in Wiesbaden in May 1980. I was the guy sitting in the front row smoking cigarettes and drinking beer. . . .

And you're still alive? . . Wayne

Ben Bennett N7IVM, Bellevue WA I have just read "Never Say Die" in the December copy of *73*. As usual, when I read your column, I proceed cautiously, as I am never sure when something is going to leap out at me.

This time, however, I was unable to find any comments that I could disagree with. As usual, it seems as if the ARRL likes to start from behind the eight ball. The RSGB, of which I am also a member, has been working on this conference for at least three years, and they had no appeals for funds to help their effort. The inertia at the ARRL HQ is enormous, and I wonder whether you or I will live long enough to see much change. However, I am sure that that will not deter you.

Name withheld I've started writing some TV public service announcement spots that will target kids. As soon as they are finished, I'll pass them along for your input, and hopefully your support. I'd like these PSAs to be part of a larger campaign, with the spots serving to pique interest. Thanks for your encouragement. By the way, I spoke with some locals about this project and they thought that the ARRL should be the only ones to promote ham radio, that my ideas probably should be turned over to ARRL HQ, and that even if the spots were made, I'd never get them aired without ARRL endorsement (sigh). "Well," I replied, "if the ARRL wants to endorse them, great. If not. Who cares?" Wayne, I think you turned me into an unreasonable man.

How does the League manage to foster such complete idiocy? Your "locals" are certifiable nitwits. . . Wayne

Clifton Crews WD4MEI, Trussville AL Last night a neighbor of mine was in the shack. He is a CBer and a "sidebander." He is fascinated with packet and ATV, and is impressed with most of what he hears on 2m, but after listening to a little 75m phone, he said, "Man, on the lower side of 38 we wouldn't tolerate that kind of crap!" I almost split a side laughing.

I have listened in on some of his work on channel 38, LSB. It sounds like we all wish HF phone would sound. Well-behaved but slightly irreverent, interesting and well-done. This guy will make a fantastic ham without code . . . you see, he can't learn code. He's dyslexic, and code is just not in his brain's portfolio. All these years, he has been given the impression that he is not "good enough" to be a ham because of his inability to use code. I look forward to elmering him into a codeless Tech ticket, and working some ATV with him. He will be a better ham than most of the crotchety old guys crying doom and gloom.

Thaddeus A. Danley NZ3I, Eden Prarie MN I completely support the new code-free Technician license. Hopefully we will all work to welcome these new hams into the hobby.

Brett Breitwieser, Santa Cruz CA To celebrate the advent of the new no-code Tech license, I'm taking out a subscription to *73*. Thanks for the good work! I've been reading your mag for years. I'm 42 and a student of communications electronics at C.I.E., preparing for my radiotelephone op license. Now I'll get a new no-code Tech amateur's as well. Hope you will support the reality as you've supported the concept in the past.

This license is perfect for me since it's VHF/UHF I'm really interested in anyway, especially microwave. Let's get a bunch of new Techs and fill up those high bands before WARC! Would appreciate articles on proper procedures for new Techs and lots more VHF/UHF/microwave!

I see lots of signs of the usual stonewalling by the ARRL types on the computer nets and in the clubs. The new license is not for "real hams," it's a "boxtop license," etc. As though CW means anything anymore! Really laughable.

Let's make the new Tech license a real mark of distinction, real operator/builder/technicians opening up the microwave bands for the amateur community. Let's use the new license to juice up the amateur bands and help America regain its technological excellence.

Tuning the BBS: Ham #2 checks in on 2m after visiting ham #1 in intensive care. Ham #3 on the repeater asks, "How is he?" "Not too well. You should see all the tubes in him!" #2 says, "Gosh! All tubes. I didn't realize he was that old!" This brings a BBS response: That was shocking! Re-volting! Watt?!? At least that joke was current! *[They seem to use a lot of "Is" on BBSs.]* Another BBSer chimes in: We all take ohm-age to that joke. Do planar transistors sing "Ohm on the Range?" Where does the light go when it goes out?

Hmmm, bad as packet. . . . Wayne

A bad response to no-code from N0 Of course it was to be expected. Did anyone really think for a minute that the VHF bands wouldn't turn into a gigantic mess? And now that the feds have given 2m to the dogs, I hope that all of the no-code supports are feeling a bit like Judas. So much for saving 220 and 440, huh? Now all we need are repeaters set up exclusively for swapping recipes! Oh, well, there's always 10m FM.

To which a YL ham replies Excuse me? Going to the dogs? Swapping recipes? That's a sexist comment if I ever heard one. I'll have you know the examiner at my 13 wpm session said my copy was among the best he'd ever seen. I don't see how passing code is particularly more difficult than passing a 45-question written exam on theory. Depends on the person. If you listen to 14,313, those folks have all passed their code—many at 20 wpm! The problem with no-code isn't going to be people with a genuine interest in radio who did not like CW. The drawback will be people with an attitude problem who think that if they've passed a code exam that somehow makes them better operators than someone who hasn't. I hope you'll reconsider this CW bigotry.

Jonathan D. Armendariz, FPO San Francisco CA This letter is in response to your editorial in the Dec. '90 issue. It makes me glad that somebody has the same feelings I do. As an SWL, I passively listen to all the chaos going on, and it gets rather wild in my hometown (Los Angeles). I am not whining and crying, but as a prospective ham, is this what I have to look forward to? I want to be a ham because I love to communicate and make friends and hear from people of diverse cultures. However, if what I watch and listen continues, pretty soon there won't be much of anything left. Maybe the best we can do is to get together and try harder to think of some creative ways to get people interested, such as high school or college classes, new radio clubs, or maybe even a (GASP!) modified no-code license, something to get the young interested. Having the hobby dominated by old, closed-minded men shut to newcomers with new ideas, will cause its demise. All in all, wait till the ITU conference in 1992 and you'll see the shock on people's faces. After all, we are only hurting ourselves. I do appreciate the way you stand on your convictions, not being just another yes-man of the ARRL. I look forward to getting my ham ticket, but I'm concerned for what's ahead. *[This letter was written and answered before the FCC announced the new codeless license.—Eds.]*

If you'll notice—give it some thought—the worst mess on the air is coming from the least intelligent hams—chaps you don't want to waste a lot of time with anyway. Never mind 'em. Look for the hams with at least double-digit IQs and you'll do fine. . . . Wayne

Keith Baker KB1SF Soon after the FCC announced the long-awaited "codeless license," the following comments were heard on some local repeaters in the Dayton area: "Hate to see the code part go down the drain, we'll get all sorts of trash on the air now . . . Yes, maybe even them CBers . . . I suppose the bands will really be overcrowded now . . . Well, we can always go to 10 meters . . . They should give us regulars some new calls so we can tell us apart from them . . . There you go, they won't know beans about radio. . . ."

Count the number of "them's" and "they's" versus the "we's" and "us'es." These "concerns" about amateur radio have been around for years. I'm now firmly convinced we amateurs are afflicted with an almost universal phobia that ANYONE who enters the hobby AFTER ourselves is out to royally screw it up for those of US already here. I find it fascinating that WE weren't too concerned about these horrors when WE were trying to get our first tickets.

Face it: The real challenge facing amateur radio today is US! We talk about helping amateur radio grow. However, in our hearts, I believe many of us are doing our level best to erect barriers to keep THEM out. Have we ever stopped to think that THEM was US at one time? . . . Rather than erecting barriers for THEM, I suggest WE start making all our "growth" talk match our actions. How about becoming an elmer to one of THEM? When was the last time WE stopped by a Novice band to help a Novice or Tech with their code? When was the last time WE helped a newcomer put up their first antenna, or helped one of THEM set up their first shack, or answered THEIR questions about courteous operating practices? Who helped US get started in our hobby? Isn't it time WE returned the favor?

I suggest WE quit complaining, get off our collective finals, and start setting the example for our newcomers . . . before our new folks mistakenly assume the trash on 20 is the way it's supposed to be done! Inaction now may well seal the fate of our wonderful hobby. If we lose it, we'll only have US to blame!

Rick LaBrecque, Dixfield ME I recently passed my Novice and am diligently working toward Tech and General. I have an above average working knowledge of electronics, and feel each how-to article you print is great. Someone out there will say, "Boy, just what I was looking for," while the next guy will say, "Boy, I'd have to be a genius to build this gadget." We certainly can't please everyone.

What I would like to see is a Novice-Tech column EACH MONTH, with basics, such as learning code, building code oscillators, antennas, equipping the ham shack, proper grounding procedures. . . . I firmly believe that the Novice-Tech column is important, as is a General-Extra. . . . Not just a picture in the magazine showing kids or whoever just got their Novice ticket. Please talk this over, give it some thought, and keep it fresh in your mind, and keep it simple.

Rick, stay tuned. Wayne's got us working on a project that may be just what you're looking for. . . . David N1GPH

David N4YHC/AE, London KY Hello, I just thought I would send a quick note to tell you that I really enjoy your magazine. I have been getting it at the local bookstore.

Also, I wanted to say that I just passed Extra last night, exactly 364 days after I took my Novice test. I am 17 years old and a senior at my high school. I am one of three hams there. The other two are Techs.

I just wanted to tell you that the three of us are doing what we can to drum up some support for ham radio. Next week, we will be showing some video tapes and giving a brief talk in our physics class at my school. It seems that when everyone hears "radio," they think of channel 19 and that thing in their dashboard that puts out 100 dB. Anyway, we are doing what we can in our school paper to generate some interest.

David, I sure would like to see copies of what you're doing in your school paper. . . . David N1GPH

NEVER SAY DIE

Wayne Green W2NSD/1

Avoiding Cancer

The recent American Cancer Society report on the connection between animal fat and colon cancer was almost enough to get some Big Mac customers' attention. ACS president Dodd said, "Studies indicate that as many as 80% of all cancers may be related to the environment and things we eat, drink and smoke."

I suspect the good doctor is being conservative. Within a few years, if he doesn't smoke, I expect him to upgrade that to near 100%. I know I'm eating plenty of fiber, very little red meat, avoiding smokers, smog and magnetic fields. Of course I could still get shot by the Mafia for screwing up their investments in the music and magazine distribution businesses, but that's a health hazard I accept as a trade-off.

Sure, I like rare beef. Love it. But not enough to sacrifice several years of my life for the pleasure. I truly feel sorry for nicotine addicts who know they are devastating the last few years of their lives, but still are unable to stop smoking. They know it means cancer, heart trouble, emphysema, endless oxygen tank rentals and a nursing home, but even so the addiction is too overwhelming for them to stop.

The impact of magnetic fields, which is finally getting some media coverage, is almost enough to get you to re-read my old killer blanket editorials. Some blanket manufacturers are paralleling their heating wires to cut down the 60 Hz radiation, but that doesn't reduce the destructive thermostat switching transients. Have you bought comforters and wool blankets yet? Moved your linear away from the operating position yet?

It's still macho for college students to drink beer. . .the more they can drink, the more the macho. Other than death by highway, I don't know any way to discourage that age-old rite. Kids live and die for macho, just like men. When we can convince kids it's stupid to smoke and stupid to drink, we'll be progressing. Kids hate being stupid. It isn't cool. But how can we get the message across when dad, their prime role model, smokes two packs a day and tosses down a six-pack while watching ball games on TV every night?

Food is my addiction, so I know what it feels like to crave a fix. It calls for every shred of moral fiber I can muster to keep from overeating. Show me a delicious, luscious homemade apple pie and I'll show you a truly desperate man. Quitting smoking can't be much more difficult than breaking the eating habit. Oh, the torments! It isn't hunger. It's like the kitchen has this enormous magnet. Every time my guard is down it exerts this black-hole-like attraction.

It was 19 years ago I decided to hell with being fat. No pills, no canned diets. . .just a 1500 calorie a day diet and I took off 85 pounds at about ten pounds a month. I'd seen too many people drop dead from losing weight too fast, so I took it slow and easy. And I've kept it off pretty well. It can be done, even by a foodaholic like me.

Now stop grumbling about me trying to reform you. Sure, I know that most of you will get mad at me for butting into your life. But if even 1% have the guts to change, I'm willing to live with the hate. All I want you to do is live longer, healthier and happier. I want you to make enough money so it isn't a problem. And I want to do everything I can to keep amateur radio going so we can all both enjoy it and use it to help our country regain its industrial and financial strength.

Now, for you fatties. . .oh, I see you waddling around the Hamvention with your big fat guts hanging out over your belt. Here's how I lose weight. Breakfast I have a glass of fresh squeezed orange juice, a bowl of All-Bran with a banana and whole milk. Lunch is a bowl of oat bran with a half slice of English muffin toasted and a half grapefruit. Dinner I have a boiled quarter of cabbage (with a little butter), a chicken thigh and some spinach (or broccoli, kale, collard greens, turnip greens). I cook the thighs (all fat removed) with lots of onions in white wine (add some red pepper for heat). . .mmmm. . .or broil 'em with curry powder on 'em. A little cranberry sauce spices it up.

Yes, I know, you thought you bought a ham magazine, not a health book. You'd prefer a nice big fried ham slice with candied (a little brown sugar) yams and a fried pineapple slice, right? Okay, but just on Friday night, then it's back to your diet. And don't gorge.

No snacks. No potato chips, Doritos or cheese balls. No beer. No Coca-Cola. You're drinking water now, and lots of it. Flush out that stuff which has been clogging your system for years. If you have to add something to the water, make it ice. Oh, okay, tea or coffee (decaffinated) is okay. Actually, green tea is supposed to be fantastic for you. I've got to get some.

You won't get hungry with that kind of diet. . .other than a psychic hunger. That's when you find out whether you or your own personal devil is stronger. It's "a" devil, not The Devil. He's busy down in Newington dancing with

EDITED BY LINDA RENEAU KA1UKM

Bill to Protect Amateur Radio

On January 3, Rep. Jim Cooper (D-TN) introduced H.R. 73, a bill to prevent the loss of radio spectrum by the Amateur Radio Service. Cooper is a member of the House Subcommittee on Telecommunications and Finance, where the bill is likely to be sent for consideration. H.R. 73 is also known as the Amateur Radio Spectrum Protection Act of 1991.

The legislation proposes that "the Federal Communications Commission shall not diminish existing allocations of spectrum to the Amateur Radio Service after January 1, 1991. The FCC shall provide equivalent replacement spectrum to the Amateur Radio Service for any frequency reallocation after January 1, 1991."

ARRL President Larry Price W4RA welcomed Rep. Cooper's support of the Amateur Radio Service and expressed the hope that many congressmen will join him as co-sponsors.

Says Cooper: "I've come to believe that amateur radio operators are a valuable national resource, and I hope to see that they keep the necessary radio spectrum to enable them to be around for many years to come."

Congress found that (1) there are more than 490,502 licensed amateurs in the U.S.; (2) the amateur operates with a solely personal, nonpecuniary interest; (3) one of the basic purposes of the amateur is to assist in emergency communications; (4) amateur radio operators have reliably provided emergency communications; and (5) the FCC has taken actions (see the next news item) which resulted in the loss of over 100 MHz of spectrum to amateurs. *TNX ARRL via MCImail; HAMNET; and* W5YI Report.

220–222 Battle Lost

The fight to keep the lower two megahertz of the 1.25 meter band from reallocation appears to be over, and ham radio has lost. On December 5, 1990, the U.S. Court of Appeals for the District of Columbia Circuit denied the ARRL petition for review of the FCC order reallocating 220–222 MHz to the Land Mobile Service. In rendering its decision, the Court concluded that by law it had to give great deference to the views of the Commission. It also stated that it could not say that the Commission did not arrive at a reasoned decision about the best way to advance the public interest, convenience, or necessity.

The ARRL and the amateur community have no other legal recourse open to them other than clear legislation by Congress. Editor Art Reis K9XI of *220 Notes* spoke with ARRL General Counsel Chris Imlay N3AKD, and learned that the appeals court was the last stop in the legal process. The FCC is now in the position to set a date when hams must vacate 220—222 MHz.

Meanwhile, UPS is going to have to share the "new" 220-222 MHz "land mobile" band with the military. The Army requested and was granted an experimental license permitting its use of the entire 1.25 meter band. The Army plans to conduct basic research in buried mine detection in the Arizona desert using 2.918 megawatt ERP transmitters and sensitive receivers mounted in helicopters. Loral Corporation has developed the new system and will be overseeing the tests under the callsign KA2XAV, which expires on May 1, 1992. The signal bandwidth will be 10 MHz with a 100 nanosecond pulsed CW duration.

Before the 1979 WARC, the military informed the FCC that it would not require access to the 1.25 meter band after January 1990. Recent developments in the Middle East may in part be responsible for the military's decision to retain access. The type of research, and the geographical conditions under which it is being performed, make this appear very likely. *TNX* Westlink Report, *Numbers 591, 592.*

U2MIB On the Air

Soviet Cosmonaut Musa Manarov U2MIR, one of the first operators who brought amateur radio to space two years ago, is back on the air from *Mir*. During his last tour of duty, lasting 366 days, he spent much of his free time operating primarily on 145.55 MHz simplex FM.

A new packet radio setup is now operational on *Mir*. You can connect to Musa's BBS by the command *C U2MIR-1* when he is not operating live packet on 145.55 MHz. Also included is a voice synthesizer to transmit bulletins in Russian, German, and English. The *Mir* station uses a higher power multi-mode amateur transceiver than the one in SAREX operations, and the antenna is mounted outside of the space vehicle. These two items, plus *Mir's* 51 degree orbital inclination, make U2MIR's station accessible to most hams worldwide. *TNX* Westlink Report, *Number 592, and N6BVU.*

WAC with 50 mW

After building the FIRE-BALL transmitter from the November '90 issue, Mike Mayer W5ZPA of New Orleans set out to work as many countries as he could on 10m. Using just 50 mW on 28.060 MHz, Mike worked all continents in under 10 days! He now has a total of 16 countries and 20 states. Included in his list was a contact with the ZS9Z DXpedition at Walvis Bay, proving that you don't need multikilowatts to work those rare ones! *TNX K7IRK and WA6YPE.*

Half a Billion Miles...

On September 27, 1990, a new record for low power communications was set. Bill Brown WB8ELK, operating from the W2NSD/1 ham shack at *73* headquarters, successfully copied a 2.89 µW CW message on 28.638 MHz transmitted by Bob Moody K7IRK in Palestine, Texas. Bob was using a keyed HP-608D signal generator hooked up to a 3-element beam. Based on a distance of 1502 miles, this works out to over 519 million miles per watt.

Young Speakers Wanted

Carole Perry needs good speakers and presenters under 18 years of age for the Dayton Hamvention this April. She will be presenting "Youth in Ham Radio." She also urges every ham to bring a nonham child or young person to the Hamvention. Carole's address is at the top of her column, "Hams with Class," in this issue.

Satellite News

AMSAT-OSCAR-10 is supporting Mode B transponder operations. Apparently it is receiving sufficient solar panel illumination. The transponder may be used *carefully* at all points of the orbit except MA 254-006 when eclipses occur. If beacon or transponder signals show signs of FMing, users should cease all transponder use immediately.

Both of Fuji-OSCAR-20's transponders, JA and JD, have been turned on by the command stations. It was determined that transponder operation has little effect on the internal battery temperature.

Since mid-August, FO-20 has been in a non-eclipsing orbit, which means it has been constantly in sunlight. The battery temperature has risen to about 40°C. For normal operation, the battery temperature should be between 0 and 5 degrees. The command team for FO-20 will be monitoring the telemetry, and if they judge it necessary for the satellite's well-being, they may, without warning, turn off the transponders. *TNX* Westlink Report, *Number 591.*

QRX . . .

The SAREX STS-37 Mission

The STS-37 *Atlantis* mission, currently planned for early April 1991, will launch the Gamma Ray Observatory (GRO), the second of NASA's great observatories (the first was Hubble). Pilot Ken Cameron, a ham before becoming a NASA astronaut in 1984, is extremely enthusiastic about flying a SAREX experiment aboard his flight. He encouraged his fellow crew members to become hams, and all five astronauts now have their tickets.

The crew for the mission will be Commander Steve Nagel, pilot Ken Cameron, and mission specialists Jerry Ross, Jay Apt, and Linda Godwin. During the five-day mission that the crew will deploy GRO, Jay Apt and Jerry Ross will perform an EVA (ExtraVehicular Activity, or spacewalk) to evaluate Crew Equipment Translation Aids (CETA). These experimental space station "scooters" were designed to transport the astronauts from one portion of the structure to another, and to perform some mid-deck experiments, including SAREX. The SAREX STS-37 setup will use the same hardware and frequencies as the STS-35 setup, with the addition of amateur television.

On STS-37, live fast scan television (FSTV) will be uplinked from the ground on 70 cm. SSTV transmissions and reception to and from the shuttle will also be performed. NASA has been checking out a variety of portable home cameras for use aboard the shuttle. An 8mm Sony VCR/video camera will record the results from the mission's experiments. A Panasonic VCR/monitor, model PV-M429, will be used for slow and fast scan reception aboard the shuttle. The home model has been painted and wrapped in copper foil to reduce inflammability and EMI.

Since the Mir contact wasn't successful on the STS-35 mission, it will be a fairly important priority for STS-37. The crew's schedule may even be rearranged to make it possible.

Pilot Ken Cameron KB5AWP became an astronaut in 1984. STS-37 is his first shuttle mission. A Lieutenant Colonel in the Marines, he's clocked over 3,000 flying hours in 46 different types of aircraft. Since coming to NASA, he has worked on a Tether Satellite which will be launched next year. He's also worked on flight software testing, launch support at the Kennedy Space Center, and, appropriate for a ham, as CAPCOM (Capsule Communicator) for the STS-28 -29, -30, -33, and -34 missions. Besides ham radio, he enjoys flying, athletics, hunting, fishing, woodworking, and reading.

Commander Steve Nagel N5RAW first flew as a mission specialist on the STS-51-G mission in July 1985. Three satellites and a free-flying platform were launched. He was also a pilot on the German Spacelab D-1 mission, 61-A, In October 1985. Challenger's last mission, it carried a record eight people into space. When he flies as the commander of STS-37, he will become the first person to have flown aboard the shuttle in all three positions.

The all-ham crew of STS-37: Seated (l to r) are Ken Cameron KB5AWP, Steve Nagel N5RAW and Linda Godwin N5RAX. Standing (l to r) are Jay Apt N5QWL and Jerry Ross KB5OHL.

Mission Specialist Jerry Ross (who will be getting a new callsign) flew on *Atlantis*'s second mission, 61-B, in November 1985. The crew deployed three communications satellites and performed in-orbit drug manufacturing experiments. But the highlight of the flight was a spacewalk by Jerry and astronaut Woody Spring. They built two large, experimental tinkertoy-like structures for evaluating crew assembly procedures which may be used to build NASA's permanent space station in the future. Jerry's second mission was the *Atlantis* STS-27 secret defense department mission in December 1988 that deployed a radar spy satellite. By coincidence, Jerry closed the airlock hatch on the last U.S. spacewalk back in 1985, and he will open it back up on the next spacewalk, STS-37's CETA experiment.

Mission Specialist Linda Godwin N5RAX joined NASA in 1980 as a flight controller and payloads officer for several shuttle missions. Before joining NASA, Dr. Godwin, a rated private pilot, taught physics at the University of Columbia in Missouri and received several assistantships to conduct research in low temperature solid state physics. Selected by NASA in 1985, Dr. Godwin became an astronaut. She has worked with flight software verification, mission development, deployable loads, and Spacelab payload integration. STS-37 will be her first spaceflight.

Mission Specialist Jay Apt N5QWL worked for NASA's Jet Propulsion Laboratories in Pasadena, California, from 1980–82 in their Earth and Space Science Division as a scientist for the Pioneer Venus mission. In 1985, he became an astronaut. During his early days as an astronaut, one of Dr. Apt's jobs was to set up crew procedures for deploying and repairing GRO. He was lucky enough to get assigned to deploy GRO as his first shuttle assignment.

Compared to earlier shuttle ham experiments, STS-37 mission activities are more flexible. Since it isn't a Spacelab mission, the crew will wake and sleep at the same time, instead of working on different shifts. With a more relaxed schedule, the crew will have more time to take in the view, and hopefully, more time to operate SAREX. With an all-ham crew, it's possible that SAREX will be operated almost continuously in either voice or packet mode.

Based on a preliminary flight plan with an April 8, 1991 launch date at 14:14 GMT, the *Atlantis*'s orbital parameters will be:

Shuttle#	STS-37
Element Set	JSC-002
Epoch	91098.6250
Inclination	28.4632
RAAN	240.1995
Ecc	0.0006984
Arg Perigee	279.2831

Packet with the Microsats

The secrets of success.

by David Medley KI6QE

Many of us have had problems understanding the new microsat technologies and putting the hardware together to ensure success.

This is the account of one old ham who has achieved success through dogged determination and the old ham approach of trying something until you find out what works. Another approach is to ask an expert, but sometimes it's difficult to find the right expert. Here are some hints to help you get the most out of orbiting packet!

The specific equipment covered here is probably typical of many ham shacks. The transceiver is a Yaesu FT-736R with a PK-232 TNC, and a TAPR PSK modem and disconnect. The antenna system is a homebrew quagi driven by a Kansas City Tracker and an old IBM PC/AT.

Receive UO-11 Telemetry with your PK-232

This simple modification will allow you to copy the telemetry text directly from the University of Surrey's UoSAT-OSCAR 11.

UO-11 downlinks its telemetry via 1200 baud ASCII with an inverted bit format on 145.825 MHz FM. Reinhardt Richter DJIKM came up with a modification to the PK-232 which will receive this format.

The modification consists simply of using an unused inverter in the PK-232. You install a small switch to move this in and out of the circuit. See Figure 1; the procedure is as follows:

1. Solder a jumper wire between U-15, pin 6, and U-15, pin 1.
2. Break the circuit board trace connecting U-15, pin 6, and JP-4 at "A."
3. Mount an SPDT switch on the front panel. The right-hand side above the power switch is suggested.
4. Connect the center of the switch to JP-4.
5. Connect one side of the switch to U-15, pin 2.
6. Connect the other side of the switch to U-15, pin 6.

When the newly added switch is in one position, the PK-232 will receive normally. When it's in the other position, all data received by the PK-232 modem will be inverted before reaching the 8530. This is essential for receiving UoSAT 11, and you will need to make some parameter changes to the PK-232 as follows: **MODE ASCII, ABAUD 1200, WIDE ON, MFILTER $80,** and **AFILTER ON.**

The AFILTER is only available in PK-232 units with the 1989 firmware. If your unit does not respond to the AFILTER command, just ignore it. It will still work fine with the UoSATS.

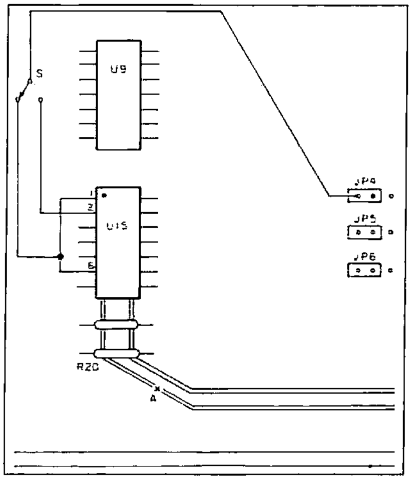

Figure 1. PK-232 modification for UoSAT-11 telemetry reception.

The TAPR PSK Modem

This sophisticated little unit comes from Tucson Packet Radio in kit form. Except for a few exceptions noted below, the instructions are well-documented and clear.

If you follow the instructions carefully, the unit should work. However, there are a few points to consider.

Because all the packet microsats use Manchester coding for the uplink, the left-hand switch on the modem must be "up" in the MAN position.

Next, the loop-back tests on page 40 of the instructions are merely to confirm that the Manchester circuitry is functioning. Do not infer from this test that the loop must lock at 9600 bps when receiving satellites. This is simply not the case; the loop always locks at 12.8 kHz when in the operational mode.

This misunderstanding is compounded by an error on page 41 of the TAPR instructions. The sixth instruction reads, "With a frequency counter at TP2, adjust R80 for a reading of 12.8 kHz." As R80 merely sets the internal clock in the modem, you can turn it all day without effecting the frequency at TP2!! If you substitute R33 for R80 in the instructions, all becomes immediately clear. Do not touch R80 under any circumstances once you have set it in accordance with the instructions on page 31.

If you are still having difficulties with these adjustments and loop-back tests, try changing the 4046 PLL chip at U-6. Of those tried, Motorola's 4046 chips have been the most successful. You can get them from JIMPAKS, Radio Shack, or electronic parts supply houses.

When adjusting the AFC "dead band" as described on page 31, be careful to get this as accurate as possible. Remember that the FT-736 will track in 10 Hz steps, so you don't want the "dead band" to be too wide. 25–30 Hz has been found to be a good choice. For the FT-726, this needs to be wider to accommodate the 25 Hz steps. If the modem tracks with the tune indicator not centered, try small adjustments to R61 while copying live data from a satellite, and recheck the "dead band." Best operation is obtained when the TAPR modem loop is properly centered.

When wiring the modem, you'll be asked at specific points to decide whether your unit is a TNC-1 or a TNC-2. The PK-232 has the same clock arrangement as the TNC-1. Especially note page 23 of the instructions. Be sure the orange wire is connected to pad 2 if you are using a PK-232.

The interconnection cables are straightforward—if you can call putting on DIN connectors and 8-pin mike plugs "straightforward"!! Follow the instructions for the FT-726R on page 44 and be sure you make up the cable to connect between the modem TNC audio outlet and the PK-232 radio outlet. When completed, you should have the following connections:

1. From TNC Data to the modem disconnect.
2. From TNC Audio to the radio 1 (or 2) outlet on the PK-232.
3. From the VHF and UHF connectors on the modem, a single 6-conductor, shielded cable connecting to an 8-pin mike plug and a phone jack on the front of the FT-736. The connections for the 726 are similar.

When putting on these connectors, hold the connector body in a vice, as you need both hands free for the job. Avoid too much heat, which can damage the insulating material on the connectors. If you use the high-quality DIN connectors supplied by TAPR, the cable will fit tightly inside the rubber boot. A little petroleum jelly on the cable solves this problem nicely.

Before actually trying to receive live material off the air, it's useful to try the system out with an audio tape. You can get one from AMSAT at a modest cost.

The most useful is one which has AO-13

Microsat Frequencies

Microsat	Downlink	Uplink	Comments
UO-14	435.070	145.975	9600 bps FSK (FM) up & down
(UoSAT-14)			1200 bps AFSK (FM) up & down
AO-16	437.026	145.900	1200 bps BPSK (SSB) down
(PACSAT)			
	437.051	145.920	1200 bps AFSK (FM) up with AX.25 Manchester encoding
	2401.143	145.940	
		145 960	
DO-17	145.825	None	1200 bps AFSK (FM)
(DOVE)	2401.22		
WO-18	437.075	1265 ATV	1200 bps BPSK (SSB) down
(WEBERSAT)	437.102		Fast Scan Video up
LO-19	437.125	None	CW Beacon
(LUSAT)	437.126	145.840	1200 bps BPSK (SSB) down
	437.154	145.860	1200 bps AFSK (FM) up
		145.880	
		145.900	
FO-20	435.910	145.850	1200 bps BPSK (SSB) down
(Fuji-OSCAR)		145.890	1200 bps AFSK (FM) up
		145.910	

telemetry on one side and Fuji-OSCAR transmissions on the other. The AO-13 material is not germane to this discussion, but the Fuji material is of considerable value. Feed the output of the tape recorder directly to the phone plug on the cable going to the modem.

Fire up the PK-232 and you should be receiving FO-12 material without any trouble.

The Right Settings

Now we are ready to get on the air. The first thing to do is to re-configure some of the parameters in the PK-232. The following has been found successful: **DWAIT 32, FRACK 6, FULLDUP ON, HEADERLN ON, MAXFRAME 2, PACLEN 32, PACTIMINT 10,** and **TXDELAY 64.** On the TAPR modem, the left-hand switch is "up" or on MAN, and the next, center. Then the next is "up" or ON, and the right-hand switch is "up" or JOINT. Set the audio gain control on the radio so that the left-hand bar display on the modem is around the 7th or 8th bar. Tune in the microsat downlink until the right-hand bar display indicates that the loop is centered. (When you were adjusting the modem, you determined which bar would indicate this.) An oscilloscope connected to the PK-232 is a great help, and if you have a suitable one you might consider leaving it as part of the permanent installation. I use a Kenwood SM-220.

Put the loop-centered switch in the STEP switch to either USB or LSB, depending on your receiver tuning. Use whichever setting tracks correctly. The loop should remain centered throughout the satellite pass, and should not flicker either up or down. If it does, your "dead band" is too wide.

If all is well, you should now be receiving the downlink perfectly. First, try connecting to your station through either Pacsat or Lusat. For example, **KI6QE V** LUSAT-1. Keep the transmitter output to 20 watts or less, and use the FM-N position on the FT-736. If you are using an FT-726, be sure the deviation is less than 3 kHz. You should connect almost immediately. Be sure you are using the correct uplink frequency; see the table. You don't have to track the uplink frequency for Doppler since the microsat has sufficient bandwidth to compensate. However, if you are a purist, you may want to adjust the uplink frequency at the beginning, center, and end of the pass to maintain continuous connect.

Now you can try FO-20. First, tune in the downlink as before on 435.910 MHz, then try to connect with the Mailbox. Use the callsign 8J1JBS. Please note that there is no digipeater, so do not try to connect to yourself. It won't work. When you get the connect, wait for the prompt **JAS>**. If you issue a command before this, you'll get frame-reject responses, and you'll have to disconnect and start again. Pressing **H** will bring a short help screen, and you can go from there.

All these packet microsats have four uplink frequencies. You can select the appropriate uplink frequency in accordance with the following formula, suggested by HB9AQZ to avoid congestion on the uplinks: 1. If your callsign ends in a letter from A-G; 2. if your callsign ends in a letter from H-M; 3. if your callsign ends in a letter from N-T; and 4. if your callsign ends in a letter from U-Z.

Now, a word about the FT-736 radio. It has a small jack on the back that short-circuits most of the audio processing circuitry. This DATA IN/OUT jack is well worth using for the FM data input from the PK-232. Instead of connecting from the TAPR modem to pin 8 on the mike connector, take it to the sleeve of a miniature stereo connector and plug this into the above jack. Don't forget to include a ground connection as well.

You will be surprised at the improvement in your uplink performance. Connection is usually achieved at the first or second attempt, and through-put is as good as or, in many cases, better than with the local terrestrial BBS. You can even do better than this by taking this connection directly to the junction of R32 and C39 in the TX unit of the 736, but unless you are willing to get into your new and expensive radio with a soldering iron, I suggest that you forego this dubious pleasure, and put up with the "substandard" performance as described above.

The Software

A number of packages are available. Most of us start with a simple communications program, such as PC-TALK or PROCOMM, to interface the computer and the PK-232. This is adequate and flexible, but you have to set things up and remember key commands. PC-PAKRATT from AEA conveniently automates most of the functions you need, but it's hard to modify, and it hasn't been updated for the latest developments.

For example, if you want to use KISS or some of the newer commands, you have to resort to dumb terminal mode, which has no real advantage over the simpler communications programs above.

A newer shareware program called LAN-LINK retains most of the automation of PC-PAKRATT while keeping the flexibility of the simpler programs. You can obtain this from many BBSs and CompuServe.

The Quagi System

The installation described uses a dual home-brew quagi system with 2 x 9 elements on 2 meters, and 2 x 16 elements on 70cm with auto tracking, as already indicated. Others have obtained perfectly satisfactory operation with vertical antennas for both transmit and receive. If you choose to go this route, be prepared to put more RF power into the antenna; you'll need at least 100 watts EIRP. If reliable performance is your goal, experience indicates that perhaps 200 watts EIRP is a better figure.

Finally, what about all that neat telemetry that pours onto our screens? What does it all mean? It's a running commentary on the health of the satellite. There are programs to decode this data into more meaningful numbers. A program called TLMDC is available from some BBS facilities as well as from AMSAT. This decoder requires your PK-232 to be in KISS mode to operate properly. TLMDC takes binary data from the downlink and writes it directly to disk, or decodes it to the screen or another disk file. KISS is available on all PK-232 machines. However, if you don't have the 1989 firmware, you need to change the following parameters to get into the KISS mode: **KISS ON, HPOLL OFF, PPERSIST ON, RAWHDLC ON, CONMODE TRANSPARENT,** and **HOST ON.** If you have the 1989 firmware in your PK-232, all you have to do is type **KISS ON** at the CMD prompt.

As soon as you have entered these parameters, exit the communications program and bring up TLMDC by typing **TLMDC COM1:1200,n,8,1.** You will be able to see the actual telemetry in meaningful numbers.

Another program, WHATS-UP, is available from Joe Kasser G3ZCZ at P.O. Box 3419, Silver Spring MD 20918. It doesn't require KISS, having its own communications program, and it's probably the best way to go if you are just starting up.

There are two land-line BBSs which carry AMSAT news and the software referred to in this article. The official AMSAT board is operated by the Dallas Remote Imaging Group at (214) 394-7438. In Southern California, the California Astronomers Group has a section in their BBS, phone number (714) 738-4331, for AMSAT; it carries the same material as the Dallas BBS. I'd be more than happy to assist you with problems in similar systems; you can write to the address below, but please send an SASE with your request.

Since this article was first prepared some dramatic new developments have taken place in the Microsat World. Both LUSAT (LO-19) and PACSAT (AO-16) have new BBS software loaded and operating. To take advantage of these very advanced technology satellites you will need the following software packages in your ground station. These are obtainable from AMSAT.

PB.EXE This program allows you to copy broadcast bulletins, etc.

PG.EXE This allows you to get a file directory and to up and download files.

PFHADD.EXE This prepares files for uploading. You cannot upload without first using this utility.

PHS.EXE This processes downloaded files and allows you to display their contents.

It is important to note that PG requires your TNC to be in the TRANSPARENT mode, whereas PB requires KISS mode. This causes PK-232 users some inconvenience in switching from one program to the other whereas if you are using a TNC-2 this is not so.

This is a fast developing field so keep your eyes on the AMSAT Bulletin Boards. In particular, watch the 75-meter nets on Tuesday evenings on 3.840 kHz.

David Medley KI6QE was first licensed in Australia as VK3MJ in the '30s. He emigrated to this country with his family in the early '60s to work for the Collins Radio Company in Dallas, Texas. He retired in 1987. You may contact him at 1450 Bayview Heights Drive, Los Osos CA 93402. Again, please include an SASE.

Weather Satellite Reception

Dust off your unused scanner.

by John E. Hoot N6NHP

A number of years ago I became interested in receiving images from weather satellites. There are plenty of articles on this topic, and manufacturers of inexpensive computer systems for displaying vivid Earth images, but few tips on receiving the birds. After reading some of the NASA and NOAA specifications from the satellites, I concluded that none of my current gear was going to be satisfactory.

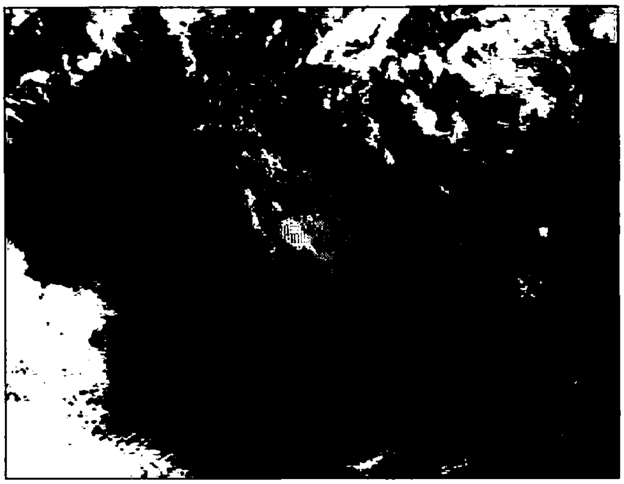

Photo A. With a little work, you can modify a used scanner to pick up the weather satellites.

Circumpolar Satellites

Polar orbiting satellites broadcast FM signals on frequencies between 137 MHz and 138 MHz. The problem for me was that these satellites have a total deviation of 30 kHz. Then, add to this, ±3 kHz of Doppler and transmitter stability guaranteed to about ±3 kHz. I figured I needed an IF about 42 kHz wide to do the job.

The calculated IF bandwidth meant that my NBFM receivers would be badly over-deviated. Any signal audio would be badly distorted and break up. With WBFM equipment, the weak signals would be lost in the noise. Despite the analysis, my curiosity led me to set my NBFM scanner to listen for the satellites.

As my analysis predicted, when I got the signal, it was over-deviated. The brighter the image transmitted, the higher the modulation index and the noisier the signal. But there was enough promise in that to get me thinking.

IF Discovery

I tuned a better receiver up to the same frequency, and to my surprise, the audio was worse. After some reflection, and a little time with a scope on the bench, I had the answer. The sharper IF filters in the good radio were attenuating the wide signal more than the cheap scanner I used initially. I sat down with a block diagram of the scanner to see what I could do to widen the IF for weather satellite work. The problem turned out to be pretty easy to solve. I discovered that with a little work, most synthesized scanners can be modified to perform well as weather satellite receivers.

Figure 1 shows how most modern, keyboard programmable NBFM scanners have been designed. You can often pick up a working unit at a swap meet for under $75. A new unit may only set you back $125. And, as I indicated, it only takes a little work to make it perform as well as dedicated satellite receivers that cost five to ten times as much. It's best to convert a lower-cost scanner with just NBFM capability since the more expensive units already have wideband FM (although they are too wide) and will not perform well after modification. If your scanner already has wideband FM capability, just add a good preamp for reasonable performance.

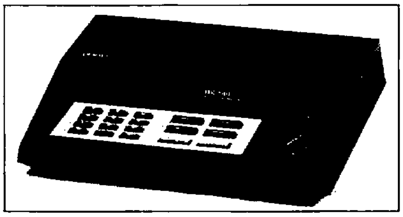

Photo B. The Uniden BC-145 scanner modified for weather satellite receive.

The Scanner Modification

Most scanners are dual-conversion receivers. They have two RF front ends: one dedicated to UHF reception and the other to VHF reception (see Figure 1). After the RF stages, both signals are mixed with signals from the PLL-controlled oscillator to produce a 10.7 MHz IF signal.

Using an analog multiplexer, the microprocessor selects which of the mixer outputs to feed through to the rest of the receiver. Since we are only interested in 137 MHz signals, we only need to worry about the VHF section.

Typically, the scanner uses a simple crystal filter at 10.7 MHz. Check the specifications of your unit's filter; refer to the part number. Most of these crystals are designed for WBFM gear, so they will have a 3 dB bandwidth of ±120 kHz. As long as the filter has a bandwidth of ±25 kHz or more, you won't need to replace it. If you do have to replace it, you can easily find a replacement in a junk FM broadcast receiver or you can order one from an electronic supplier for a few dollars. Suitable units include Tokyo America SM07M3-A0-20 from Digi-Key for $2.10.

After the first IF, the receivers will have a second local oscillator that will mix the 10.7 MHz down to 455 kHz. After the second mixer, you'll find a 455 kHz ceramic lattice filter. This component narrows the bandpass of the FM. These filters typically are ±10 kHz with very sharp skirts. If the first IF crystal filter is narrow enough, this filter can be removed and replaced with a small value (0.01 μF) bypass capacitor. Alternatively, you may wish to replace it with a wider ceramic filter. Suitable units include MuRata Erie CFM455A for about $13.

As a specific example, I've modified a Uniden BC-145 scanner. The 455 kHz ceramic filter is a Murata SFR-450D. It's an orange colored device labelled "part number FT-2," sitting next to the MC3359P IC. I removed this filter and replaced it with the 0.01 μF capacitor as shown in Figure 2. If you have trouble finding which are the in and out leads for you filter, just trace the leads from pins 3 and 5 (input and output) of the MC3359P.

Sweeping Up

Once you have replaced or bypassed the second IF filter, you will need to realign the

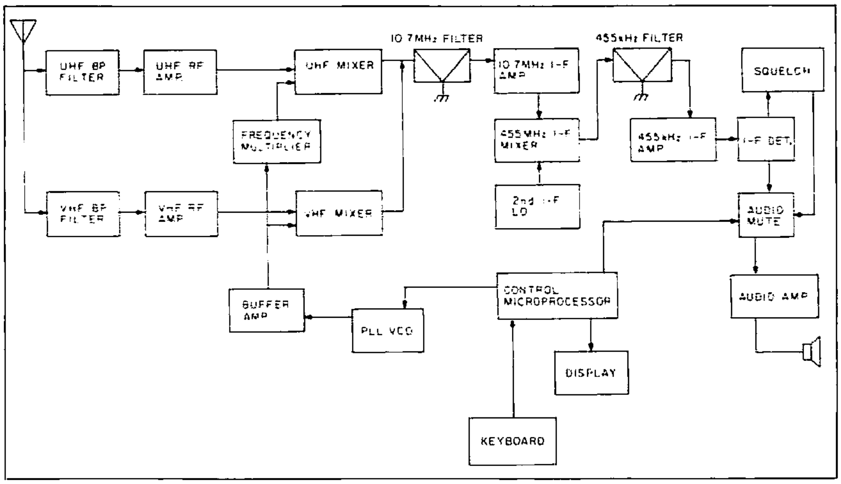

Figure 1. Generic FM scanner block diagram.

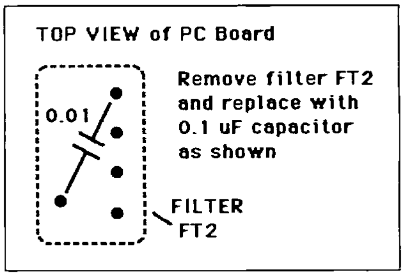

Figure 2. Pinout of the Murata SFR-450D filter showing the in and out pins. Remove the filter and replace with a 0.01 μF capacitor where shown.

receiver. If you have a sweep generator, you can set the bandwidth to ±22 kHz, and adjust the IF transformers for flat response over the new passband.

If you don't have a sweep generator, do not despair. Get a 2 meter handheld and run it into a dummy load near the scanner. Since every scanner I have seen that covers 137 MHz FM also covers 2 meters, you can use the HT as a signal generator. Program the handheld in kHz steps to 144.500 MHz through 144.550 MHz. Stepping through the memories while transmitting is nearly as good as a sweep. You do not even need a scope. An RF voltmeter or oscilloscope connected to pin 5 of the MC3359P is good enough for the alignment. Again adjust the IF for a flat response across the desired passband. In the case of the Uniden BC-145, just tune L5 and L6 in the first IF stage slightly until you achieve the desired bandwidth.

After the adjustment, you should find that the satellites give good clean signals throughout their passes. Also, the scanner still functions reasonably well with NBFM signals, since a strong signal will force out adjacent signals.

You can also receive WEFAX from GOES and METEOSAT geostationary weather satellites by using a converted scanner with a 1691 MHz to 137 MHz downconverter.

If you're tired of listening to police calls, or have a dusty scanner lying around, put it to a new use. Spend an hour on this project, and be ready to chase down some impressive satellite images. [*Ed. Note: A completely modified and aligned Uniden BC-145 scanner as well as a lineup of IBM PC interfaces and programs for FAX, RTTY, SSTV and weather satellite receive are available from the author.*] 73

FEEDBACK

In our continuing effort to present the best in amateur radio features and columns, we recognize the need to go directly to the source—you, the reader. Articles and columns are assigned feedback numbers, which appear on each article/column and are also listed here. These numbers correspond to those on the feedback card opposite this page. On the card, please check the box which honestly represents your opinion of each article or column.

Do we really read the feedback cards? You bet! The results are tabulated each month, and the editors take a good, hard look at what you do and don't like. To show our appreciation, we draw one feedback card each month and award the lucky winner a free one-year subscription (or extension) to *73*.

To save on postage, why not fill out the Product Report card and the Feedback card and put them in an *envelope? Toss in* a damning or praising letter to the editor while you're at it. You can also enter your QSL in our QSL of the Month contest. All for the low, low price of 25 cents!

The Desert Voices Project

An overnight success story.

by Linda Reneau KA1UKM

At a de-commissioned NIKE missile site about 35 miles southeast of Minneapolis, Minnesota, station AAR5NSF of the Desert Voices project is busy handling phone patches, packet BBS messages, and MARSGRAM communications between U.S. Service people and their families and loved ones in the Middle East. The U.S. Army has recognized the Desert Voices project as an officially sanctioned Army MARS station operating under the guidance and authorization of the CONUS (Continental U.S.) MARS Director Tom Moore in Ft. Ritchie, Maryland.

Edward Addy KEØEG, owner of NW Antenna & Communications in Minneapolis, first conceived of the Desert Voices project last October. By the first week in November, people and resources were coming together so quickly that, according to MARS Digital Communication Coordinator Paul Ramey WGØG, one of the biggest challenges was to make sure that everything was being put together in an orderly way. "All we had to do was say, 'We need it,' and someone would come forward with it."

Although thousands of hours went into the acquisition of equipment and renovation of the site—painting, rewiring, construction of operating positions, and installation of the multiuser LAN computer system—Ramey WGØG says it "came together overnight." Addy KEØEG, who designed the antenna system and communications center, gave much of himself, both financially and personally, Ramey said. When Addy presented his plans to other businesses, the donations quickly started rolling in.

The U.S. Bureau of Mines provided the lease for the 34-acre site and the buildings. Unused for 20 years, it took many hours and materials to get the main building in shape. Local businesses freely donated "all the right stuff" to repair, repaint, rewire, and upgrade the old building's heating and electrical systems. Other businesses provided electrical power, telephone service and FAX time, carpentry skills, furniture, graphic and printing services, video documentation and training materials, and office equipment.

Well-Equipped

Regional Sales Manager Mike Forsyth of Kenwood U.S.A., who first let *73 Magazine* know about the Desert Voices project, says that Kenwood has supported the project with thousands of dollars worth of radio equipment. "We couldn't have gotten on the air so quickly without their help," said R. Hugh Beebe WL7AIT, MARS Liaison for command and control. Other contributors include: AEA Electronics, four TNCs; D.F. Countryman of St. Paul, RF patch panel material, connectors, and RG-8/U coaxial cable; and A&C Metals of Blaine, Minnesota, heavy duty antenna mast material.

From outside the facility, you can see two full-size rhombic antennas for transmitting phone patches, two 4-element 20m monobanders and one 6-element monobander for 15m HF operation, a 40m dipole, and VHF antennas. Northeastern States Power Company provided the materials and crew to install the 547′ x 250′ rhombics on eight 105′ tall power poles. They also donated 8000′ of #2 solid copper wire. Without these antennas, Desert Voices would not be able to achieve reliable communications with the Middle East some 6500 miles away. Delmar Land Surveyors surveyed the exact location to make sure the antennas were correctly aligned.

St. Paul Tower constructed a 120′ tower between the two rhombics. Later, they will install six antennas for communications with other MARS stations throughout the U.S. Mirage/KLM has donated three special beam antennas for this tower, and Telex Hy-Gain is providing a rotator. Technical Materials Corp. of Mamaroneck, New York, provided low-loss, high power, precision antenna balun transformers and terminators for the rhombics.

The project actually comprises three complete radio station systems at the Desert Voices site. By the third week in January, the second station will be complete and the phone-patch capacity will rise to 1000 per day. It will be one of the four largest MARS relay stations in the world.

A Priceless Service

Desert Voices radio station AAR5NSF went on the air December 13, 1990. Within a month, it had handled over 600 phone patches and 400 packet communications. It is directly interfaced to the gateway MARS stations on the East Coast and serves as an alternate gateway, or relay, station for Army MARS. Thanks to volunteers from the Civil Air Patrol, the military (both active and reserves, including the Minnesota National Guard), law enforcement agency dispatchers, and—of course!—the amateur radio community, the Desert Voices station operates around the clock, seven days a week. There are four radio operators on duty at all times.

Ramey WGØG says that about 150 hams have assisted the project in some way, and Addy KEØEG confirms that 93 hams are currently on active duty at the station. "They're doing a tremendous job," Addy says. And Ramey: "It didn't take any arm-twisting." Most importantly, says Ramey, the ham community's speedy response to the call for help proves that hams are "a reliable resource for their country." They have freely given of their time, knowledge, and skills. Some have donated money or equipment. At Desert Voices, radio operating skills and techniques, learned in fun, are put to serious, disciplined use to provide a service that "you can't put a price on," says Addy. How much is it worth to a mother, father, spouse, or friend to get in touch with a loved one who is in an uncertain and potentially dangerous situation? R. Hugh WL7AIT adds that Desert Voices is not representing any political opinions about the situation in the Middle East. "We're providing a human service."

Ready for the Future

All the staff interviewed at Desert Voices agreed that there are few activities more satisfying than using your abilities to benefit others. The amateur radio operators at Desert Voices are gaining that unique fulfillment you get from knowing that you have ability, and are able to use it skillfully.

Addy KEØEG reminds us that one of the basic purposes of maintaining the Amateur Radio Service is "to provide a pool of trained radio operators" for the country for emergency communications. Entrusted with valuable radio spectrum for their personal use, there is nonetheless the expectation that hams will be useful when the need arises. Ramey says the response shows that hams are willing and eager to "give something back" to the country that supports the continued existence of their hobby.

In his letter to Kenwood, Hugh WL7AIT wrote that upon return of the forces from Saudi Arabia, "we envision the equipment at the Minnesota site to be returned for further humanitarian support missions that may be encountered in the future." At that time, the site itself will be returned to the Minnesota National Guard; however, MARS personnel and members will be ready to step in to provide emergency communications whenever it again becomes necessary. Hopefully, there will always be plenty of hams who, for the sheer love of radio communication, will be ready to do their part, too.

Author's Note: Let us know when you, or someone you know, is involved in activities helpful to the country, community, and world. Sure, you'd rather stick by your rig in

Elementary Mode S

Satellite fun on 2.4 GHz–the easy way!

by Ed Krome KA9LNV

The launch of the Microsats has provided some really interesting opportunities for experimentation in both operating modes and frequencies. The digital modes include PSK (Phased Shift Keying) from 1200 baud (PacSAT and LuSAT) to 9600 baud (UoSAT 14), 1200 baud packet AFSK (Audio Frequency Shift Keying) (DOVE), digitized pictures (WeberSAT), and a digi-talker (DOVE).

If this isn't enough to make any experimenter think he's in heaven, there are also three different frequency schemes in use. The most common frequency combination is Mode J, with a 2 meter (145 MHz) uplink (Earth to satellite) and a 70cm (435 MHz) downlink (satellite to Earth). The active digital repeater/mailbox satellites, PacSAT, LuSAT and UoSAT, use this scheme. DOVE's main transmissions are on the 2 meter band, as this satellite was designed for easy reception in classrooms using a minimal ground station.

Two of the satellites (PacSAT and DOVE) also incorporate a third downlink frequency as a beacon: Mode S, which operates in the 13cm band. Way up there. Yeah, 2400 MHz. What, you don't have any 13cm equipment? That's not hard to believe, since that is the lowest band for which there is not a single piece of integrated commercial equipment available. No plug-in modules for the Yaesu FT-736, either. But the band is there, part of our amateur allocation, and alive and well. OSCAR-13 has a full transponder for Mode S, allowing QSOs with a 70cm uplink. And various areas of the country have terrestrial activity in a different segment (2304 MHz) of the band. There is even EME (Earth-Moon-Earth) activity up there.

While this is more of a "how to" than a pure construction article describing 13cm receiving equipment, I have included "benefit of experience" construction techniques on some commercially available kits. And, for the more adventurous types, I have included construction information for a 13cm antenna.

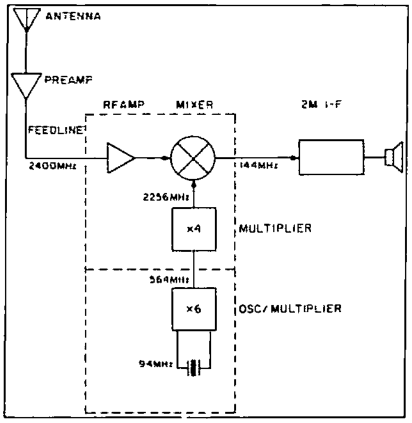

Figure 1. Basic 2400 MHz receiving converter.

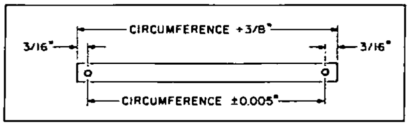

Figure 2. Loop yagi element dimensions.

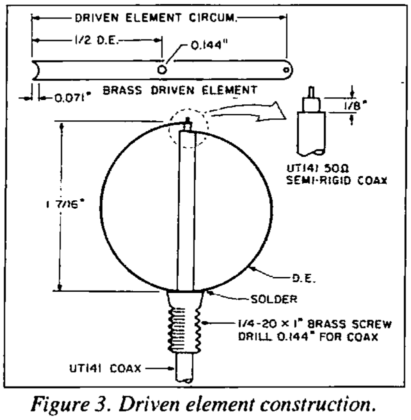

Figure 3. Driven element construction.

Mode S and How to Get There

Becoming active on the downlink end of Mode S has the same requirements as any other band: an antenna to catch the signal and a receiver to hear it. On the higher VHF and UHF bands, the receiver part of this recipe is usually handled with a two-part approach. A converter changes the VHF or UHF signals to something more manageable, which is then fed to an HF or VHF receiver. In this manner, one good HF or VHF receiver (or transceiver) can be used for many bands by merely adding the appropriate converter. In my own station, my integrated receivers and transmitters are all HF stuff, good only to 30 MHz. And they contain lots of vacuum tubes, too. Converters do everything beyond that, and sometimes converters get plugged into converters. This works fine.

Coming up with a receiving converter for 13cm presents some interesting problems. A basic 13cm converter, like any other superheterodyne device, consists of three parts: an RF amplifier chain, a local oscillator, and a mixer. Because antennas and converters are usually separated by some distance and coupled by some sort of (lossy) feedline, standard practice is to divide the RF amplifier section of the converter into two separate parts: the converter proper, and a second part of the RF amplifier chain, called a preamplifier, mounted as close as possible to the antenna. (See Figure 1.) While preamps can't compensate for an inadequate antenna, they can do wonders for high loss feedlines. And they get better as the frequencies get higher. A very low noise preamplifier mounted close to the antenna will amplify the desired signal as well as the background noise. At frequencies above 432 MHz, background noise from the sun, sky, etc. is quite low, so you amplify a lot of signal and not much noise. The cable connecting the preamp to the rest of the converter merely attenuates the desired signal, but it attenuates any accompanying noise with it as well.

Within limits, the all-important signal-to-noise ratio is mostly preserved, even from a long run of pretty lousy cable. If you mounted that same very low-noise preamp after a run of cable, the preamp would be amplifying a signal attenuated by the loss of the cable. The signal-to-noise ratio would be lower, and once signal is lost, it's gone forever. It doesn't matter how much gain you add, you just amplify noise. And any cable becomes lossier as the frequency goes up. For example, a 100-foot run of Belden 9913 may have only 1.6 dB loss at 144 MHz, but it has over 10 dB loss at 2400 MHz. Extremely good coax can minimize this, but have you priced ⅞" Andrews Heliax hardline and connectors

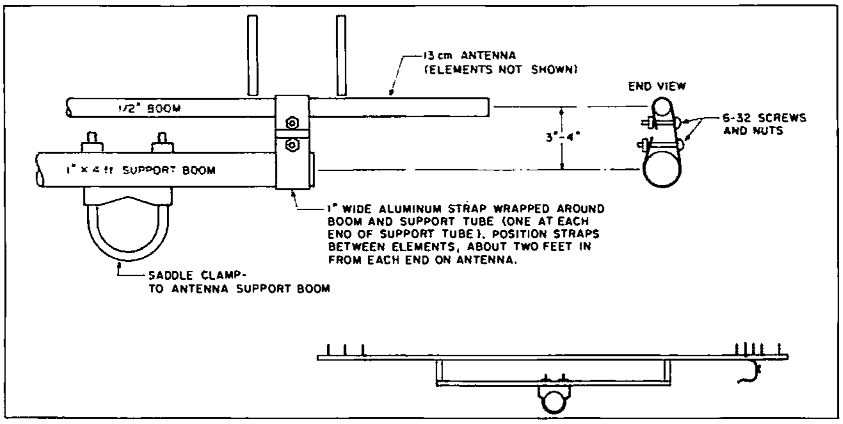

Figure 5. 13cm antenna and support assembly.

lately? Preamps are much cheaper.

Current technology in low-noise, high performance preamps uses GaAsFET (Gallium Arsenide Field Effect Transistors) devices. SSB Electronic and Down East Microwave manufacture good preamps. Later on in this article I'll detail a home-constructed device that offers good performance at a reasonable cost.

Since we have been working from the back end forward, the last part of the Mode S equation is the antenna.

Among EME types, the parabolic dish is the only way to go. The rest of us have really only two readily reproducible designs to work with, the loop yagi and the helix.

The Yagi-Uda (usually called simply "yagi") type of antenna, with many near half-wavelength parasitic elements, is the most common design at VHF and lower frequencies. Element lengths get unmanageably critical at 23cm and above, so yagis have mostly been replaced by the loop yagi. Loop yagis were originally developed by Mike Walters G3JVL and replace the yagi's straight elements with near full-wave loops made from strips of aluminum. Construction tolerances are still tight, but manageable. One of the best parts of a loop yagi is the driven element feed system. No balun is required, just a solder-it-together brass loop element on a piece of feedline. And it is at DC ground, which provides static electricity protection for your equipment. You can buy loop yagis in kits or ready-made (from Down East Microwave), or you can "roll your own."

Available Hardware

A review of available receiving equipment for Mode S shows both kits and built-up converters and preamps available from SSB Electronics and Down East Microwave. Down East Microwave also has antennas and carries the SHF Systems line of "no-tune" converter kits and built-up units.

Homestyle—Almost

Now let's look at what it takes to get a real working station going on Mode S, home-construction style. The problem with 13cm limiting equipment construction to a (very) few hard-core types can be summed up in one word: alignment. Once you build something, you have to get it working. Then you have to optimize it. To align a piece of receiving gear, you have to have something for it to listen to. But on 2400 MHz it is about as difficult to build a signal source as it is to build the converter it was intended to align. Remember "Catch 22"? Tricky, eh?

Recently, equipment has become available that is changing all that. Traditionally, converters and receiver front ends have consisted of myriads of sharply tuned circuits with trimmer capacitors and lots of interactive adjustments. Designs of this type are hard enough to get working at HF frequencies, and they get progressively worse as you go higher. The best alignment (and troubleshooting) device, the spectrum analyzer, is not a household appliance. In their quest for compact, reproducible UHF ham gear, several amateurs, among them Richard Campbell KK7B and Jim Davey WA8NLC, have developed a series of "no-tune" transverters. Honest. Only one possible adjustment in an entire transverter and that is in the local oscillator. That doesn't sound too bad, does it?

These no-tune transverters are based on two developments. One, the MMIC, is recent. The second, bandpass filtering using broadband printed hairpin filters, has been around awhile. MMIC's or Monolithic Microwave Integrated Circuits are truly incredible devices. Tiny and inexpensive, they are broadband gain blocks with fixed input and output characteristics. They don't oscillate or require any critical external components. They are typically 50 ohms in and out with low VSWR. With these devices, gain is so easy to get that it is no longer necessary to worry about whether or not you get gain from more ticklish circuits, such as frequency multipliers, or to worry about filter loss. Not enough signal at some stage? Add another MMIC. No problem.

With gain no longer a problem, the designers could do things like develop passive, no-tune diode frequency multipliers. Drive a diode into generating harmonics and select the one you want with filters. Anyone who has ever built VHF gear knows that the worst part of the whole mess is getting active frequency multipliers to work right. Ugh.

Easy, broadband gain also worked well

with the design of printed hairpin bandpass filters. Filters were designed with manufacturing tolerances taken into consideration to provide broad, flat passbands and steep slopes. Manufacturing irregularities which were once fatal now have little effect. These filters also have no tuning required, or even possible.

The entire no-tune transverter is available in two forms as kits from Down East Microwave. One version is a dedicated S-band receive converter (the SHF-2401K). The second is a transverter, which has the same receiver and also a 10 mW transmit section (SHF-2304). If you are going to build something like this anyway, get the transverter and help get more amateur activity on 13cm. Even barefoot, 10mW is adequate for local contacts. You can always add transmit power later. Remember, as amateur radio operators, we either use those frequencies or we may lose them. The commercial guys are always hungry for spectrum, and ours looks tasty. Both units use a 2 meter IF (Intermediate Frequency). *[Ed. Note: See the February 91 issue of 73 for a review of these kits.]*

Construction Hints

As the photos show, construction of these devices is straightforward. Build the local oscillator first. You must follow the recommended layout and use good construction techniques. Keep the leads short and solder the joints well. Be sure to ground the one pad that is noted as requiring through-the-board grounding. Also, pay attention to the orientation of the transistors and MMICs. The Avantek MSA-04 series has the dot on the output, while the MCL MAR series has the dot on the input. The total tune-up requirements are to tweak a 10 pF trimmer for maximum LO output. Photo A shows a complete and functioning local oscillator.

A common complaint deals with the difficulty of installing chip capacitors. To do this right, you need a small (15 watt) soldering iron with a small tip, tweezers, a toothpick, and a magnifying glass. The last item is a suggestion that I learned through experience. Since I passed a certain magic age, I find I can't see far away with my glasses off, and I can't see close up with them on. So I bought a set of Sears headband-mounted binocular magnifiers. These are only 2½ power, but they're perfect for getting parts in the right place.

To mount the chip caps (now that you can see them), first lightly tin one circuit board pad. Don't tin both or the chip may not sit flat on the board. Then place the chip cap where you want it with the tweezers. Hold it in place with the toothpick and remove the tweezers. Touch the iron to the pre-tinned circuit board trace. Flow the solder onto the end of the cap. Then solder the other end of the cap. Resolder the first end if needed to insure a good connection.

Construction of the converter board itself is probably even easier than building the LO (Local Oscillator). The hard part, at least on the early boards, is that you must use thin brass foil to connect the MMIC ground leads and several pads to the ground plane side of the circuit board. I found that the best way to ground the MMICs is to cut pieces of brass foil about ¼" long and as wide as the MMIC ground pads, then make a 90 degree bend back about 3/32" from one end. Slip the long end through the board hole from the circuit side (use the magnifiers to make absolutely sure that there are no shorts to the input or output pads), then hold it in place by putting an awl into the hole. This will form the brass to the hole at the top, allowing you to insert the MMIC down into the hole in the board, where it belongs.

While holding the foil in the hole with the

Boom: 8' length of ½" diameter aluminum tubing (do not use anodized tubing).
Elements: All elements are made from aluminum strips 0.25" wide by 0.032" thick.
Circumference: Distance between centers of 0.116 holes drilled in each element. Tolerance ±0.005". Each element is to be made approximately ⅜" longer than the specified circumference dimension to allow approximately 3/16" overlap between the ends of the element.

Table 1. Scaled from W1JR 13cm 52-element design.

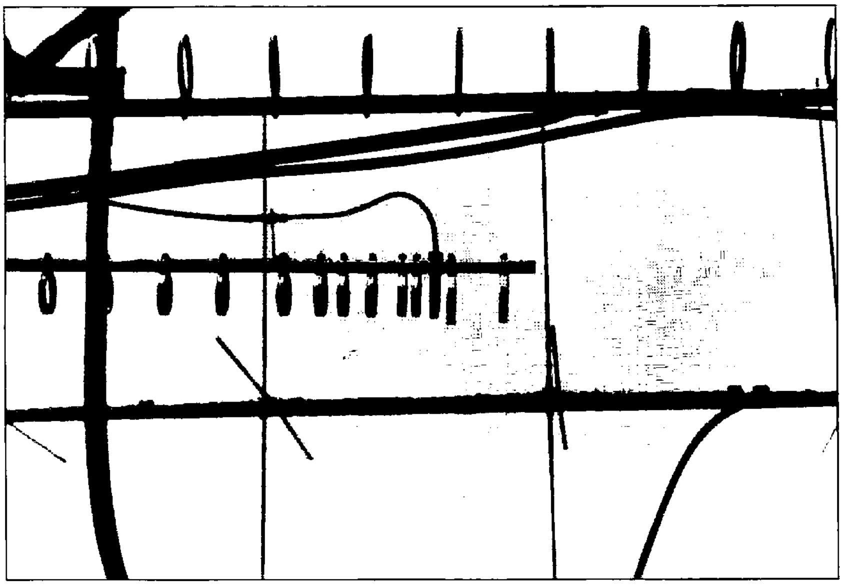

Photo D. 13cm loop yagi, mounted upside down, showing driven element detail and two reflectors. A 23cm loop yagi is on top, with a 2m cross yagi behind it. The T-shaped structure on the left is the power divider with hardline phasing lines for two 19 element yagis on 70cm.

awl, use your fingernail to spread the foil away from the hole and lock it into place on both sides of the board. A little experimenting will make it easy. Before you solder, inspect it carefully for shorts. Solder the top side lightly so the MMIC will sit flat on the board. Sometimes it is helpful to solder the pad, then clean it off with a piece of Solder-Wick™ desoldering braid. The resulting pad will now be well-tinned and easy to solder quickly.

Several pads on the converter board must be connected to the foil side of the board. One way to do this is to make slots in the board by carefully rocking an X-acto® knife blade through the board. The Teflon™ board material cuts easily. Then thread a strip of the brass foil through the slot, bend it flat on both surfaces, and solder it in place.

A suggested construction technique is to solder the MMIC bias resistors to the centers of the hairpin filter elements where possible. This improves stability. Photo B shows the routing on a complete transverter board.

Mounting the HP-2822 diode packs can be interesting. They are as small as chip capacitors, have three leads, and are surface mount devices. The same technique that works on the chip caps works here also. Tin one pad, position the diode pack with tweezers and a toothpick, then tack one lead. Then solder everything.

The initial results using this converter absolutely amazed me—it worked the first time I fired it up. I heard the S-band beacon on DOVE the first time I tried. Not bad.

A suggestion on improving the versatility of the converter: Wire it to work both commonly-used segments of the band. Remember about "use it or lose it"? The satellite subband is at 2400 MHz. Use of a 94.00 MHz crystal in the LO puts the Microsat S-band beacons (2401.221 for DOVE) at an IF of 145.221. A 90.00 MHz crystal will put the 2304 weak signal frequency at 144 MHz. Wire a small DPDT relay to the board to switch between the two crystals. Keep the leads short.

Preamp Construction

The next segment of the Mode S rig is the preamp. Fortunately, Al Ward WB5LUA has developed a series of no-tune preamps for the UHF bands, all the way to 10 GHz. These were detailed in *QST*, May 1989. Construction is easy, but for best results you must follow Ward's instructions. The 13cm version uses an ATF 10135 GaAsFET, and offers a less than 1 dB noise figure. While all the preamps were shown with grounded sources (which require separate gate bias supplies), the 13cm unit was also shown in a self-biased version. This means that there is no negative gate bias supply to fuss with, but you must ensure that the source leads are properly RF grounded.

Proper RF grounding of the two source leads is done by connecting them to very low inductance disk capacitors. The RF energy thinks the capacitors don't exist and that the source leads are really grounded, but there is no DC ground. So, self-biasing is accomplished by standing the sources above DC ground with a resistor.

Never content to leave well enough alone, I built two preamps and used slightly different construction techniques on each. On one unit, I drilled holes to fit the disk capacitors through the circuit board as instructed in the article, then grounded the capacitors underneath.

On the second I used a different technique. First, use the X-acto knife to make slots in the circuit board at the inside edges of the small rectangular pads on either side of the GaAsFET. Then thread ¼" wide strips of very thin brass foil through the slots. Flatten the foil to the board and solder it to both sides. Tin one side of a disk capacitor. Then position one disk capacitor properly (with the tinned side down), and heat the brass strip from the underside with a 40 watt iron. When the heat transfers through the foil, it will melt the solder and stick the capacitor in place. It is very easy to break a disk cap by excess pressure, so be careful. After mounting the disk caps, check them with an ohmmeter to insure against shorts to ground.

The circuit board is very flexible and bends easily, so make it more rigid before mounting the rather delicate chip devices. One way to do this is to bend or piece a ¾" wide by 0.016" thick hobby brass strip all the way around the circuit board. Leave ⅛" overlapping the bottom side of the board. Mount the connectors and feed-through on the strip. Then solder connectors and strip to the circuit board. Solder the board ground plane to the strip all around. Mount the chip components, zener diode and GaAsFET last. Doing the heavy soldering between the walls and board first not only physically protects the components from fractures induced by bent boards, it also keeps you from frying the chip components.

Kits are available from Down East Microwave. I built two of these, one with right-angle-mount N-connectors and one with end-launch SMA connectors, just like Ward suggested. Both work, but the SMA version (which has the brass foil source grounding straps) works better. This unit is shown in Photo C.

The Antenna

Last but not least is the loop yagi. The design I used was based on that presented by Joe Reisert W1JR at the first annual 1296/2304 Conference (19–22 September, 1985, in Estes Park, Colorado). His design was for 2304 MHz. Since I wanted to use the antenna on both 2304 and 2401, I did the unpardonable and scaled W1JR's element lengths to 2350 MHz. I did not change the element spacing. This antenna has 52 elements and fits on an 8' section of ½" diameter aluminum tubing.

One method of building this antenna is to get a sheet metal shop to shear a bunch of ¼" wide strips about 2' long from a sheet of 0.032" thick aluminum. Do not use anodized aluminum for the elements or the boom. Element lengths and spacing are itemized in Table 1. Scribe off the required lengths on the strips with a steel scribe point set of dividers. Adjust the dividers with a dial caliper and lay them off. Recneck each dimension. Tolerances are ±0.005", so be careful. Remember to leave 3/16" between the center of each hole mark and the end of each strip and ⅜" between adjacent holes on a strip. These will be cut apart later, as it is easier to handle a whole strip. After you scribe a length, mark the element number or group on it with a waterproof marker. Then, with a magnifying glass, center punch each mark accurately. Drill each hole 0.116 (#32 drill) in diameter. Drill them one hole at a time; stacking strips is a sure way to goof. Finally, cut the element strips apart.

Preform each element loop by bending it around a form. A piece of ¾" PVC pipe works fine.

To mark the element locations on the boom, it seems that millimeters are easier to use than inches, so I converted W1JR's dimensions. It's hard to find a tape measure that reads out in decimal inches! Lay a tape along the boom and mark each location. Dimensions are from the end of the boom. This prevents cumulative errors.

Drilling the boom squarely can be challenging. Eyeballing doesn't work. Use a "universal drill guide" with a V-notch designed to drill holes in the center of a pipe.

Before you start drilling, you must devise a method of preventing boom rotation while drilling, thereby keeping all the drilled holes in line. You must also support the boom high enough off the bench so that the drill guide can slide. One way to do this is to first drill a hole through the boom large enough to clear a 1½" long No. 4 or 6 wood screw. Run the screw into the bench only about ¼". The boom will now be free to move up and down as the drill guide is moved, but will be rotationally fixed. Two screws in different locations may be required if your drill guide has a large base and you can't get all the holes without hitting the screw. Slide the drill guide along the bench with the boom in the V-notch and drill each 0.116" hole. Remember to drill the driven element hole ¼" in diameter.

When assembling the elements to the boom, use 4-40 x ¾" stainless screws, nuts and lockwashers. Put the lockwasher between the nut and the boom, not under the element. Coat the ends of each element with a corrosion inhibitor such as No-Al-Ox™. Weather turns aluminum into aluminum oxide, which is a dandy insulator. No-Al-Ox is available from your local electrical supply house and well worth the nominal cost. Assemble the elements with the overlaps all facing the same direction.

For the driven element, drill a 0.144" (#27 drill) hole through a ¼" brass flat head bolt. Also drill the center of the brass strip driven element to 0.144." You must assemble all the parts (element, bolt, nut, boom, etc.) on the UT141 hardline before you solder things together. Use hobby (low-temperature) silver solder and flux for all outdoor connections as it does not deteriorate from weather like regular rosin core solder. A note: Go easy on the heat on the hardline. If you overheat it, it can swell and rupture. Then you start over. I did.

The finished product, or at least the driven element end, is shown in Photo D amidst a variety of other antenna goodies. Once again, complete antennas and antenna kits are available from Down East Microwave.

The 8' long, ½" diameter boom is flimsy and requires mounting support. The strap mounting method shown is easy and works. A single U-bolt through the support boom mounts the whole thing to the antenna cross boom. See Figure 5.

A note on antenna mounting: Many satellite operators use a nonmetallic cross boom between their antennas. This tends to cut down intermod problems on the harmonically related modes, such as Mode J. If you mount this (or any) antenna on an insulated boom and leave the preamp connected, remember where atmospheric static electricity has to go —down the lead in coax into the shack. Keep the coax disconnected from the equipment and thoroughly grounded in the shack when the antenna is not in use. Never use the antenna when thunderstorms are in the area. We are not talking about a direct lightning strike here either; there is little real protection from a situation like that. I strap-ground the 1296 and 2401 antennas right up on the mounting boom.

Results

Now the big question: Does it work? Since I do not have access to test equipment for this frequency, I took the pragmatic approach—I tried it. The first test was with the loop yagi connected to the no-tune downconverter through three feet of RG-142, 12 feet of RG-213 around the rotors, and 65 feet of 9913. And no preamp, as it wasn't built yet. But I heard the DOVE S-band beacon on the first try.

Since the addition of the WB5LUA no-tune preamp, the DOVE beacon is loud enough to hold the PLL (Phased Lock Loop) on my G3RUH PSK modem, and autotune the attached receiver. DOVE's 100 kHz Doppler shift makes this rather touchy sometimes, as a brief fade can cause the signal to run out of the capture range of the modem. Mostly it holds surprisingly well, considering that the rate of change of frequency fairly screams across the band.

This arrangement also works on the big guy, AO-13, Mode S. Downlink signal strength is marginal for SSB, but quite adequate for CW. However, perseverance has yielded a handful of sideband contacts on that mode, which is quite a thrill. Two hints are useful at this point. First, lots of multiplication (X24) between the LO crystal and the injection frequency offers the potential for large frequency conversion errors. It can be very difficult to predict where to initially find S-band signals. My own set-up has over 50 kHz frequency offset, exclusive of Doppler. The solution is to start by trying to find a loud, strong signal like DOVE and tune all over the place until you find it. Then track the signal, recording the apparent frequency and time and compare TCA (Time of Closest Approach, where the Doppler correction should be zero) to the published actual beacon frequency.

Second, the antenna described here is marginal at best for AO-13. The AO-13 13cm beacon is only a watt or so, and at times is 42,000 kilometers away! When you hear a Mode S signal, rock the antenna position to peak it. It is surprising how much difference this can make.

The advent of no-tune preamps and converters has brought Mode S into the realm of the average experimenter. Good construction practices and attention to detail are rewarded by excellent performance on frequencies previously considered almost unattainable. Now, go out and build some gear. See you on Mode S! 73

Touch-Tone Activated Scanner

So you won't miss a call!

by Don Moser AA7Y

Inexpensive, wide-frequency coverage scanners have been developed into valuable tools for the amateur radio operator. There are, however, two drawbacks that keep them from reaching their full potential. First, when you're scanning a number of busy repeaters and simplex frequencies, and Bert and Ernie tie up one repeater, your scanner will most likely be stuck there. If someone tries to call you on another frequency, you won't hear the call. Secondly, you (and the rest of your household) will have to listen to Bert and Ernie so you won't miss a call eventually directed to you.

Photo A. The author modified the Motron Auto Kall AK-4 to solve two common problems.

A Logical Solution

A Touch-Tone decoder alone, connected to a scanner, will solve the second problem: you won't have to listen to all the traffic until you're called. But it won't solve the first problem of the scanner getting hung up on a busy channel. Combining the logic of the decoder and the scanner will, however, solve both problems.

What happens when a normal scanner switches to a busy frequency? The squelch circuit detects a carrier and outputs a logic control signal that tells the scanner to stop scanning. To operate as a Touch-Tone activated scanner, I've opened the logic control line coming from the squelch circuit and inserted a logic signal from the first decoded digit of an Auto-Kall AK-4 Touch-Tone decoder. The scanner won't stop unless it receives the first digit of your code.

If the scanner is programmed to scan 10 frequencies, and it's scanning at the rate of 10 channels per second, the calling station must hold down the first digit of the code for at least one second. This gives the scanner enough time to make one complete cycle through all the frequencies. Once the first digit is decoded, a timer is set that stops the scanner for about 10 seconds, allowing time for the decoder to receive the rest of the code. If the right code sequence is not received within 10 seconds, the scanner resumes scanning. If the correct code is received, another timer is triggered that both turns on your speaker and keeps the scanner tuned to the calling frequency. The calling station identifies and tells you which frequency he's calling on.

I've been using this system for several years now, and it's been a real life-saver. We have four speakers connected to the scanner/decoder and placed at strategic places throughout the house and shop. My wife can always get through on simplex when she's doing errands around town. Friends from various parts of the state can use different repeaters to reach me. Early one Sunday morning, when the phone had been accidentally left off the hook, my brother-in-law was able to wake us up by calling on 2 meters; there had been a serious family medical emergency.

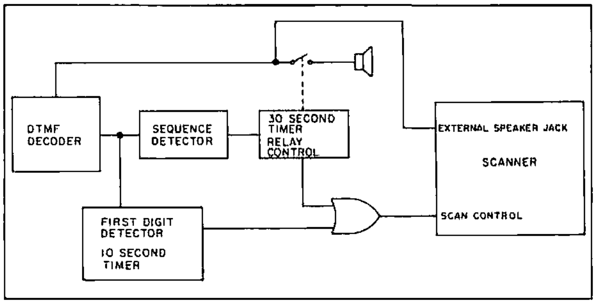

Figure 1. System block diagram.

Scanner Modifications

I implemented this scanning system using the Radio Shack PRO-57 scanner and the MoTron Auto Kall AK-4C DTMF decoder. You can use almost any scanner and DTMF decoder for this project. The PRO-57 is currently Radio Shack's least expensive scanner. Most scanners use similar receiver and scanning circuits. The PRO-57 uses the MC-3361 FM receiver IC. Pin 13 is the scan control output. When it's low, the scan function is enabled. When a signal is present, it goes high and scanning stops.

If you use a different scanner, check the schematic for the line that goes from the receive IC to the scanning section. If you check this line with a logic probe, you should see it changing states when you turn the squelch control on and off. Normally, when the receiver is unsquelched, it tells the scanning control to stop scanning. Since the scanner needs to be stopped with a DTMF signal instead of a carrier, this control line is broken and the input to the scan control is diverted to the output of the DTMF decoder. The line is broken after it goes to the mute circuit on the power amplifier.

Adding Scan-Control and External Speaker Jacks

Two mini-phono jacks (3.5mm) were added to the scanner. One is used to connect the first digit detect circuit in the DTMF decoder to the scan control in the scanner. The

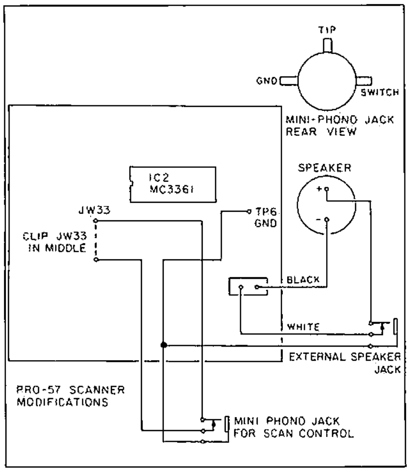

Figure 2. PRO-57 scanner modifications.

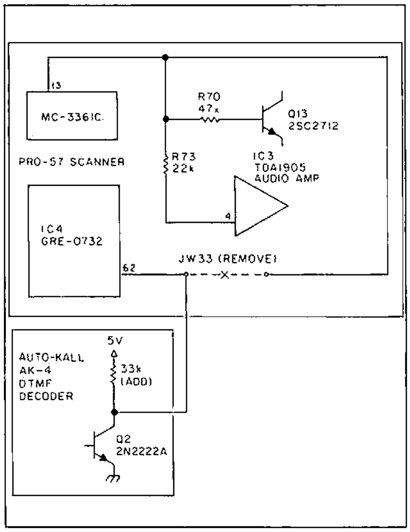

Figure 3. Scan control modifications combine the logic of both the decoder and the scanner.

other is used to add an external speaker jack to the scanner. This provides a way to feed audio to the decoder and to control the speaker line with the decoder. To add the mini-phono jacks, drill two ¼" holes on the side of the chassis, just below the speaker.

Wiring the Scan Control Jack

You don't have to remove the PRO-57's circuit boards. You do have to use anti-static precautions. Be sure to discharge any static electricity on your body by touching a ground before working on the circuit board.

There is a short jumper wire about ½" long in the center of the main board, labeled JW33. One side of JW33 goes to the squelch control, pin 13 of IC2, R73 and R70 (surface mounted on bottom of board). The other side of JW33 goes to IC4 pin 62. Clip this jumper in the middle and raise each side off the board.

Solder wires about 5" long to each side of the cut jumper. Solder the wire that goes to IC4 (the side closest of C110) to the "tip" connection on the scan control mini-phono jack. Solder the other wire (nearest D14) to the switch section of the jack. Connecting the scan control through the switch section will cause the scanner to operate normally when the decoder is unplugged. Connect a wire from the ground lugs of both the scan control and speakers jacks to TP6, the PCB ground.

Wiring the External Speaker Jack

Unsolder the white wire going to the speaker's positive side. Wire this to the "tip" lug on the external speaker jack. Wire the switch lug to the positive lug of the speaker with a short piece of wire.

Decoder Modification

The Auto-Kall AK-4 is well-suited for this project because it has two independent timers. You need one timer to stop the scanner for a short time, 5-10 seconds, upon receipt of the first digit. You need a second timer to turn on the speaker relay for about 30 seconds. You can adjust both times with on-board trim pots. The output of each timer is fed into a NOR gate which is again inverted by an open collector transistor (with a pull-up resistor added). This output is then connected to the scan control. When either timer is triggered, the NOR gate will output a logic-low that turns off the transistor. This puts a logic-high on the scan control line and causes the scanner to stop.

The first timer is used to stop the scanner for 5-10 seconds if the first digit of the sequential DTMF code is received. This stops the scanner to allow enough time for the rest of the code to be entered. If the rest of the digits aren't received, it goes back into scan mode on timeout. If the rest of the code is received, the second timer is triggered, activating the on-board relay and turning on the speaker. This timer is adjustable from about 10 to 60 seconds. A red "call" LED is also latched on, to indicate a received call.

The short timer was originally part of a "group-call" circuit. When triggered, an output would set a NOR gate latch. The timer in this circuit is modified to give an output for 5 to 10 seconds by changing C7 to 10 µF. One of the NOR gates in the latch is isolated and used to control the open collector transistor "GC" output for the scan control.

Modification Details

Remove the following parts on the decoder (AK-4) board: R4, 1k; R18, 33k; R32, 1k; C6, 1 µF; C8, 0.1 µF; and C7, 3.3 µF. Replace C8 with a jumper wire. Change C7 to 10 µF. Remove U2 from its socket, bend out pin 4 and place it back in the socket so that it's disconnected. Remove CR12.

Solder a wire from U4, pin 4, to U2, pin 1. A trace coming from pin 4 of U4 goes to a feed-through hole. Use this hole for one end of the wire by scrapping off the solder mask. Solder the other end of the wire to the hole vacated by R18 that went to pin 1 of U2. A second wire goes from the hole of C6 (that went to U6, pin 11) to the hole formerly used by R4 (that connected to U2, pin 2). Solder a 33k ¼-watt resistor (you can use R18, which was removed) from the GC output (next to +IN) to the pad marked +5.

Three jumpers on the board are used to configure the board for various functions. Connect only jumper J3; leave the other two blank.

Program the board as per manufacturer's instructions. Solder a diode from the first digit of your code, in the programming matrix, to the GC PAD. Cathode side goes to GC PAD. This will cause the short timer to be triggered when the first digit is received.

Connect the GC output of the AK-4 decoder board to the mini-phono jack scan-control input. Connect an audio cord from the external speaker jack of the scanner to the audio input of the decoder.

Testing

Start scanning several frequencies. Using a simplex frequency, hold down the first digit

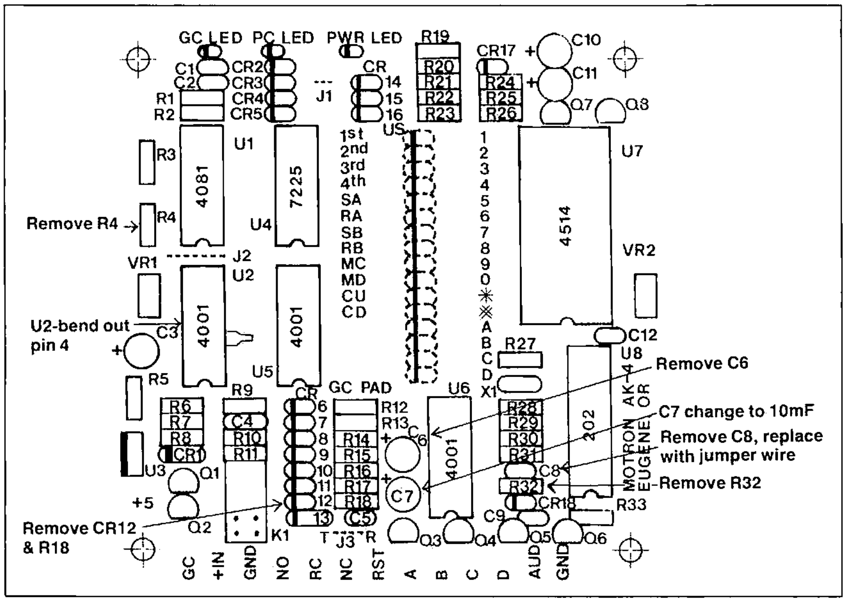

Figure 4. AK-4 modifications (circuit board details).

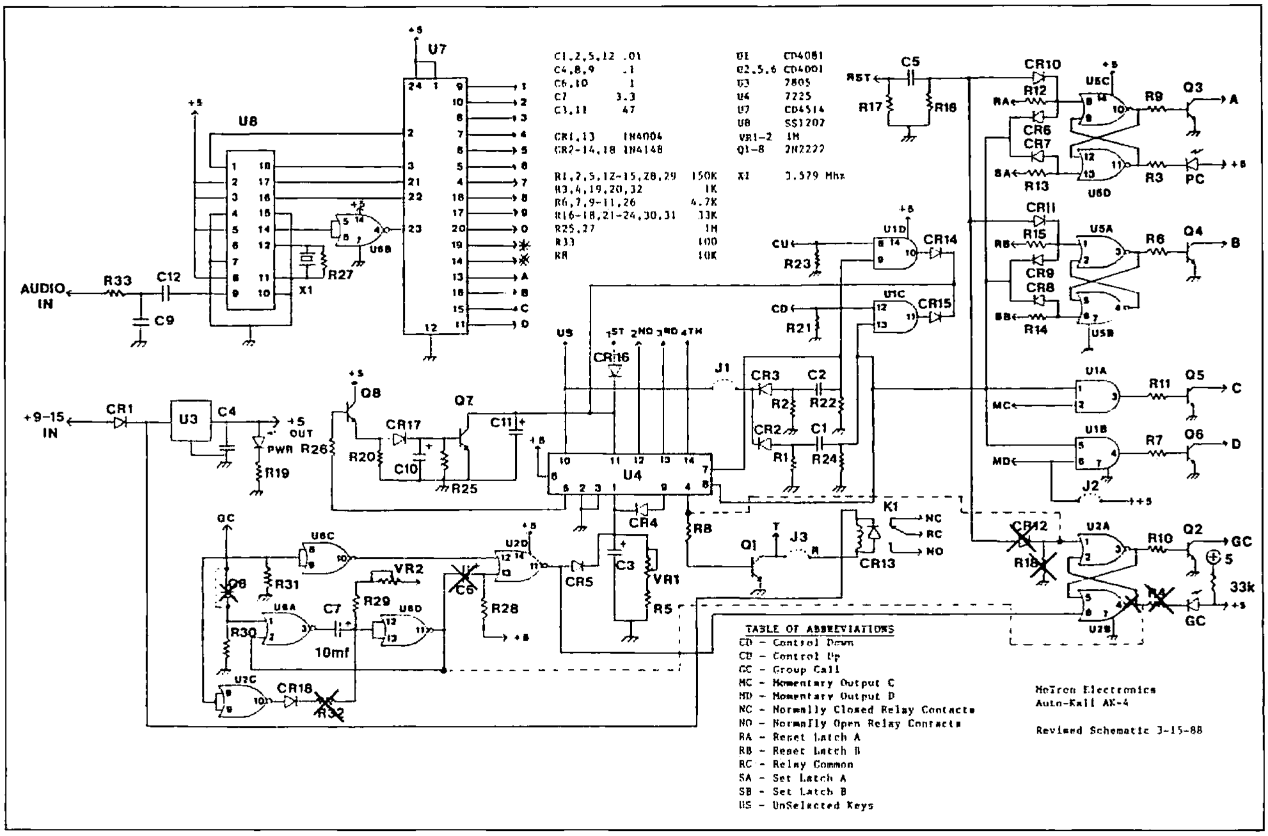

Figure 5. Modified AK-4 schematic diagram.

of your code. When the scanner gets to that frequency, the GC output should go high and cause the scanner to stop scanning. Enter the rest of your code. If all is working well, the relay in the decoder should turn on to open up your speaker or activate an alarm.

The SSI-202 decoder chip used on the AK-4 decodes DTMF signals in about 40 ms. Occasionally, if you start to enter the first digit of your code just as the scanner is crossing the calling frequency, the control signal stops the scanner too late, on the following channel. During testing, this happened only about once every fifty times.

This system will give you a powerful communications tool for either routine or emergency traffic. It will make it possible for you to be reached at any time over a wide geographic area, through the best possible path.

Although you may use other scanners and decoders, you can obtain the AK-4 or AK-4C (complete in a box with a speaker) from MoTron Electronics, 310 Garfield St., Suite 4, Eugene OR 97402. Tel. (503) 687-2118; order line, (800) 338-9058. For $10, MoTron will do the scan modifications on the AK-4W or AK-4C. ■

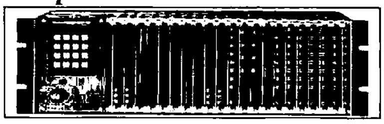
Repeater - Link Controller



RBC-700 Controller

The RBC-700 represents the latest generation of advanced repeater controllers. These series of controllers can connect up to 7 independent receivers and transmitters. 24 different configurations are available that supports up to 5 fully duplexed link radios, 4 independent remote base radios, and multiple repeaters simultaneously. Card-cage design allows expansion by simply adding cards and firmware. A true 7 position cross-point switch is utilized that allows each receiver / transmitter to independently connect to other Rx/Tx combinations as desired. Multiple independent Rx/Tx paths are supported.

Multiple Repeater control
Up to 5 Duplexed Links
Up to 4 different Remotes

73 Review

by Joe Holman KA7LDN

The ICOM IC-970H VHF/UHF Multiband All-Mode Transceiver

A great rig for both satellite and local communications.

ICOM America
2380 116th Avenue NE
Bellevue WA 98004
(206) 454-8155
Price Class: $3000

Recently I had the opportunity to use an ICOM IC-970H VHF/UHF (i.e., 2m and 70cm) multiband transceiver. This is a full-featured multi-mode rig designed with the satellite operator in mind. It's also a fine rig for terrestrial contacts both on SSB/CW and FM.

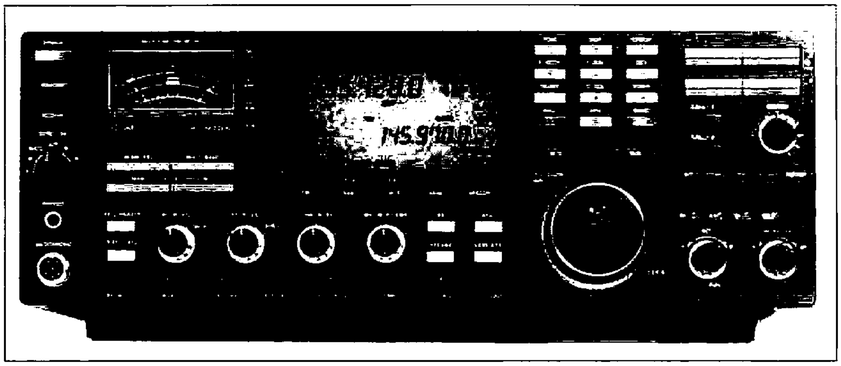

Photo. The ICOM-970 multiband VHF/UHF transceiver.

Dimensions and Front Panel Layout

The IC-970H is a big radio: 16.7" W x 5.9" H x 16.0" D, approximately the same size as ICOM's IC-765 HF radio.

The front panel of the radio supports "bigger-the-better" controls. The tuning knob is 2" in diameter, and the basic control knobs are 0.75" in diameter. In the center of the front panel, there is a 4.5" x 2.5" black-on-yellow LCD display which provides the following information:

- Main and sub mode of operation.
- Main and sub operating frequencies.
- General coverage RX on/off.
- RIT change of frequency (only for main).
- Main and sub VFO (A or B) selection.
- Main and sub memory channels.
- Sub receiver S-meter.
- Tuning pitch indicators.
- Main and sub duplex indicator.
- Scan indicator.
- Tone/squelch/beep indicator.
- Split operation indicator.

Also, the radio has a large S meter, 2.75" x 1.75", that is placed directly to the left of the LCD display.

On the very left side of the radio, you can find the SATELLITE switch which provides the following six tracking configurations (and which proved to be very useful during my satellite experimentation and operation with the radio):

- OFF—Main and sub frequencies do not track.
- N (Normal)—Main and sub frequencies change in same direction.
- R (Reverse)—Main and sub frequencies change in opposite direction.
- SATL—Used for programming uplink and downlink pairs to memory, no tracking takes place.
- SATL-N—Allows selection of uplink/downlink memory channel, tracks in same direction.
- SATL-R—Allows selection of uplink/downlink memory channel, tracks in opposite direction.

I'll discuss more about the SATELLITE switch in the "Satellite Memories" section.

Manual

The manual is 48 pages long. The majority of the manual describes what each of the control functions and connections on the front and rear panels do. The remaining sections of the manual provide general operating procedures for packet and satellite operation, and provide details (with many internal views of the radio and replaceable components) about how to install optional accessories and modify factory set internal controls. I was impressed with the level of detail presented in this manual. It is one of the best that I have seen ICOM produce. See Table 1 for a complete listing of the IC-970H's specifications.

Receiving and Transmitting

During my voice communications, I spent most of my time operating on AO-13. I made QSOs on this satellite for just about three-fourths of the entire pass on two different days. This allowed me to test the IC-970H during various operating conditions, such as when the squint angle of the satellite's antenna was greater than 20 degrees, less than 20 degrees, and on the two major modes used: Mode B (70cm up and 2m down) and Mode J (2m up and 70cm down).

For antennas, I used the KLM 18C (12.0 dBi gain) for 70cm, and an old beat-up Cushcraft 10-element beam (10.5 dBi gain) on 2m. The preamplifiers were the ICOM AG-35 (15 dB gain, NA noise) for 70cm, and the ICOM AG-25 (15 dB gain, NA noise) for 2m, mounted at the antenna feedpoint. For feedline, I used an 80-foot run of Belden 9913 (2.6 dB loss per 100 feet) for 70cm, and a 50-foot run of RG-8/U foam (2.0 dB loss per 100 feet) for 2 meters.

Most of my AO-13 QSOs were made on Modes B and J. While operating on AO-13, I worked the following stations (all contacts were on Mode B, unless otherwise noted): AA6PJ, KC7IT, DD5LQ, ON1LST, PE1HXD, FC1GNV, PA0STE, OE5WHN, SM2SWU, JA9WMS, UA0OB (both B and J), JR2UOE, and VK4KZR (Mode J only). As you can see, I made contacts with many locations around the world.

In addition, I used my IC-275H and IC-475H during these passes to compare the versatility of the IC-970H's uplink and downlink systems.

The first thing that caught my attention was the IC-970H's audio. Its audio is much more robust (better bass) than what my IC-275H or IC-475H produces. Good audio always makes satellite communications more enjoyable.

For receiving, the IC-970H has comparable sensitivity to both the IC-275H and the

IC-475H. Most stations running about 25 watts and up on AO-13's 70cm uplink (for Mode B) were S-5 and above on the IC-970H's 2m downlink receiver. Similarly, stations using 2m on the uplink (for Mode J) and running about 25 watts or more, resulted in downlink signals in the range of S-4 to S-5. Stations using near 75 watts and up were producing S-9+ signals. Please note that your signals may vary due to the gain of your antennas and loss in your transmission line, and the current squint angle of the satellite's antennas. In general, though, the results were very much on a par with other satellite receiver systems that I have used in the past.

For transmitting, the 30 and 35 watts produced by the IC-970's 70cm and 2m transmitters resulted in below average signal levels when compared to many of the other downlink signals on the satellite. To increase my signal, I decided to activate the speech compressor. The speech compressor produced a very noticeable increase in signal strength and improved the basic sound quality. I estimate the gain increase was almost 6 dB (one ICOM S-unit).

1200 MHz Option

The IC-970H comes with 2m and 70cm band units installed from the factory. These two bands are primarily used for Mode B and J satellite communications. In case you want to operate on Mode L (1296 MHz uplink and 70cm downlink), the IC-970H lets you install the UX-97 1200 MHz optional band unit for Mode L use. The UX-97 supports SSB, plus CW and FM, and has 10 watts output power.

Satellite Tracking and Memories

In addition to allowing you to store 99 different frequencies into the per band memory channels, the IC-970H allows you to store 10 uplink/downlink frequencies and mode pairs (transponder uplink and downlink tracking frequencies). I found this feature to be very convenient. I programmed frequencies for AO-13's Mode B into channel 1, AO-13's Mode J into channel 2, and FO-20's Mode J frequencies into channel 3. (To program into a particular channel, the SATELLITE switch must be in the SATL position.) Now when I need to use a particular mode on one of these satellites, I put the SATELLITE switch to the SATL position, enabling the 10 special memory channels; then I select a particular channel with the Memory Channel Switch, and turn the Satellite Switch to the corresponding tracking direction (either N or R position). Tuning with the main dial now changes the main and sub frequencies in either the same direction or inverse direction, accordingly.

How did I compensate for the Doppler shift? When operating in this manner and encountering Doppler shift, just deactivate the MAIN/SUB switch, allowing frequency changes on both the main and sub VFOs at the same time. Change the RX frequency just enough to allow for the Doppler shift. After this tuning, activating the MAIN/SUB switch allows you to continue to change frequencies on both the main and sub VFOs at the same time by using the main dial.

Tracking in this manner, but not using a particular stored memory channel, is also available with the two remaining positions of the SATELLITE switch.

Scanning

The main and sub scanning features are not necessarily needed for satellite operations, but they are good for local activity. The feature I liked best is that both the main and sub bands can be selected for scanning at the same time (by using the Main and Sub Scan Switches) in addition to the more common individual band scan feature found on most receivers.

Both the main and subbands can have 99 memory channels programmed, and they each have the capability to have a selected portion of their bandwidth scanned (this feature uses the P1 and P2 memory channels). The IC-970H can perform four types of scanning: *programmed scan*, which scans between two programmed scan edges; *memory scan*, which repeatedly scans all memory channels in the selected band; *mode-select memory scan*, which repeatedly scans memory channels with the same selected operating mode in a particular band; and *multiband memory scan*, which allows scanning with an optional installed band.

Satellite Packet Operation

In addition to using the IC-970H for voice communications, I used the radio to copy telemetry from FO-20, DOVE, and Pacsat. Currently, I am using a PAC-COMM Tiny-2 and PSK-1 to decode the BPSK and AFSK telemetry signals from these birds with my IC-275H and IC-475H radios. To copy the telemetry using the IC-970H, I just inserted a microphone connector and connected the audio input and ground of the PSK-1 or Tiny-2 (depending upon which bird I was copying from) to the microphone connector. This provided the bare minimum connections required to perform telemetry reception. For DOVE (AFSK FM), I just tuned to 145.825 and let the bird pass over. (Here, I did not need to tune for Doppler.)

However, for the FO-20 and Pacsat satellites (BPSK SSB), I needed to manually tune for the correct Doppler-shifted signal. This

Specifications

Frequency coverage	140.1–150.0 MHz	
	430.0–450.0 MHz	
	1200 MHz Band (with optional UX-97 unit)	
	50–900 MHz (with optional UX-R96 unit, RX only)	
Tuning step increment	SSB, CW	10 Hz
	FM	5, 10, 12.5, 20, 25, or 100 kHz
	All modes	1 kHz and 1 MHz
Operation modes	SSB (A3J), FM (F3), and CW (A1)	
Power requirements	13.8 VDC ±15%	
Antenna impedance	50Ω unbalanced	
Current drain (2m)	16A on transmit	
	2.5A on receive	
Usable temperature	−10 degrees C to 60 degrees C	
Frequency stability	±3 ppm	
Dimensions	425 W x 149 H x 406 D mm	
Weight	15.0 kg (without internal power supply)	
	17.3 kg (with power supply)	
Output power	5–35W (2m SSB and CW)	
	6–45W (2m FM)	
	5–30W (70cm SSB and CW)	
	6–40W (70cm FM)	
	≤10W (23cm SSB, CW, and FM)	
Modulation system	SSB balanced modulation	
	FM variable reactance frequency modulation	
Spurious emissions	more than 60 dB below peak output power	
Carrier suppression	more than 40 dB below peak output power	
Unwanted sideband	more than 40 dB below peak output power	
Microphone impedance	600Ω	
Sensitivity	SSB and CW	<0.11 µV for 10 dB S/N
	FM	<0.18 µV for 12 dB SINAD
Squelch sensitivity	SSB and CW	<0.56 µV
	FM	<0.18 µV
Selectivity	SSB and CW	>2.3 kHz for −6 dB
		<4.2 kHz for −60 dB
	CW narrow	>500 Hz for −6 dB
		<1.3 kHz for −60 dB
	FM	>15 kHz for −6 dB
		<30 kHz for −60 dB
Audio output power	1.5W with an 8Ω load at 10% distortion	
RIT variable range	±9.99 kHz	
Notch filter range	> ± 1.2 kHz	
Notch filter attenuation	>25 dB	

Table 1. The IC-970H's specifications.

tuning is common, and can be eliminated by connecting additional lines from the PSK-1 to the ACC plug on the rear panel of the IC-970H.

The telemetry sent from FO-20, DOVE, and Pacsat did not require the use of a preamp to receive good packets. All passes I experimented with had elevations of about 25 degrees or higher, and telemetry could be decoded for about three-fourths of the entire pass. Signals were on the average of S-5, with peaks in the range of S-9 to S-20 on FO-20 and Pacsat (SSB), and full S9+40 on DOVE (FM). During these experiments, my antennas were placed to point directly west and at 0 degrees elevation. Obviously, you can get better signals if you point your antennas directly at the satellite.

CT-16 Interfacing

On the rear panel of the IC-970H, a TTL-level remote jack is provided for CI-V converters. This remote jack can also be used to track uplink and downlink frequencies with another radio, such as the IC-1271 or IC-1275 (if you already have one and don't need to buy the optional 1296 MHz module), in conjunction with ICOM's CT-16 satellite interface. This will operate in the manner described above when you are tracking uplink and downlink frequencies in the same or reverse directions.

Pros and Cons

Features I'd like to see:
- •SWR meter.
- •DTMF keypad.
- •A microphone included with rig.
- •Increased output power comparable with other H models.
- •Individually activated preamps.

Features I liked:
- •Automatic tracking for uplink and downlinks.
- •Separate memory channels for satellites.
- •Excellent weak-signal receivers.
- •Great audio quality.
- •Large frequency display.
- •Large multi-function meter.
- •Additional S-meter for sub band.
- •Large easy-to-handle controls and switches.
- •Additional band units can be installed.

It's Worth Buying

Overall, the IC-970H is a great rig for satellite communications and local activity. I found the IC-970H easy to use, and very capable of either voice or data satellite communication modes. 73

1691 MHz Weather Satellite System

Spectrum International, Inc. is pleased to announce their appointment as North American and International distributor of **Time-Step Electronic's Weather Satellite Receiving System.**

This high quality, low cost system consists of:

1691 MHz GaAs FET Pre-ampl.	model TS-1691-P.Amp	$ 175
1691 MHz Receiver	model TS-1691-Recvr	$ 450
Decoder Board & Software	model TS-VGA-SAT3	$ 300

Also available to complete the system are:

Low Loss (microwave) Coaxial Cable (65ft) with connectors.	model 1691-coax ass'y	$ 45
1691 MHz Loop-Yagi Antenna	model 1691-LY(N)	$ 92
1691 MHz Loop-Yagi Extension	model 1691-LY-XTN	$ 75

PC-SAT System (all the above items) **$1100**

Demonstration Disc (IBM-PC VGA compatible) of signals recorded from PC-SAT system. $ 5

by Dick Goodman WA3USG

Skymoon

Software for EME communications.

Skymoon
9102 Kings Drive
Manvel TX 77578
(713) 331-4200
Price Class: Version 1, $40; Revision 2, $50

One evening in late November 1990, I received a telephone call from Bill Brown WB8ELK informing me that Dave Blaschke W5UN was on the air operating moonbounce. Bill suggested that I try receiving W5UN on 2 meters. I was quite pessimistic about my chances because my antenna system consists of a single Hy-Gain circularly-polarized yagi used for OSCAR satellite operations. I do, however, have a low-noise mast-mounted preamp and a short (60 foot) run of RG-213 coax going to the shack, so I gave it a try.

It took about 10 minutes, but from under all the noise I was finally able (barely) to make out the W5UN's callsign on CW. It was about the weakest signal that I have ever heard, but considering that I was using a single yagi it was quite an accomplishment. I have read articles in several amateur journals stating that the big guns on moonbounce could be received on modest equipment, but I never believed it, until now!

While the "Instant Track" program gave me the azimuth and elevation of the moon, and allowed me to automatically point my antenna, I found there were quite a few other considerations not addressed by this software package for moonbounce operations.

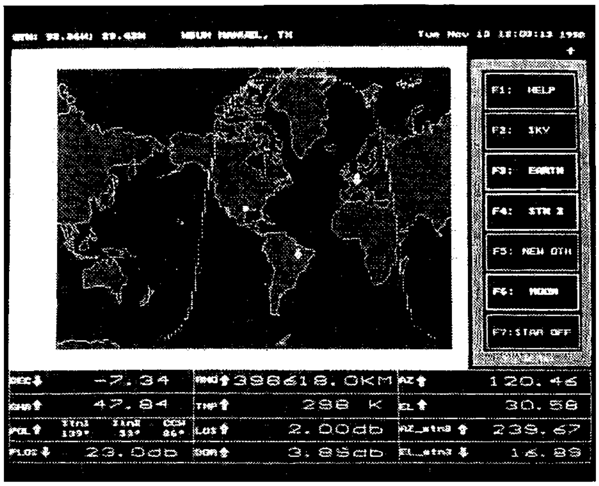

Photo A. Main screen of SKYMOON.

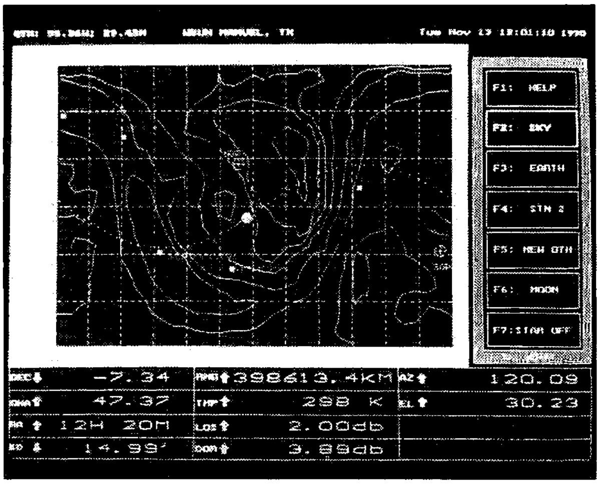

Photo B. Map showing the moon's location in relation to noise sources in the sky, as viewed from your QTH.

Enter: Skymoon

Computer software has certainly evolved in the last 10 years, especially in the field of amateur radio. Since the software developers who write ham radio applications software are usually hams themselves, they are generally technically-oriented individuals. This translates into a useful software package for others with similar interests. Look at the impact of "Packet Cluster," and the variations of logging programs on chasing DX. There are also many effective propagation forecasting programs for determining when DX will be available. For the ham interested in OSCAR operations, there are several good satellite tracking programs which will indicate when the desired satellite will be in view. Now, for the ham interested in moonbounce, or EME (Earth-Moon-Earth) communications, there is a spiffy new software package called "Skymoon," written by Dave Blaschke W5UN, of international moonbounce fame!

I reviewed Skymoon on two different computers: a Beltron AT clone running at 12 MHz with a VGA display, and a Comp-U-Add 386 running at 16 MHz using an EGA, and later a VGA, display.

There are two revisions of Skymoon. Revision 1.0 will run on any IBM PC clone with Hercules, CGA (Mode 4), or a CGA monitor. Version 1.0 comes on a single 5.25" floppy disk, and it can be executed and run from a single drive system. Revision 2.0 comes on two 5.25" floppy disks, and requires either a hard drive or a larger capacity floppy drive (720K, 1.2M, or 1.44M). Skymoon requires 256K of memory to run. For this article, I primarily reviewed Revision 2.0, but I'll provide a brief comparison to Version 1.0 later in the review.

Skymoon is easy to install—you simply copy all the files from the two floppy disks to their own directory on your hard drive. Before you run Skymoon, you must execute a configuration program. This tells Skymoon your offset to UTC, call, QTH, and latitude and longitude.

To start Skymoon, type "SKYMOON" and press <ENTER>. It takes Skymoon about 10 seconds to draw its graphical interface screen. This generates a world map showing the location of the moon and a moon rise/set line (see Photo A). To the right of the map is a menu which describes the purpose of each function key. Below the map are multiple windows of real-time data containing the following information:

- The primary station (your station) azimuth and elevation to the moon (if the moon is not in view, the elevation will be a negative number).
- The current distance to the moon in kilometers.
- The background sky temperature in degrees Kelvin. Depending on where the moon is in relation to noise sources in the sky, this value will change.
- Path loss in dB relative to when the moon is closest.
- Total path degradation in dB.
- The moon declination angle and the Greenwich hour angle (GHA).
- For those used to astronomical positioning parameters, the moon right ascension and the semi-diameter.

Next to each parameter is an arrow that gives the status of each (increasing or de-

creasing). Also, at the top left of the screen are your latitude, longitude, and location name. At the top right is a real-time clock-calendar. Using single keystrokes, this clock-calendar may be stopped, changed in time or date, and restarted. All parameters for the moon at this new time will then be displayed (this does NOT affect your DOS clock). Also included with the clock function is an "East-West Sequencer" which will, if activated, generate a "beep" every two minutes, and display either "East" or "West" on the top of the screen next to the clock. This function is used to determine when to listen or transmit when calling CQ. In Revisions 2.0 and above, pressing the "up-arrow" will generate a listing of the moon's rise and set times for the primary QTH.

The Function Keys

The menu of function keys is quite helpful. Pressing F1 will generate a help screen almost anywhere in Skymoon. F2 will present a map of the sky in place of the Earth (see Photo B). This map is formatted with contour lines of sky noise, with the moon and the path that the moon will take, superimposed over it. Changing the date (or time) will move the position of the moon to its appropriate place on the skymap. F3 will regenerate the map of the Earth.

Function key 4 (F4) is the most versatile function of Skymoon. It allows a second station to be displayed on the real-time map of the Earth, with the following parameters displayed on the bottom of the screen:

- Primary station's (your station) spacial antenna polarity.
- Second station's spacial antenna polarity.
- Antenna polarization correction angle (difference between the above two polarities).
- Antenna polarization mismatch loss in dB.

The second station may be selected by one of three methods. The first is to use the cursor positioning keys to move the "second station indicator" to the desired point on the world map. If you press <ENTER>, this point will be marked with an arrow and all applicable data will be displayed, including grid square, distance, and direct antenna heading. The second method is by direct entry of latitude and longitude. The third method is by direct entry of the grid square. Revisions 2.0 and above let you choose one of the many stations included in the EME station directory (included in this program) as the second station. This directory includes almost all known EME stations in the world, and may be accessed by callsign. Revision 2.0 also lets you compute the moon rise and set times for the second station. *[Ed. Note: Revision 2.1 is now available. Some of the new features are: rapid appearance of the Sky Map and World Map, Az/El direction to ANY point in the sky, single keystroke time changes, metric distance option (km).]*

Function key 5 (F5) will bring up a QTH menu that offers several pre-programmed locations. Choosing one of these will replace your QTH with the one selected (your QTH will be added to the QTH menu, so quick recovery is possible). The world map and related data will now be displayed for the new QTH. Revisions 2.0 and above allow access to the EME directory, and replacement of the primary QTH with any station listed.

Function key 6 (F6) toggles the moon rise-set line on or off. This would be beneficial if you are using the sun grayline function for DXing (see F7 functions).

Function key 7 (F7) is multi-functional. Press it once when the world map is on the screen and the sun symbol and grayline will appear. The azimuth and elevation to the sun will appear in the data windows below. Toggling it several times will profile high and low noise areas of the sky.

This software package also has several features that I did not try. One is the capability to add additional entries to the EME directory.

Version 1.0 of this program (for CGA and EGA) runs noticeably slower. It also doesn't contain the directory of EME stations, and does not have the moon rise-set prediction function.

All things considered, this is a well-written software package that should appeal to anyone who wants to consider EME operations. All screens are logically structured and present the data in an easy-to-read manner. The operating manual is complete and provides a tutorial that will have anyone mastering this program in less then an hour.

TE SYSTEMS new **HPA Series** of high power amplifiers now available through select national distributors.

All amplifiers are linear (all-mode), automatic T/R switching, and incorporate optional GaAs FET preamp. Amps are usable with a wide input drive level range. Thermal shutdown protection and remote control capability included. All units are designed to ICAS ratings and meet FCC part 97 regulations. Approx. size is 2.8 × 10 × 11.5" and weight is 8 lbs.

Consult your local dealer or send directly for further product information.

Models also available without GaAs FET preamp (delete G suffix on model #). All units cover full amateur band – specify 10 MHz bandwidth for 420-450 MHz amplifier. Continuous duty repeater amps also available.

Amplifier capabilities: 100-200 MHz, 225-400 MHz, 1-2 GHz, Military (28V), Commercial, etc. also available – consult factory.

Two Meter EME Primer

Your guide to moonbounce action!

by Dave Blaschke W5UN

Are you interested in EME (Earth-Moon-Earth) operation, but you don't know how to get started? In this article, you'll find out how to determine if your current station is capable of making EME contacts, and if not, what improvements you'll need to make if you want to hear and work EME stations. You'll also learn basic operating information and procedures. You may be surprised to find that if you're willing to spend a little effort, and believe you can do it, it's not impossible to get involved in this exciting area of amateur radio!

EME communications experiments were first conducted by amateur radio operators in the late 1940s. It remained a curiosity and experimenter's mode for many years because most 2 meter stations had poor antennas and noisy receiver front ends. All of that has changed in recent years. Now, almost anyone capable of putting together a reasonably sized station on 2 meter CW can share in this exciting and challenging form of communications.

Photo B. The W5UN EME array is rotated via 2 truck chassis (powered via an electric motor on the driveshaft of one of the vehicles) which literally drive the antenna around a large circular roadbed. The array pivots around a rotating pole in the center. An electric winch along with a series of pulley and cables provide elevation control.

You May Be Set Up Now

In fact, I have discovered that there are many amateur stations currently active on 2 meter CW that are capable of making EME contacts, but they haven't tried it because they don't know they can do it. I've spoken with some who are hard pressed to believe that they are capable of performing such a seemingly impossible feat. But I can assure you that anyone who has more than 100 or 200 watts of power, and an antenna with 16 or more elements, can expect to make a few EME QSOs on moonrise or set, without further station improvements.

Photo A. The new W5UN EME antenna array providing 30.75 dBd of gain (the old array was destroyed by a tornado last March). Dubbed the "Mighty Big Array" or MBA, it consists of a total of 48 stacked long boom yagis (modified M² model 2M5WL).

For the smaller stations who can only run 100 watts or so of output power, a good antenna, which can now be easily built or inexpensively bought, is probably the only other thing needed to accomplish half a dozen EME QSOs. Nowadays, the only amateurs with no chance to participate in EME work are those who run FM only, have only vertical antennas, or use only HTs.

Several hundred amateurs worldwide, many in Europe, are currently active and regular on 2 meter EME. New stations are appearing almost daily. Stations with large antennas and high power, such as my own

100 Countries worked via 2 meter EME!

Photo C. Dave Blaschke W5UN at the control of his moonbounce station after working VS6BI and J79/W6JKV for countries 100 and 101 on October 28, 1990. It took him eight years to reach the century mark (his first EME contact was with K1WHS in 1981). He's currently up to 105 countries worked after contacting CE0ZZZ, 9M8SEA, 7P8EN (Lesotho) and ZS9Z (Walvis Bay). [Ed. Note: Looks like EME could be a great way to avoid those pile-ups to work those rare ones!]

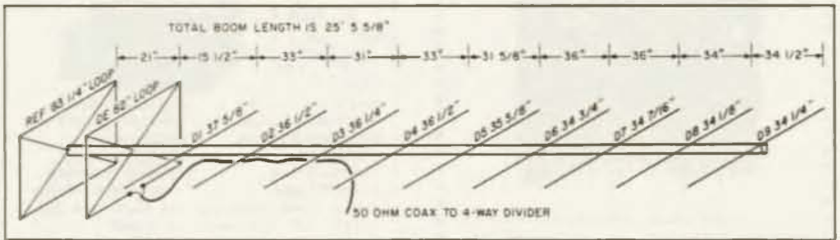

Figure 1. Modified W5UN quagi (optimzed for 144.050 MHz - gain of 13.25 dBd). All directors are ⅛" solid aluminum rod cut to within ±1.16". Reflector and driven elements are shaped into square loops using number 12 solid copper wire with TW type insulation. Leave the insulation in place. Boom is either non-conductive sealed wood or Fiberglas™.

station, W5UN, make it possible for small stations to make EME QSOs today (see Photos A and B).

After *QST* published the article about W5UN's Texas MBA (Mighty Big Antenna) in the January 1989 issue, I was deluged with requests for information and schedules by amateurs who knew nothing about EME communications. Most who wrote or called me had never listened for return echoes before. EME communications requires more structured operating procedure and equipment specifications. For example, antennas must be reasonably sized, and receiving systems must have fairly quiet, sensitive front ends.

Antennas

The first, and most important, piece of equipment needed for EME work is an adequate EME antenna system. Such a system is defined here as one having sufficient elements, properly spaced and phased to yield the gain required for successful EME communications. (Path-loss formulas can give you an idea of the power and antenna gain required.) To communicate by moonbounce, you must be heard by, as well as be able to hear, other moon-reflected signals. It is not known precisely what the minimum gain of an antenna needs to be, but based on a lot of operating experience, I have found that the minimum gain stations need in order to be heard by my station reliably, is around 13 true dB referenced to a dipole when transmitter power into that antenna is no less than 100 watts.

Table. Example of a scheduled EME contact between W4ZD in Florida (western station) and ZD8MB on Ascension Island (eastern station).

Such antenna and power will permit W5UN to hear you during most of the schedules you're likely to run. A random QSO with W5UN is even possible if a small station calls until heard (this might take weeks or months, but it *is* possible).

"What kind of antenna do I need for an EME station?" is an often-asked question. EME stations use many different types, but the long boom yagi is the most popular. By long boom, I mean boom lengths greater than four wavelengths (about 27 feet). Several of this type are sold commercially. A few which come to mind are the KLM17LBX, Cushcraft 32-19, 42-18XL, Cu-dee, F9FT, and the M² 2M5WL.

For those who find commercial antennas a bit too much for the budget, an inexpensive long boom quagi, with the necessary gain for EME listening and a few QSOs, can be home-brewed (see Figure 1).

Due to computer modeling, advances in design have changed older home-brew antenna dimensions, resulting in better performance. So, if you are contemplating building your own EME antenna, please keep this in mind, and make sure the design you are going to build has been properly modeled and range-tested to ensure optimum performance.

It is possible for stations using OSCAR satellite antennas to hear EME signals from the very large stations. Stations using these antennas have been challenging for W5UN to hear. However, it can be done if such stations will make EME schedules in advance. Recent OSCAR antenna stations worked on schedule by W5UN were CE0ZZZ (KLM22C and 170 watts), KB6BA (KLM22C and 300 watts), and 9M8SEA (unknown OSCAR antenna and 300 watts). The problem with most satellite antennas is that they have circular polarization. This reduces the signal by 3 dB for EME stations, who nearly always use linearly polarized antennas.

The key to all of this is that whatever type of antenna you choose, it must work at its peak capability. Feedline losses, misphasing, and other problems will reduce its effectiveness.

Power

High power is preferred because most stations cannot put up large-sized arrays to make

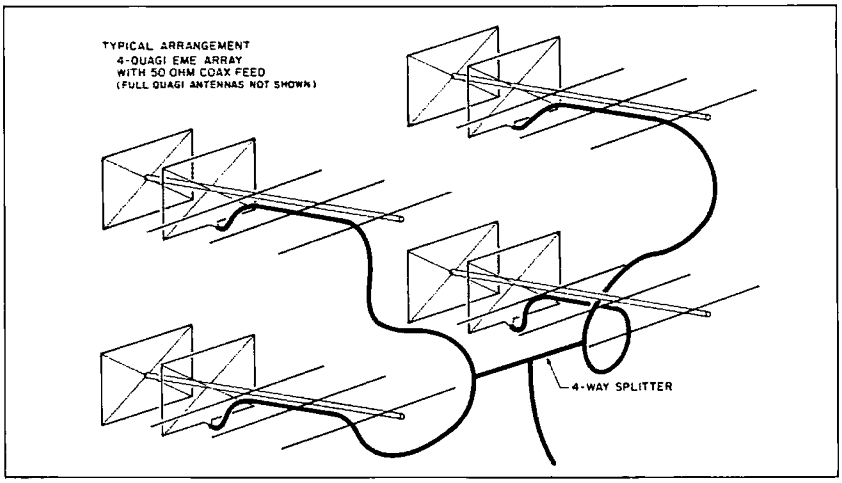

Figure 2. Four quagi EME array with 50 ohm coax feed (full quagi not shown in drawing).

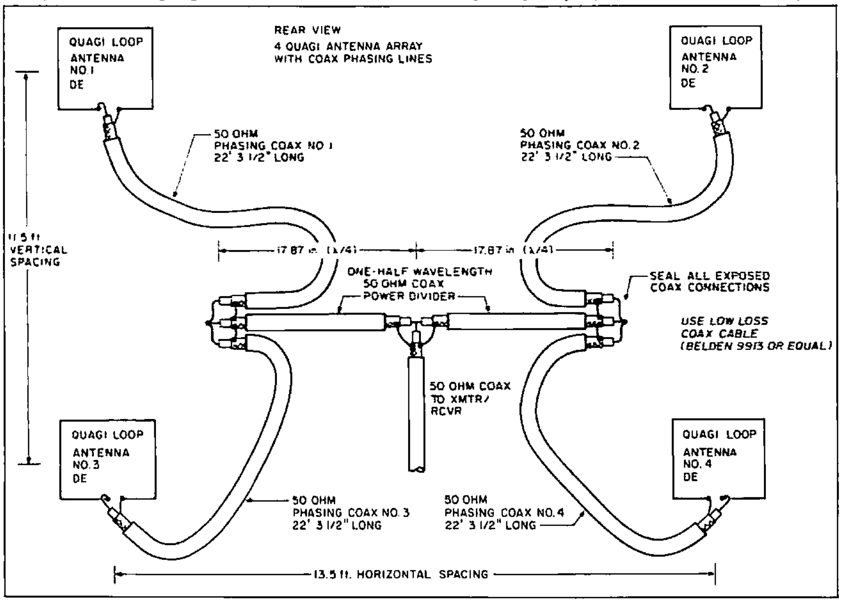

Figure 3. Coax phasing details for the 4 quagi EME array.

up the difference in signal strength levels for EME work. Four good long boom antennas properly spaced, phased, and fed with 500 watts or more, will permit one to make many routine, random EME QSOs on 2 meters. The number of contacts possible with such a station depends upon operator determination and effort.

What is the lowest power station that you can have and still hope for an EME QSO? Well, I have worked a couple of stations who were using a single long boom antenna and running less than 50 watts. In one such contact, W2RS, running 50 watts into a single Cushcraft 32-19 antenna, answered my CQ. I worked another station, ZD8MD, during a schedule. He was running 25 watts to a single 32-19. With higher gain antennas, such as the 42-18XL and the 2M5WL, these contacts could be easily repeated if peak conditions happen to coincide with the schedule time.

Preamplifiers

Your receiver's front end noise figure must be kept below 2 dB if you want to hear those weak moon echoes. If your receiver's front end is not that sensitive, do not despair, a good low noise preamplifier between the antenna and the receiver will perk it up to an acceptable level. Such preamps can be bought or built. They work best if they use GaAsFET transistors, such as the MGF 1302. They also work better when mounted at the antenna, where feedline losses cannot degrade their performance. If antenna mounting is used, some form of relay switching and front end protection must be provided, lest the preamp be blown out by the transmitter power. Many of the solid-state "brick" amplifiers have preamps installed. While these are not usually the best (a preamp with a low noise GaAsFET is the best) they are usually good enough to let you listen to the larger EME stations when conditions are good.

Avoid the use of bipolar transistor preamplifiers. Even though some of these devices can yield noise figures of less than 1 dB, they are susceptible to intermodulation problems, and in some locations can cause birdies to appear all over the 2 meter band. They may work fine if you happen to live in the South Sea Islands where there are no other RF signals, but otherwise, avoid them.

Coax Feedlines

On receive, feedline losses can be overcome by installing the preamp at the antenna. Feedline losses reduce the power transmitted to the antenna, and putting power into the antenna, not out of the transmitter, is what counts in EME work. For example, 100 feet of regular RG-8 coax will have nearly 3 dB of loss at 2 meters.

That means if you start with 100 watts output from your amplifier, you will get only 50 watts into your antenna. Use the shortest possible length of high quality, low loss coax. Your feedline losses should be kept less than 1 dB. As a rule of thumb, Belden 9913 is fine up to 50 feet. Half-inch hardline is good up to about 75 feet. Three-quarters of an inch hardline will work to 175 feet. Beyond that, you will need the bigger stuff. I use a 190 foot length of 1⅝" Heliax from the amplifier to the antenna. Its loss is less than four-tenths of a dB.

Be careful about connectors and power dividers. Losses can increase if a poor connection occurs, or if water gets into connections and power dividers.

Amplifiers

The minimum power you should consider for EME work is about 150 watts. Some commercial solid-state brick amplifiers will produce this. The output of two such bricks can be combined to double the power output, but this can be tricky. If you plan to try it, get the proper information to do it right. For a more serious EME effort, power of 500 watts or more is recommended. Commercial amplifiers are available with power outputs of 1 kW and more, if you're ready for that. Many EME operators have built their own power amplifiers. *The ARRL Handbook* is a good reference for home construction. Sometimes kits are available.

Remember, you do not need high power to start listening for EME signals, or to make contacts with the large moonbounce stations.

Where, When, and How to Listen

EME work on 2 meters is primarily done on CW, sometimes on SSB, but never on FM. Signals are very weak echoes reflected from the moon's surface. To hear such signals requires a receiver with a reasonably low noise front end (most commercial receivers are not good enough, but a relatively low cost preamplifier can fix that). A well-designed antenna in good working condition must be pointed at the moon. This can be done without elevating the antenna if you can catch the moon during the hour or so after it rises, or before it sets. In fact, when there is EME activity, these are the best times to hear EME echoes using a rotatable antenna that cannot be elevated. If your horizon is relatively clear and flat, ground gain enhancement is possible during rise and set periods. Moderate EME activity occurs often on weekends when the moon is

in a favorable sky position. Activity peaks when the moon is within common view of both Europe and North America. Random activity can be found from 144.000 MHz to 144.020 MHz. Schedules are run between 144.020 MHz and 144.100 MHz. Single sideband voice is sometimes heard on 144.105 MHz. I usually operate CW on 144.008 MHz during such times, and also on weekdays after work. Many CQs are called by myself, W5UN, and others during these times.

Schedule Making

EME operation is either random (calling and answering CQs), or scheduled. Let's discuss schedule operating procedures first. Schedules are made in several ways. The best way is to check into the 2 meter EME net beginning around 1730 UTC every Saturday and Sunday on 14.345 MHz. Direct telephone calls to the station you want to make a schedule with is another way. I've set up many schedules with small stations this way. A third way is to request a schedule by mail.

Schedules usually last for one hour, but may be longer or shorter as agreed to by the participants. Smaller stations usually run schedules for one hour. During schedule making, a frequency and time are agreed on, and the two running stations are designated as being either east or west, depending on their relative location to one another. When a schedule begins, the eastern station transmits for the first two minutes beginning at the top of the hour. If the schedule starts at a time other than the top of the hour, the same two-minute periods are used as if the schedule had started on the hour. If you are running a schedule with a station to the east of you, that station would be the eastern station, and you would be the western station. The two-minute transmit/receive sequencing will continue until the schedule is completed or until time runs out.

For successful 2 meter EME QSOs, you're required to exchange callsigns, O's, RO's, and R's. This data must be received and acknowledged by both stations. 73s are usually sent also, but this is optional information. Let's consider a schedule example.

The table illustrates how a schedule between W4ZD in Florida and ZD8MB on Ascension Island might progress, and shows how the information discussed above is handled. Let's say they have a one-hour schedule starting at 1000 GMT. ZD8MB is east of W4ZD, so he is designated as the eastern station, and will transmit the first two minutes. ZD8MB will send calls over and over for the full two minutes (W4ZD de ZD8MB).

W4ZD begins sending at 1002 GMT. If W4ZD heard the calls, he will send ZD8MB de W4ZD for the first minute and a half, and O's for the last half a minute. If W4ZD doesn't hear both calls, he calls only for the full two minutes. This continues until either station has heard both calls and O. Once an O is heard, the station hearing it responds with RO's during his next transmission for the full two minutes. The station copying RO's has received sufficient information for his part of the QSO. When the station transmitting RO's hears an R, that station has received sufficient information for his part, and the QSO is essentially complete. Most stations, upon hearing R's, will respond with R's and 73s to let the other station know that R's have been received.

Random QSOs

Having read all that about two-minute sequences, you will find that a lot of random activity is conducted with one-minute sequences. In fact, nearly all my random QSOs are of the latter type. If stations are hearing each other well enough to copy random calls in one minute, additional time is not necessary.

Random activity is quite a challenge for the less equipped, smaller station. However, by answering the CQs of larger stations transmitting on the bottom 20 kHz of 2 meters, it is possible to make QSOs. It is well-known that the signal level of a scheduled station can be several dB less than that of the weakest identifiable random calling station. A listening operator can mentally fill in the missing parts of a very weak station's call when he already knows what the call will be. Also, when the operator knows a certain station will be calling on schedule, he shifts his ears (and brain) into a more focused, selective mode in order to dig that station out of the noise. For these reasons, small stations are urged to make advanced schedules whenever possible. However, don't give up on answering random CQs, because you never know if success is possible until you try.

I must tell you one more thing about schedules and the pre-knowledge of callsign information: It takes discipline to assure yourself that you're hearing what you think you're hearing when you dig deep into the noise for long periods. Some operators can manage this self-discipline better than others. Remember, you will only shortchange yourself and the station you are scheduling if you acknowledge QSO information that you have not truly heard, but only thought you heard or, worse, have guessed at. This is another reason why I enjoy random operation: I don't have to be as disciplined about what I thought I heard, since I actually must hear the full call to know who is calling.

The Effects of Conditions

A signal of constant strength transmitted from Earth and then reflected back never yields the same signal level in a receiver from one moment to the next. There are many factors which cause this phenomenon. Some of these factors are well understood and predictable. Some are only partially understood and are not so predictable. There are probably a few factors that haven't even been thought of yet. Some of the signal variations are short-term (such as those caused by moon/Earth libation), and some are long-term, such as those caused by Earth/moon distance separation. Libation effects are very short-term (milliseconds) and are of little interest to EME operators. Longer-term factors are of great interest because EME scheduling and operation times are chosen based on a set of such predictable factors. I will explain these factors shortly. There are also some factors which cannot be predicted in advance, but which can greatly affect EME communications. I will briefly discuss these also.

The distance of the moon from Earth, the position of the moon in the sky (that is, the background sky when looking at the moon), and the phase of the moon during its 29-day cycle all have well-known effects on reflected echo strength, relative to system noise. During the 29-day cycle the moon ranges from apogee (furthest from Earth) to perigee (nearest to Earth). At apogee, the strength of a returning echo will be about 2 dB less than it will be at perigee, all other things being equal (which they seldom are). Also, during the 29-day cycle of the moon the background sky noise levels at 2 meters will vary from 175 degrees to over 5000 degrees Kelvin. (The higher noise occurs when the moon is positioned against the galactic plane, which happens near the moon's most southerly declination.) This noise equates to dB readings from 1.75 dB to over 10 dB. Sky noise and path loss are the key data elements used by EME operators to determine the best operating times during the moon cycle.

Factors affecting the moon which are not so easily predictable are the effects caused by the Earth's geomagnetic field as the signals pass through it on the way to and from the moon. One such effect is Faraday rotation. This causes the polarity of signals to rotate from horizontal to vertical and back. Faraday rotation can cause a signal to null-out (or peak) depending upon what type of polarity your antenna has. Polarity seems to rotate quite naturally at about 15 minute intervals when the geomagnetic field is normal. However, things are seldom "normal" with the geomagnetic field (despite what WWV says), and sometimes rotation locks up for long periods of time. Another situation caused by geomagnetic activities is where signals seem to be dispersed or absorbed, rather than rotated. At such times, it doesn't seem to make any difference what your antenna polarity is. Even if you could rotate polarity (as some stations can) it wouldn't help. I have also heard signals greatly enhanced in strength when the geomagnetic field was disturbed, although many times when this happens, communications is one-way, and stations at more northern latitudes will hear nothing for long periods of time. Then the situation reverses, and the southern stations are locked out. So, it is difficult to determine in advance just what the effects will be for a given time and condition. There is still a lot to be understood about such effects on EME communications before predicting methods can take them into account.

There are are a few other rules of thumb about EME operating conditions. Overall, nighttime seems to be better than daytime for EME operation (perhaps because ionization and consequent absorption is less of a problem). But I have heard some very good condi-

tions during daylight, so don't give too much weight to this. Winter, on the average, seems to have better EME conditions than summer, probably for similar reasons.

The new moon can affect EME communications. Noise from the sun will mask weak signals during new moon. The moon is not usable for EME work for about two days centered around the new moon date. There will be many days during the cycle when the moon cannot be seen because it is up during daylight. EME communication is quite possible most of these days, if you can aim your antenna without seeing the moon.

Computer Programs

A number of programs that compute moon-tracking data, essential to scheduling and antenna-aiming, run on ham shack computers. The best of the more modern programs run on IBM personal computers. Other computer software for Commodore computers, HP calculators, and others, can still be obtained, or even easily written.

Good moon tracking programs, such as W5UN's SKYMOON, VK3UM's REALTRACK, and WA1JXN's TRACKER, will give excellent directional antenna-aiming and a lot of other pertinent EME data. *[Ed. Note: see the review of SKYMOON in this issue]* Many EME operators use such programs to find the moon's azimuth and elevation (Az/El) from any given point on Earth at any given time, so that they can arrange mutual schedules. In addition to moon position, these programs give moon apogee and perigee information, and moon background sky noise estimates for each Az/El time interval calculation. Some programs go beyond this and also compute many other variables of interest to EME operators.

EME Directory

"The EME Directory," available from Bev Cavender W4ZD, P.O. Box 88, Lake Placid FL 33852 is a good resource to have if you wish to know who the worldwide, active EME stations are, and what kind of station equipment they are using. The directory is also part of revision 2 of the SKYMOON program.

2 Meter EME Newsletter

"The 2 Meter EME Newsletter," published by John Carter KØIFL, P.O. Box 554, Union MO 63084 about 10 times per year, helps keep EME operators informed about who is active on EME, and who is working whom.

2 Meter EME Net

As I mentioned previously, the 2 meter EME net meets every Saturday and Sunday around 1730 UTC (after the 70cm net finishes) on 14.345 MHz SSB. This is the "watering hole" where EMEers gather to exchange information and make schedules. Newcomers are welcome to check in. VE7BQH is net control. 73

Quorum introduces the first totally integrated system for the reception of weather satellite images directly on your personal computer. Selection of HF NAFAX, GOES WEFAX, GOESTAP, METEOSAT, NOAA and METEOR APT (including satellite downlink frequency selection) are made under complete program control from your PC keyboard.

The easy to learn and use Menu driven program allows you to capture, store, retrieve, view and print images with a few simple keystrokes. Images can be colorized from a palette of up to 262,000 colors when using a VGA display.

System configurations capable of NAFAX reception start at $399.00 while fully capable systems can be configured for $1500 to $2000.00, providing professional quality at low prices.

For complete information and a Demo Disk, call or write:

Quorum Communications, Inc., 1020 S. Main St. Suite A, Grapevine, TX 76051 (817) 488-4861. Or, download a demo from our Bulletin Board by calling (817) 421-0228 using 2400 baud, 8 data bits and No parity.

Receive Weather Satellite Images and Charts on your PC with Quorum's Totally Integrated and Affordable Weather Facsimile System

Hams in Space!

SAREX II, the next generation.

by Philip Chien

At 11:41 a.m. on December 2, the night sky lit up over Florida with a spectacular display of flame and smoke as the Space Shuttle Columbia headed for orbit. After a series of delays (caused mainly by a persistant hydrogen fuel leak), STS-35 and SAREX II-01 was finally on its way! STS-35's primary mission was to carry NASA's Astro-1 spacelab with three ultraviolet telescopes to observe the universe in ways never viewed before. Operating NASA's own Goddard Spaceflight Center's Ultraviolet Imaging Telescope (UIT) was payload specialist Ron Parise WA4SIR. In 1978 UIT astronomer Ron, a ham since 1962, was completing his graduate studies at the University of Florida, and by 1980 he was part of the UIT team. Little did Ron realize then that he'd be flying with the UIT instrument he helped develop.

The UIT is best described as a sophisticated telephoto camera with super-sensitive film and a violet filter. Imagine a telephoto camera with a field of view 25% wider than the full moon with ultra-low-light film with an effective ISO (ASA) of a couple of hundred thousand (in comparison with the 100-400 film you'd normally purchase). It has a filter so violet the human eye can't see it, further into ultraviolet than Hubble's capabilities. Also, instead of an 18 or 36 exposure roll of film, you have a film pack with over 1000 exposures of 70mm film! That's one heck of a telephoto camera!

SAREX II

The launch of the Astro 1 mission marked the beginning of a new series of SAREX (Shuttle Amateur Radio EXperiment) flights.

The primary mission of this SAREX was to communicate with a number of classrooms across the U.S., as well as to provide hams worldwide a way of directly connecting up to the shuttle via a packet radio robot.

In addition, Ron recommended trying ship-to-ship contact between *Columbia* and the Soviet space station *Mir*. He said, "The idea came to me some time ago, just because here was *Mir* operating 2 meters and we were going to be operating 2 meters, and we ought to talk to each other."

Any *Columbia*-to-*Mir* contact would be much easier from the Soviet side than from the U.S. because *Mir's* ham shack includes a 25 watt transceiver and an outside antenna, while the *Columbia* has an inside antenna and 5 watt transceiver.

Photo A. Ron Parise WA4SIR working the world from the SAREX operating position onboard STS-35. Photo courtesy of NASA.

Photo B. Mission commander Vance Brand talks with family members via the SAREX 2 meter link. Photo courtesy of NASA.

Contact between the two vehicles is complicated by two factors. The most obvious problem, the Doppler shift, actually turns out to be fairly insignificant. More complicated is the motion of the two spacecraft. Since the spacecraft are in different orbits at different altitudes, and traveling in different directions, the range between the spacecraft and the line of sight angle changes quickly: One minute you're several thousand kilometers from each other, the next you're right next to each other, and then you're several thousand miles away again.

Low Inclination

Unlike the earlier ham radio shuttle flights, Astro was launched into an orbit with an inclination of 28.5 degrees, the typical orbit for most shuttle flights. Spacecraft launched to the east gain extra payload capacity due to the Earth's rotation: A spacecraft launched due east can carry the most payload; the orbit is inclined to the equator at the same angle as the latitude of the launch site. The end result is that Astro flew no further north of the equator than the KSC launch site, and at the same latitude to the south, 28.5 degrees. The Spacelab 1 mission with Owen Garriott W5LFL and Spacelab 2 with Tony England W0ORE flew into higher inclination orbits for better Earth observation capabilities, the trade-off being less payload.

The irony is that the Soviet space station *Mir* is in a 51.6 degree orbit, halfway between the Spacelab 2 and Spacelab 1 orbits. Had Astro been launched into a higher inclined orbit, longer opportunities for *Mir* contacts could have been possible.

Photo C. Matt Flagg, a senior at New Prairie High School in New Carlisle, Indiana, and Jim Fonte KK9T (r) make the first school contact with WA4SIR in the shuttle Columbia. Teacher David Washburn WB9QJL (l) looks on during this historic contact. Photo by Steven Peterka WD9FGZ of the News Dispatch.

Due to the 28.5 degree orbit and Ron's schedule, he was awake primarily when flying over Australia, South America, and Southern Africa; however, Astro's altitude made it possible for most continental U.S. hams to contact SAREX within line-of-sight requirements, even though it was at relatively low angles.

Schools and Packet

Since the 1985 Spacelab 2 flight, many improvements have been made to the space ham equipment, expanding the capabilities for SAREX contacts. For example, the original antenna on Spacelabs 1 and 2 could only be used in the overhead windows, which interfered with Earth observations. The new antenna (made by the Motorola Amateur Radio Club in Shaumburg, Illinois) mounts in a side window where it's out of the way and doesn't require any particular orientation. Ron did have minor problems moving the antenna across the flight deck, crowded as it was with crew and equipment, to other windows, but he managed to do it without interfering with Astro operations.

In this latest mission, relay links with teams of Australian, South American, and South African hams relayed the SAREX signals back to classrooms via an elaborate telephone/radio linkup. Most important for computer-oriented hams was the addition of the packet mode, including the capability to operate SAREX in its robot mode continuously during Ron's shift without interfering with his other responsibilities. The packet TNC was a Heath HK-21 with special robot software written by Howie Goldstein N2WX.

As it turned out, Astro was launched just a couple of hours before the Soviets launched their TM-11 mission with Victor Afanashev and Musa Manarov, a handle familiar worldwide with hams. He flew a year-long *Mir* mission in 1988 as U2MIR/UV3AM.

Record Numbers in Space

The dual launches on December 2, 1990, resulted in 12 people in orbit at the same time in three separate spacecraft: seven Americans aboard *Columbia*, two Soviet long-term cosmonauts finishing their mission aboard *Mir*, two Soviet long-term cosmonauts starting their mission, and a Japanese journalist aboard the TM-11 Soyuz spacecraft.

On the second day of the *Columbia*'s mission, *Mir* passed within 50 km. Mission specialists Jeff Hoffman and Mike Lounge said that *Mir* looked like a moving star. Unfortunately, they couldn't attempt a 2 meter contact because the Soviet crew was busy performing their post-docking tasks. Since contact would be possible *Mir* later in the mission, the attempt was rescheduled.

First Contacts

While the Astro crew didn't get a chance to talk to *Mir*, thousands of ground-based hams around the world were able to communicate with Ron Parise aboard the *Columbia*. Hundreds of students, teachers, and individuals spoke with him directly during brief contacts. Ron used some of his spare time, before sleep and after waking, and before going on 12-hour duty, to communicate with the world. He operated SAREX every time he had a couple of spare minutes.

After Ron got a chance to set up the SAREX gear, he prepared for his first voice contact as he passed back over the Kennedy Space Center launch site. His first voice QSO was with NZ8W, a ham operating a 45 watt car rig outside a hotel near the launch site. Appropriately, NZ8W happens to be Henry Parise, Ron's dad.

Due to the tight crew schedule, the other astronauts didn't get a chance to use SAREX much except for pre-planned phone patches with their families.

One of Ron's more unusual voice contacts was with mission manager Jack Jones KC4IWU. Normally mission managers only talk to the crew through the spacecraft controllers and capcoms, but Jack went over to the Marshall Spaceflight Center's ham shack and talked with Ron for a couple of minutes about how well things were going, and how proud the ground team was of the job the crew was doing.

One lucky young ham in Hawaii, newly upgraded to Technician, contacted Ron. Thoroughly enjoying himself, Ron talked for a couple of minutes about activities aboard the shuttle. Unfortunately, due to technical

Photo D. Charley Shumaker N8IKP, Barbara Curry N4TCC and Ron Curry WA4GSS (standing left to right) discuss the joys of amateur radio with students of several schools from the Huntington, West Virginia, region just prior to making contact with STS-35 during 2-way session number 3. Photo courtesy of Ron Curry WA4GSS.

Photo E. Fifth grader Crystal Stuart of Everett, Washington, anxiously waiting to talk with WA4SIR. Thousands of students in the Mukilteo School District #6 listened in via 2 meter rigs, donated by ICOM, located in many area schools. The Evergreen Intertie (linked repeaters connecting the northwest U.S. and Canada) allowed students in Washington, Oregon, Idaho, Montana and Canada to listen as well. Photo courtesy of Larry Luchi W7KZE.

problems aboard the orbiter, Ron wasn't able to record the conversation or copy down the callsign. If you're that ham or know who it was, please contact Ron!

During the mission Ron had the chance to make several sets of voice passes over the U.S., a couple of passes over Australia, and two over South Africa. Ron even made contacts with some portable rigs. When Ron tried a few free-for-all uplink contacts, literally thousands of hams transmitted at once on one uplink frequency. Ron said at times it sounded just like white noise on his end.

Besides individuals, Ron made 28 prearranged contacts with student groups around the country, primarily via voice relays through Australia (VK2AS, VK5AGR and VK6IU) or Brazil (PY2BJO), although one contact was made directly from the *Columbia*. One of the teachers at Tampa Palms Elementary School in Tampa Florida is Cathy Blair, astronaut Sam Durrance's sister. At 8:42 p.m. EST on December 8 (6 days 18 hrs. 55 minutes MET), Ron called Lee Paulet KB4FBX, who had set up a rig in the schoolyard with the assistance of Robert Osband N4SCY. With the help of two other hams, N4SCY provided a real-time computer display showing the shuttle's position.

After Ron made the initial contact with Lee, he passed over the handset to Sam, who talked to the students for about four minutes, before the shuttle went out of range. Ron said, "It was natural to let him [Sam] talk to the kids and answer the questions."

Though it was a Saturday evening, approximately 200–300 students came over with their families to hear the shuttle in person. Local and regional newspapers, radio stations, CNN and television stations from all three networks covered the contact. Several students asked Sam questions about life aboard the shuttle, and everybody was entertained—and educated. While the contact took up four minutes of valuable shuttle time, it helped educate hundreds of students, and indirectly affected thousands of others who learned about this SAREX contact with a small elementary school in Florida. This is one of the fine examples of how the SAREX experiment has helped educate the public about the space program and ham radio activities.

Packet Robot

One of the most exciting aspects of the flight was the capability to operate the SAREX experiment almost 16 hours a day, even when Ron was on duty. Packet radio made it possible for Ron to leave the rig running as a mini-packet BBS while he was busy working with the Astro telescopes. (For details about SAREX hardware and procedures, see the article "SAREX-90" in the May '90 issue of *73 Magazine*.)

The SAREX TNC held two lists of contacts: a work list with a capacity for 600 confirmed QSOs, and a heard log for up to 32 incomplete QSOs.

The work list holds the names of the 238 lucky hams who completed the entire contact, acknowledgment, and receipt of acknowledgment procedure (see "Hamsats" in this issue). The heard log held the last 32 hams who made contact, but who hadn't completed the entire procedure. The heard log was broadcast as a QRZ beacon with its current list. Whenever Ron got a chance in between observations on the shuttle's flight deck, he would go down to the middeck where the SAREX experiment was located and dump the heard log from the TNC to the PGSC (Payload General Support Computer), a modified GRID laptop computer. The PGSC, onboard the shuttle since 1983, has proven itself so useful in monitoring experiments and collecting data that NASA is planning to replace the French-built DDS (Data Display System) Spacelab computers with them.

Ultimately, Ron got 672 callsigns in the stored heard log, including duplicates. The ROBOT's counter exceeded 1700 contacts. Unfortunately, he couldn't constantly dump the log, and it kept overflowing. The only record of the lost log entries is the QRZ beacons, and they're needed to reconstruct the log. Ron told me, "We need any QRZ beacons that anybody's got on disk or in hardcopy." If you've received and copied a QRZ beacon PLEASE send a hard copy to the ARRL, 225 Main St., Newington CT 06111. Or send it via packet to *SAREX @W3IWI.MD.USA* or SMTP Internet mail to *SAREX@TOMCAT.GSFC.NASA.GOV.*

Astro's final target, the comet Levy, was high-risk. Ironically, each of Astro's launch attempts involved a comet: Halley's in 1986, Austin in May 1990, and Levy in September 1990. When Astro was launched in December, Levy was too close to the sun to permit safe observations. However, the managers decided to attempt observation of Levy, since, as the last target for the mission, it wouldn't matter if the sensors were overloaded.

Unfortunately, while everything was working fine in orbit, the weather on the ground didn't cooperate. Mission controllers decided to bring *Columbia* back a day early to avoid the bad weather.

A more important impact to the reduced length of mission was the failure of the *Mir* contact, scheduled for nine days into the flight. The Johnson Space Center hams responsible for SAREX were unable to complete arrangements for a quick, last second *Mir* contact on the final day, even though they went as far as phoning their Moscow contacts.

Columbia completed its tenth spaceflight, and the Astro mission, on December 10, 1990, at 9:54:08 p.m. PST, when it landed on concrete runway 22 at Edwards AFB in California. When Astro flies again, backup payload specialist Ken Nordsieck will fly with either Ron or Sam. I asked Ron if he'd like to fly with SAREX again, and his reply was an enthusiastic "Sure!"

Philip Chien is an aerospace and technical consultant with over 350 published articles in the aerospace and computer industries. He has covered the space program from the Kennedy Space Center since 1983, and computers and telecommunications since 1984. He has been promising to get a ham ticket for the past two decades, and will take the tests "any day now." Honest. Look for a callsign before the next SAREX flight.

ELTs and EPIRBs Revisited

Right now it's evening and I'm looking out the window of an L-1011 jumbo jet that has just taken off from the Dallas-Fort Worth airport. Reflections from street lights in the new subdivision below make the roads stand out like dotted lines. I wonder if anyone has put on a hidden transmitter hunt in this part of town yet.

Thinking of flying and foxhunting makes my mind wander back to a night in the summer of 1982 when I was among a group of hunters waiting for the last vehicle to find the T on a hillside in rural Yorba Linda, California. We idly noticed a Cessna four-seater above the hills to the east.

All of us then looked away except April WA6OPS, who saw it abruptly nose over and disappear behind a hill. A few minutes later we heard emergency vehicles on the freeway below. Still later, we learned that the plane had crashed near the freeway, killing all aboard.

That mishap occurred very close to a populated area, and nothing could have been done to save the victims. But aircraft, boating, and hiking accidents often have survivors who need to be located and rescued from dangerous situations before their injuries claim them. That's where skilled volunteers who know radio direction finding (RDF) enter the picture.

"Homing In" readers are interested in search and rescue (SAR), and they have strong opinions. I know, because they responded in record numbers to the October and November 1990 columns on the subject. In those issues, I explained impact-activated 121.5/243.0 MHz Emergency Locator Transmitters (ELTs) for aircraft, and their maritime counterparts, EPIRBs. I told about a new Personal Locator Beacon (PLB) service for hikers and campers, called PELTS, that was originated by KA7OSM and proposed officially, in a much different form, by the FCC. I asked you to let me know your thoughts.

Reader Reactions

J. C. Arenburg W4DZA, a major in the Civil Air Patrol (CAP) reminded me to mention that an injured person's chances of survival go down by 80 percent in the first 24 hours, so the rescuers' speed is vital. "Constant practice is important," he writes.

Henry Mosely KA1RRT of Grafton, Vermont, sent along a page from a catalog he received, advertising for $100 a "Human Emergency Locating Transmitter" that "can save your life." The ad goes on to say: "Transmits SOS via satellite to US Air Force Rescue Center. Rescue teams 'home in' on your signal. Field tested and government approved."

Government approved yes, but only for aircraft or boats in distress, not individuals. The ad fails to mention the $10,000 fine that can result from improper use. "Hunters and hikers will be (accidentally) turning them on in their tents," he worries. These ELT clones transmit continuously when activated, so the signal from a false alarm can cover up a legitimate distress signal.

On the other hand, many writers are concerned that there is an excellent satellite-tracked emergency beacon service for boaters and aviators, but nothing similar for wilderness users. Bruce Wright N8MWL is a frequent backpacker. He is working on a QRP ham rig for hiking, instead of buying an ELT clone. But he would prefer to be able to call for rescue on the frequency that is presently most likely to evoke a response: 121.5 MHz.

"It would not matter if it is illegal," Bruce wrote. "A jail cell would be a welcome alternative to most emergencies. This attitude is why so many ELTs are in use (by hikers)." N8MWL wants a separate satellite-tracked and aircraft-monitored PLB system for the general public that could get response like the 121.5 MHz system does, and adds, "There's no reason for aviators to have a corner on the lifesaving market."

Almost no one liked the FCC's PELTS proposal, which called for PLBs with nine ACSSB voice channels and one homing channel near 220 MHz. Typical responses: "If it had been approved, PELTS was going to be a total, absolute disaster!" and "I agree with you on PELTS. No voice!"

By far the most deeply-researched response came from Lou Dartanner N6ZKJ.

Lou sent a four-page typeset document titled "Personal Locator Beacons—A Status Report," which she prepared for her company. It gives a wealth of general information about PLBs, and summarizes the discussions at a full-day seminar on the subject put on by the International Committee on Search and Rescue (ICSAR).

Every paragraph is packed with useful information. There is no way I could cover in this limited column space the depth of thought and analysis that has gone into the ICSAR seminar and N6ZKJ's report.

What are other countries doing to implement PLB systems? Will inexpensive PLBs encourage hikers to take unnecessary risks because they can easily call for help? Should there be fines for persons who generate false alarms with PLBs?

Did you know that alerting and homing systems using call boxes and short-range transmitters are now being developed and tested for use within the confines of national parks and small wilderness areas? This report gives more details. What are the liability issues faced by responders to PLBs?

Could SAR organizations be sued for not rescuing someone in time? That's in the report, too.

The report also tells about global locating systems on the drawing boards from several companies, including Orbital Communications, American Mobile Satellite Corporation, Atlantic Research Corporation, Qualcomm, Geostar, Starsys, and Motorola. If you would like a copy of N6ZKJ's report, send an SASE to L-tronics, 5546 Cathedral Oaks Road, Santa Barbara, California 93111, and ask for the report by name.

Lou recognizes the potential for overload of the present 121.5 MHz SARSAT system, but would still like to see it used for wilderness PLBs, since SAR teams are already equipped for it. Equipping volunteer rescue teams for a new system on a different frequency would be costly, she says, and would slow the implementation of this badly needed service. If ELTs and PLBs transmitted intermittently instead of continuously, then false trips would not "jam" emergency transmissions.

Photo A. It's that one! Steve Kirkman KB6IMB (left) and Jim Frank KB6ONC of the Los Padres Search and Rescue Team have found another squawking ELT at the Santa Barbara airport with their L-Per RDF set. (Photo courtesy N6ZKJ and K6IA.)

Ask An Expert

Lou Dartanner knows a lot about hunting for ELTs; she has done it for almost 20 years. Lou and her partner Bruce Gordon N6OLT founded L-Tronics when ELTs became mandated for certain aircraft in 1972. The SAR community needed a complete, lightweight RDF unit that could be used in vehicles, on foot, and from aircraft.

Bruce designed the "Little L-Per," and Lou built the first 100 units. When they sold out immediately, Bruce and Lou knew they were headed for success.

Today the L-Per, with its two switched vertical antennas, is the "standard issue" RDF set for CAP and SAR groups all over the USA and the world.

The L-Per's self-contained four-channel crystal-controlled receiver was designed for popular SAR training and operational frequencies, such as 121.5, 121.6, and 243.0 MHz. But, with a change of crystal and a little tweaking, it will work on the amateur 2 meter and 1¼ meter bands. Despite its four-frequency limitation, many RDF competitors rely on L-Pers for on-foot sniffing duty during foxhunts.

Lou has not given up on her commitment to SAR. In fact, she is more active than ever, and says, "I still learn something every time I go out." Dedicated volunteers like N6ZKJ make the Los Padres Search and Rescue team (LP-SAR) one of the most active and well-respected groups of its kind in the country. (See Photo A.)

LPSAR, an auxiliary of the Santa Barbara County Sheriff's Department, has a Memorandum of Understanding with the Santa Barbara Amateur Radio Emergency Service. ARES members become part of search teams to provide vital communications and RDF services. It was her desire to be able to use Amateur Radio for SAR efforts and to facilitate ELT alerting that led Lou to get her ham license.

Early Warning

According to N6ZKJ, a majority of ELT/EPIRB trips occur in the early afternoon, but SAR groups are often not activated for several hours while satellite fixes are performed, the FAA checks flight paths, and the callout request goes through the chain of command. When volunteers are alerted in the evening and nighttime hours, it's harder to organize the team because facilities are less accessible than they are during business hours.

To reduce the delay, L-Tronics developed an automatic alerting system for Santa Barbara County hams. A 121.5 MHz receiver is incorporated as part of the K6TZ repeater, overlooking Santa Barbara Harbor. When an ELT or EPIRB signal trips the receiver, the

Third Term for the C-64

As we go Marching along, I find myself mired in a pile of letters! To wit:

Rick Arzadon WA8RXI of Taylor, Mississippi, says he reread the "RTTY Loop" column of November 1989 and became interested in the "ThirdTerm" terminal program originally offered by Jack Skubick K8JS for the C-64 computer system. According to Rick, Jack no longer has a C-64 system, and therefore no longer provides "ThirdTerm" for it. Rick is looking for a source of this program.

I don't have a Commodore system here, so I really can't help on this one. I would love to hear from some of you, though, who could provide this shareware program to fellow readers.

Rick also says that he has a receive-only packet program and interface obtained locally for VHF reception, and that he is looking for a multimode terminal unit. He asks that age-old question, "Of the three controllers, the AEA PK-232, Kantronics KAM, and MFJ-1278, which one has the best overall performance receiving and transmitting?"

The simple reason that I have never directly answered this question is that I do not have the data. While I have one of the three controllers here at WA3AJR, the only information I have on the others has been picked up from conversations with other hams, advertisements, and review articles. That I know of, no one has ever done a real head-to-head comparison of these three top-end machines, and in all likelihood, there may be no real point to doing so. I suspect, from what I've seen and heard, that differences in terms of signal acquisition and decoding are minimal. There may be bigger differences in features or operations, but that gets more into the line of personal preference than true ratings.

So, I guess the bottom line is to see if you can find someone with a unit you have in mind, go over to their shack, and play with it for a while. Like a car, some folks prefer Chrysler, some GM, and others Toyota. None of these are better or worse, just different.

This, That, and Something Else

Speaking of "different," I received a letter from S. Roy Luxemburg N5QQM currently residing in Singapore. In part, Roy says that [thanks to "RTTY Loop,"] "I purchased a Model 35 from Western Union in 1981. I had thought to use the former TWX service with WU, and . . . [also be able to] . . . connect it with ham radio. Talk about lamentable ignorance! I still have the machine, but it turned out to be *almost* a white elephant.

"In an attempt to follow my keen, if unfulfilled, interest, I continued to slowly accumulate information and equipment. Then came the wonderfully informative issue of *CQ Magazine* for November 1983. That did it. I bought a HAL CWR 6850 . . . and got a clue about SWLing with RTTY!

"But I wasn't there yet. My subscription to *73* ran out and I decided not to renew after several years. To make matters worse, I had allowed my license to lapse (sheer negligence in the light of the foregoing!) and recently re-acquired a license. Now I also have a Tono I5000E and two, count 'em, *two* AEA MBA-RCs for code conversion.

"I then built a Heath Ultramatic Keyboard to get from Morse to RTTY and ASCII. Along came AMTOR—great, but I think RTTY is still the best.

"Reading your column this morning was a costly enterprise. Hll I spied *73* in a magazine rack on Orchard Road, a great shopping area here in Singapore. The price of *73* was S$10.60, which is more than $6 in the States! That did it. I'm subscribing again, today.

"We are rich in vacuum tube equipment at N5QQM, having about 25 Collins and Hallicrafters receivers, two KWS-1s, SR-400A, four or five HT-32s, one HT-20, and an HT-1 (!), as well as a 32V2 and 32V3, CE200V, and on and on . . . .

"Do you ever write about the old gear? FSK generation for the old vacuum tube transmitters, possibly? How about stuff on the many special things you've done with the old stuff?"

Well, Roy, about the most impressive thing I've done with the "old stuff" is get rid of it at the wife's insistence. But seriously, I have covered the gamut here, from shift pot circuits to tuned tanks. I am always willing to re-examine an old topic, so just let me know what turns you, or your system, on.

Computers and RFI

Another note, this one from Dick Peters WA1PWF of Norfolk, Massachusetts, deals with the eternal question of RFI. Dick tells us that he is using a Tandy 100 laptop for RTTY, AMTOR, and packet, and he would like to go for a big PC clone, but wonders about RFI.

He is aware of the FCC classifications of computer equipment as Class A or Class B, and wonders how they relate to practical considerations in the ham shack. Dick has an old TRS-80 which is "horrendous" on the HF bands, and which makes him edgy to lay out "big bucks" for a more modern machine.

Well, Dick, in general the FCC guidelines are probably the best thing you've got going for you. Some time back we covered the specifics, and I'll go through it again if a bunch of you want me to, but the long and short of it is that the guidelines for FCC Class B are at least much better than Class A in reducing unwanted emissions. This means a lot if you are trying to pull the weak one out of the mud. Class B computers are the only ones certified for home use. So, if someone tries to sell you a Class A computer, or worse yet, an uncertified computer, just say no. Sorry, but that kind of tsoris *[trouble, distress, woe, or misery, according to* Webster's New World Dictionary*—eds]*, you don't need.

We'll cover more of this craziness next month, and try to respond to some of the things you have asked about. I especially appreciate the comments, questions, and suggestions regarding simple little devices and circuits of use to the RTTY-o-phile. Some of the best of them may well be gracing a future "RTTY Loop." In the meantime, keep them coming by mail, to the above address, or on Delphi (username MARCWA3AJR) or CompuServe (ppn 75036,2501). Graphics as PCX, TIF, or GIF files are welcome as well.

Homing In

Continued from page 59

repeater automatically pages LPSAR hams. At the same time, it dials into N6ZKJ's computer, reports the time and strength of the ELT signal, and sends a sample of its audio.

LPSAR has added three other remote ELT/EPIRB monitors, including one on the CAP repeater atop Santa Ynez peak. The Santa Ynez repeater has automatic paging, while the other two are tied to the computer via landline. The computer keeps careful records of all alarms, and facilitates comparison of the signals from the remote sites to pinpoint the signal source. Says N6ZKJ, "This SAR team takes each ELT signal seriously."

The next logical step would be remotely-operated 121.5 MHz direction finding equipment at the receiver sites, right? The Santa Barbara hams have already of thought of it, of course. But it's tricky. Sensitive RDF sets with switching antennas usually do not perform well next to high power transmitters at typical radio relay sites. Despite the technical problems, they are making progress, and I hope to be able to report success in a future "Homing In" column.

Pioneer Hams

The Santa Barbara remote alerting system has been so successful that it has become the prototype for a nationwide network, with L-Tronics as the prime contractor. Sixty-four ELT monitors are now in place at airports in 38 states, with more in the planning stages. Each unit dials a computer at the FCC in Washington and sends data when it hears an ELT or EPIRB. Who says we hams don't make technical innovations any more?

There is lots more to tell about the good work of LPSAR, but it will have to wait until another time. Meanwhile, hats off to Lou and others around the country who use their T-hunt talents for this important public service.

And thanks to everyone who wrote in about SAR RDF. Keep the cards and letters coming, and find out how you can help fill the SAR needs in your area.

As W4DZA put it: "There is nothing quite like the thrill of hearing someone say on the radio, 'The chopper/ground search team is on the way to base with a survivor,' and to know that you played a part in possibly saving a life."

NEW From Micro Computer Concepts RC-1000 REPEATER CONTROLLER

• Autopatch
• User Programmable CW ID, Control & User Codes & Timeouts
• Intelligent CW ID • Auxiliary Outputs • Easy to Interface • Remote Base/Tape • Reverse Patch • Tailbeeps • 12 VDC Operation • DTMF Decoder with Muting • Telemetry • Control RX • Response Tones • Programmable COS Polarities • Detailed Application Manual with schematics • 90-Day Warranty

Never Say Die

Continued from page 4

glee over your latest choice of directors—most of whom you let run completely unopposed. Wow, talk about apathy!

Bigotry 1991

Yes, I know we're not supposed to talk about race, politics and religion over the air. Heck, people get holy hell just for writing about it. These are areas where few people are able to think and most just react. . . usually negatively. Hate.

We can cover it over if you prefer, but the fact is that I'm hearing more racial slurs over the air these days than I can ever remember in the past. I'm not talking about racial jokes, no matter how tasteless. Alas, we seem to have built up a sensitivity to even the slightest hint of a slur against a race or group. I wonder if Randy Newman's "Short People" would even get played on the radio these days?

Comedians are having a terrible time. They can't joke about blacks, Jews, Catholics, women, gays, cripples, lawyers, doctors, morons, drunks, drug addicts, Italians, Poles, Arabs, Mexicans. . . without being accused of being insensitive. Andrew Dice Clay is a natural result of this oversensitivity syndrome. This is why he is able to convulse audiences.

This is also why, I suspect, we're hearing so much insensitivity over the air. Oh, some of it is the Archie Bunker mentality sounding off, but much of it is just hams fed up with sensitivity and wanting to stir things up. Old-timers will remember W2OY, who made a career of angering anyone who's goat was on a short tether.

As a rich, conservative American WASP, I'm a ripe target for almost every group to hate. I'm white, so most blacks hate me automatically. Hispanics too. You can imagine how long I'd last in Baghdad today. Or Tehran. Even in Paris it's safer to wear a Canadian maple leaf. You don't get treated quite as lousily.

The poor hate me for being successful. They're not willing to put in the work I have, so they can only hate me for having worked so hard for so many years.

The Muslims hate me for coming from a Christian country. . . and never mind my own religion. Let's kill him, just to make sure.

The Chinese hate me for being an American, being white and being a capitalist. Think I'll just stay away from China for a while. Since as a country (with the exception of Bush) we're mad at China for killing all those students, it's safe to make fun of the Chinese. And the Iranians. No one is going to accuse us of insensitivity if we dump on Iranians, right? Or Iraquis. Seems like rather fickle sensitivity to me, but then perhaps I'm oversensitive to sensitivity.

Was it unfair that the Bush team beat Dukakis over the head with Willie Horton? Was that insensitive? Or was that a fair attack on a governor who let his liberal political beliefs blind him to the danger to society he was turning loose?

When I was young I never had any reason to fear going anywhere in New York City. Blacks and Hispanics were just other people. Now, together with every other white person in New York, when I see a group of blacks coming along the street or in a subway car, I'm afraid. I know I'm at their mercy and that no one is going to take a chance with their lives to help me. The blacks know they can do anything they want. Is it bigotry that is involved, or the knowledge that the overwhelming percentage of crime in New York is black instigated? I believe in those odds and stay away from New York as much as possible to keep them low. One of the best moves of my life was to New Hampshire almost 30 years ago. . . after having lived in New York for 30 years on and off.

Amateur radio in America is a white hobby. We may have 13% blacks by population, but I'd put the black ham population at well under 1%. Should we feel guilty about this and make a big effort to recruit black hams? Should we start pushing for more Hispanic hams? More women? More gay hams? Ha, gotcha that time. . . I know you don't want more gays. I made a lot of enemies when I wrote an editorial explaining that sexual preference seems to be programmed in genetically, so give 'em a break. Whew, did I get a bunch of hate mail on that one!

I explained last month that men and women have a great deal of difficulty talking. . . not just over the air, but to each other anywhere. The two sexes are so basically different in goals that communication between them, even in marriage, is a major problem.

With men it's macho on the line all the time. With women it's a need to be loved. Men basically don't need to be loved, they want to conquer. I know I should write the whole book on this instead of presenting it in shorthand in order to head off hairsplitting emotional arguments, but that's what we're up against. . . and one of the major reasons why we have so few women on our bands.

Men constantly try to one-up each other in contests, pile-ups, certificate hunting, broadcasting bulletins. . . and in being outrageous on the air. The worse we are on the air, the more we are trying to cover up our own inferiority feelings. And, feeling inferior, obviously we'll put down anyone who is different. . . by race, accent, color, sex, size, religion, politics. Where is W2OY when we need him. . . to help blast those moronic, short, fat, black lesbians off 14.313?

Perhaps the FCC will recognize the terrible social travesty here and insist on affirmative action, stopping any more whites from getting ham tickets until we're up to 13% black. It would be insensitive to do anything else, right? How do we have the right to all these public radio frequencies when we have remained firmly unintegrated?

Will blacks demand a lowering of the technical barriers on the basis that they are unfair and have been keeping them out? This is what has been happening in other similar cases. If the blacks can't make it, we lower the barrier. . . but just for blacks.

Then we'll certainly hear from the women, demanding a further halt on men being licensed until we're up to 50% women. And what can we reply when they charge that a small, exclusive old white man's private club has been unfairly given use of hundreds of billions of dollars of government property?

What percentage of Hispanics will affirmative action force us to recruit? American Indians? Koreans? Cambodians? That's crazy, they wouldn't dare mess with our small, private men's club—would they?

Mad yet? Well, I'll try harder next month. H.L. Mencken wrote, "A sense of humor always withers in the presence of the messianic delusion, like justice and truth in front of patriotic passion."

And The Winner Is. . .

We had two big winners recently which were financed by the bountiful ARRL coffers. These seemingly bottomless money pits, enthusiastically funded by the ham industry and a docile membership, made big winners out of the ARRL's law firm, even though it went down to a totally predictable defeat in the really dumb effort to fight the FCC in court over their 220 MHz decision.

The FCC, not liking to be sued, particularly where such a big cover-up of political influence was involved, has thus been even further estranged as an ally to amateur radio. Talk about biting the hand that feeds us! It's like kicking the judge on your case in the crotch out in the parking lot just before you go on trial.

The other big winners of the month were the ARRL directors, most of whom ran unopposed (again), and are thus back at the old Newington feeding trough, gleefully dividing up their share of your (and industry) yearly donations.

It's no wonder the directors have such a low opinion of the membership and talk of them as mindless sheep they can manipulate in any way they want. It's a terrible thing to consider, but perhaps they're absolutely right! The 1990 election, if we can dignify the travesty with that name, would seem proof positive that the membership could care less what happens to amateur radio.

Yes, I see those furtive looks and sense your surliness. I'm saying, "Bad dog," and you're feeling guilty and a bit defensive over the mess you've made. The guiltiest of all are the Rocky Mountain members who allowed Marshall Quiat to run completely unopposed. I couldn't believe it! I wouldn't have been any more surprised if they'd run good old Charles Keating for the job! Or Saddam Hussein. Obviously there is no sense of shame in Denver. . . maybe something to do with Bronco guilt, I don't know.

Oh sure, go ahead and get mad at me. Sure, shoot the messenger, but whatever you do, don't read the message. Hey, when things are going good, I'm a great cheering section. But when they're bad, I'm not going to be part of the cover-up. I tell it as I see it and I have a discouraging record of being right. If you bet with me you'll usually win. If you bet against, you're looking to lose. And if you think that's old Uncle Wayne's ego again, start reading my old editorials and see how often I've been wrong in my predictions.

Now, when half of the directors come up for reelection this year, will half the membership go blind and dumb again? Or are you going to start looking around for someone to run against the incumbents? We need some new scoundrels in there at the ARRL trough.

Oh yes, there was a rumor going around at Christmas that President Price would be replaced at the January director's meeting. It was a nice Christmas present, even if it turns out to be a bum steer. Maybe they'll elect Quiat. Why not expect the worst and then be pleasantly surprised if the disaster comes short of it?

Prodigy

My wife (Sherry) is up to here in Macintoshes. Fortunately we live in an area of the country where there are more computer experts per square mile than Silicon Valley, so she's had plenty of help getting her Macs going.

She uses 'em mostly for desktop publishing to support the one hundred how-to-dance videos she's produced (so far). But she also gets trapped by computer games. Then came Prodigy, with its local phone number. Now her Mac is connected to the BBS for hours a day.

As much fun as RTTY was while I was involved, I sensed that I had to cut the cord. It just gobbled up too much time. I'd get typing away to friends on RTTY and the next thing I'd know it would be 4 a.m. That wasn't the way I wanted to spend my life.

When BBSs came along I tried one and found myself in the same quicksand. Whoa, boy! Yeah, it's fun to sit and chat. But it doesn't do much toward helping me to accomplish my goals. Of course, if you don't have any goals other than marking time until you die, a BBS can be a great way to get rid of large gobs of time.

Prodigy is the BBS the users love to hate. It's slow, expensive, your stuff is censored by dictatorial morons, you can only send short messages, and it sure isn't user-friendly. Fax communications beats it all hollow for my money.

On the positive side, I found some old friends there. Alas, I found the need to keep messages short. There's no way to discuss ideas intelligently in a few paragraphs. Using Prodigy is more like conducting a chess game by mail.

You can leave messages for me on Prodigy at JJMK68B. . . or fax (603) 525-4423. . . or by mail in Hancock NH 03449. I'll get 'em all. Please don't (do not) phone. I hate the telephone. Also, I travel, so don't expect quick answers. For instance, in January I was in town the 8th, 15th, 16th, 24th, and 25th. With 16 current publications (all requiring lengthy editorials), two new ones

starting that month, and four more in the works. I had more to do than get back to "How are you?" BBS messages.

How am I? Don't ask. I already covered that a few months back in detail. I'm fine, thank you. Having been dieting lately, I'm even less tolerant of fools and their blather about no-code than usual. Not one single new argument, pro or con, has surfaced in the 32 years I've been championing a no-code license. Phooey.

Getting back to BBSs, I prefer to spend my time reading (for my education), writing (to educate others) and getting things done toward my goals in the music, educational, publishing and ham fields. All work? Nah. I do get out skiing, diving, watch some TV, catch a few movies, see some plays, and go to some concerts. Not bad for living in the mountains of New Hampshire, eh?

Old-timers have followed me from the *73* start in October 1960 in a little two-room office over a Brooklyn grocery store. Even older-timers remind me of my first ham magazine back in 1951, which I started from Cleveland, Ohio, while working as a TV director.

I've been giving advice for most of these 40 years. A few people have taken it and done well . . . getting into the hundreds of millions. Some have ignored it and lost . . . some have even lost billions ignoring my advice. I don't think anyone has ever lost by paying attention to my predictions.

Negative Vibes

Does your faith in amateur radio have the vitality to face unpleasant truths about your hobby? Or do you prefer the usual whitewash, everything-is-actually-peachy approach in your reading?

I get a few letters grumbling about my gloom and doom observations. It seems to escape these negative-oriented folk (of which we have a seemingly endless supply in amateur radio) that my glooms are always accompanied by creative, constructive solutions to our problems. I believe in facing our problems and solving them. That's the only way they're going to go away. I'm solution-oriented. How about you?

On a recent skiing trip to northern Vermont I finally had enough time to myself to get some work done. First, I planned a complete reorganization of the reporting system for the many projects I've got going.

Then I caught up with a cubit stack of magazines I'd brought along. I like to keep up with technology. I never know when I'll run across something which I can use. So I read *Scientific American*, *Omni*, *Discover*, *Fortune*, *Success*, *Technology Review*, *Kappan*, *Inc.*, etc., marking ideas of value as I go.

The magazines read, I turned to a stack of books. I always take along more than I can possibly read. The last time I went on a reading binge like this was a year ago when I was on a scuba diving cruise with Chuck KO1I. We dove all day and I read the rest of the time. This time I skied most of the day and read the rest of the time.

Now there you go, being negative again, grousing about old Wayne wandering off about this and that. Yes, I do, it's one of my few charms. But wait'll you find out what I lucked into, bookwise! One of 'em explained a lot to me . . . and you should find it interesting, too.

The book was "How to Work the Competition into the Ground and Have Fun Doing It," by John Molloy, the chap who wrote "Dress for Success" and "Live for Success," both of which I enjoyed. This little old $10 paperback was great! Full of ideas.

But the part that was of the most interest to me had to do with creativity. I'm always interested in this subject and how it can be taught. Well, John does a lot of consulting and one of his projects was to try and find out how creative people differ from others. And why.

Being an almost pathologically creative person . . . it's more of a curse than a gift . . . I wanted to find out how this happened to me. John interviewed a bunch of outstandingly creative people, trying to find out what they had in common. His findings were surprising . . . and discouraging.

I found them discouraging because I was hoping creativity might be more teachable. Entrepreneurs need creativity in heaps to surmount the constant flow of serious problems they face. America needs creativity if it's going to regain its lost high tech industries. We're famous for inventing new technologies and then watching the Japanese develop the practical applications, running creative circles around us.

We invented tape recording, and they smothered us in innovative tape recorders. We invented digital watches, and they buried us in innovative watches. We're desperately hurting for creativity in our industrial research labs.

Look at how we're hurting in amateur radio for the lack of creativity. We should be years ahead of where we are in spread spectrum development, in high speed digital communications . . . including not only words, but graphics and music. We've deplorably let our hobby and our country down. We're far busier fighting over that antique communications curiosity, the Morse code, than in trying to move ahead. Morse is fun, but it's about as relevant to communications today as the cat's whisker and a chunk of galena. It's for people who are holding desperately onto the past because they have no vision of the future.

I couldn't help but take another swipe at the old-timers who have dedicated their lives to trying to bury amateur radio . . . along with themselves.

Now, back to what John found out about creativity. We're talking creativity in business and engineering, not artists and poets. First, he found that creative people tended to be highly intelligent. Second, they were hard and effective workers. John says, "In fact many work all the time. They never turn off. They take their work with them wherever they go." Hmmm, that sounds familiar! Hey, that's me, with my laptop computer in the back seat of my van.

"They create by bringing order to seeming disorder. They're always thinking, rethinking, reviewing, and reordering." It's the old 5% inspiration and 95% perspiration formula espoused by Edison.

The third characteristic of creative people is a positive attitude. Oh, they are as aware of the problems as anyone, but they're optimistic about them. When I get a letter from a reader saying he doesn't always agree with my editorials, I know he's not a creative person. A creative person reads my editorials and comes up with even better solutions to problems. He just doesn't think in negative terms.

When I get a really negative letter I feel sorry for the writer. I know he's that way about everything and with everyone. He isn't selecting me to dump on, I'm just one more. What a horrible person to have to work or live with!

Molloy found that creative people were loners as children. They tend to march to their own drum and to heck with conformity. "Pragmatic nonconformists," Molloy calls 'em. Most still dress the way they want and don't care what others think. As kids they didn't have many friends . . . didn't need 'em.

I tried smoking and didn't like it, so I never smoked. I tried drinking while I was in the Navy. When I noticed that alcohol made me stupid, I stopped. I tried pot and LSD a couple times. Nope, not for me. I tested those drugs and decided conformity wasn't worth it to me.

Creative people love solving problems. Maybe that's why I can't pass up a crossword puzzle or a cryptogram. And I truly enjoy helping people solve problems. That's why I read over a hundred magazines a month and books by the dozen . . . I get Ideas from them which eventually click into place to help solve a problem. I enjoy mentoring college students.

Well, hooray for me. Yeah, I suppose. But understanding that negativeness prevents people from being creative is worth understanding . . particularly if you are an employer . . or if you're looking for breakthroughs in amateur radio. Employers need creative problem solvers, not negative thinkers. And they get hard workers as a bonus.

With the future obviously going electronic, we need all of the creative people we can find. And we need to attract 'em to amateur radio, where they'll be able to help both us and our country. If we let the Morse coders keep us In the 1930s, we're signing a death warrant for the hobby . . . and we could be helping to consign our country to second place . . . or even third, behind Europe.

Yes, I know all about the new no-code Tech thing. I also hear the old-timers' necks creaking as they warn of dire consequences. Meanwhile, the ham industry—in a burst of euphoria—is again expecting the money tree to start growing. Like when we got Novice Enhancement. Remember that beaut?

Being pragmatic, I warned that all we'd done is remove a small roadblock. We still hadn't put up any road signs. The no-code deal is another block gone. We still have to go out and advertise or the kids aren't going to even know our road exists. Has the industry learned yet? Are you kidding?

I'll be reading every ham club newsletter I can get to see if one ham club anywhere has come up with a positive program to promote the hobby to kids and get the parade started.

If I Asked You . . .

Suppose we're having a contact and I asked you to tell me about a time when you really had a lot of fun with amateur radio. What would you tell me? A question like that could keep me going for days. How about you? I don't suppose there's any chance you'd take a few minutes and write, since I haven't run into you on the air recently?

Ham radio has provided me with a couple lifetimes of fun. That's one of the main reasons I got snookered into publishing *73*. It's got something to do with wanting to share the things I've enjoyed with as many people as possible. In my *CD Review* magazine I'm having fun introducing the readers to music they might otherwise have missed.

When I got out of the Navy after World Misunderstanding II, it didn't take me long to build an all-band (813 s) kilowatt rig. Then I lucked into a beaut of a 75m kilowatt rig (203Zs). I had two complete kW stations, one with an SX-28 Hallicrafters receiver, the other with a National 100A.

I had my ham shack set up in the basement of my fraternity house at college, with antennas all over the place. The fun was to get into a round table on 75m and then go down to 20m and make a DX contact and rebroadcast his signal on 75m to the round table. In this way we were able to work African, European and Asian DX stations into our round table. The net could hear the DX chap through my 75m rig and he could hear the net through my 20m rig. That was a ball!

Yes, of course I got a pink ticket from an FCC monitoring station. I just sent 'em a copy of the letter I'd gotten from the FCC in Washington saying this kind of operation was legal. Didn't hear any more.

So tell me about some of the exciting things you've done. If you get me excited too, I might share your story with the *73* readers . . . or in a publication to help get Novices more involved with the hobby. Remember, when you're a silent key, about all that will live on after you is what you get published.

And it's really fun when your friends read your stories and feel they know someone famous. Or when someone you contact on the air has read your stories and recognizes your call.

I can handle anything I can read, from old notebook paper to a computer printout, but of course It's easiest for me if you include a floppy disk. 73

STS-35: Mission Accomplished!

It's been over seven years since the first ham-in-space activity by Owen Garriott W5LFL from the space shuttle *Columbia*. Since then, others have gone into orbit with amateur radio gear. Callsigns like WØORE, DPØSL and U2MIR have been heard from orbit. Now WA4SIR joins the ranks of the ham-in-space fraternity. His efforts from STS-35 were quite popular and very successful.

Columbia blasted skyward on December 2, 1990, in a spectacular nighttime launch carrying the Astro-1 telescope mission and Ron Parise WA4SIR with his ham radio gear.

The $150 million Astro STS-35 mission carried four advanced imaging systems. The broadband X-ray telescope, designed to be pointed by ground controllers, worked well. It succeeded in sensing much cosmic phenomena not visible from the Earth's surface due to the absorbing characteristics of the atmosphere.

The other three telescopes, aimed at their targets by computers in the shuttle, were designed to receive ultraviolet radiation. On the first day of the mission, one of the telescope-steering computers failed. Four days later, the second one went down. The systems were located in the shuttle rear-deck area. Ground crews and the flight team found the situation difficult, but not insurmountable, as controllers on Earth radioed target coordinates verbally to the astronauts, who used joysticks and TV cameras to aim the telescopes manually.

SAREX-II Successful

The Shuttle Amateur Radio EXperiment went much smoother than the telescope operations, but not without a few problems. On the positive side, 238 stations around the world managed to make complete two-way packet contacts with the WA4SIR ROBOT terminal node controller (TNC). Signals from the shuttle could be heard on 145.55 MHz FM. The corresponding uplink was 144.95 MHz. Note Table 1 for a comprehensive list of those logged as complete contacts.

A few stations even had two-way voice contacts with the shuttle. Several hundred more packet stations were heard by the SAREX-II system and received unique QSO serial numbers. However, they weren't able to complete a verified two-way exchange. Thousands of stations attempted to contact Ron without success, but it was educational and even entertaining just listening to the voice activity or watching the packets flash past as *Columbia* flew overhead. Table 2 is a sample of a SAREX-II bulletin sent on the second day of the mission, plus some other bits and pieces of packets received as the shuttle sped around the world.

Not all of the shuttle activity used the published 145.55 MHz downlink frequency. Conversations could be heard on nearby frequencies during many evening passes when the shuttle was within range of the Johnson Space Center in Houston, Texas, or the Goddard Space Center in Greenbelt, Maryland. Several phone patches were made for the astronauts with their families.

Although many hams were probably listening in, interference was rare and the conversations, at least from the shuttle side, could be monitored on small home systems or even HTs.

If you are on the gold-star QSL list in Table 1, or if you made it to the silver-star QRZ list (published by AMSAT), send your QSL to the ARRL, 225 Main Street, Newington CT 06111, Attention: Education Activities Department. A silver-star contact means that the robot heard your call but could not complete a two-way acknowledgment. QSLs are also available for SWL reports. Those few stations that had the pleasure of a two-way voice QSO will be eligible for the top-grade QSL reply.

An important part of Ron's activity from orbit involved schools around the U.S. Although the shuttle was not in view over the U.S. during school hours, methods were devised to connect Ron to a phone network via hams in areas of the world that had direct 2 meter access to the shuttle. Stations in Australia, including VK2AS, VK5AGR, and VK6IU, provided access during passes over their coverage areas while PY2BJO did the same from his location in Brazil.

Questions were uplinked to Ron via this system. Ron would answer the questions, many times adding commentary about the view from above, and giving updates on the Astro-1 experiments. While only a few schools were involved with direct communications with the shuttle, many others were online, listening. AMSAT and ARRL representatives were pleased with the results, considering the complexity of the arrangement.

Lessons Learned

There were many comments from the Monday-morning-quarterback point of view about the STS-35 SAREX-II operation. The ham-in-space activity was extremely successful. Not all hams made contact with the shuttle, but everyone who tried, should at least have heard Ron or the robot. Much of the difficulty in working the shuttle was caused by vehicle attitude, operator schedule, interference, and system limitations.

During the flight of STS-35, the shuttle had to align itself for telescope observations. Since the 2 meter antenna was located in either the pilot's or commander's window, much of the time it was aimed away from the earth, or, due to its directivity, it was aimed at only a portion of its potential coverage area. Because of the vehicle's orientation, not even an antenna in the cargo bay would have cured the problem on this flight, but it could help considerably on future missions.

Because of phone patches and private conversations, the packet system was not active on many passes over the U.S. If a second radio operating on 70cm could be employed for private voice activity, the packet system could be operated full-time on 2 meters. But the amateur radio experiment isn't a paying customer, and it's difficult to justify the inclusion of more ham equipment just to simplify packet connects to an orbiting robot system.

Congestion QRM

For hams in remote locations around the world, it was relatively easy to make a complete packet contact with the shuttle. In the U.S., the situation was quite different. With as many as a few thousand stations all sending packets on the primary uplink frequency of 144.95 MHz, it is likely the SAREX receiver was in a state of constant overload. The 60 stations in the continental U.S. that actually completed a full two-way contact with the robot were either running a lot of power at just the right time, or were incredibly lucky, or both. Also, many uninformed hams could be heard calling before the shuttle was above the horizon, after it was long gone or even on the wrong frequency.

Fortunately, the shuttle activity on 144.95 MHz caused little disruption of the DX packet cluster using that frequency for terrestrial DX information forwarding. If the shuttle activity had occurred during a DX contest weekend, there could have been significant disruption of packet clusters.

Since Owen Garriott's flight, congestion on 2 meters has increased. Ham-in-space SAREX operation has been infrequent and of short duration, but it will require more coordination when ham activity from a U.S. space station becomes a reality.

The robot could only support nine simultaneous connects in progress at any time. During a typical successful robot QSO, an Earthbound station sent a connect request skyward. The robot received it and sent an acknowledgment with QSO serial number establishing the complete connect. The Earth station then sent an ACK back to the robot which, upon receipt, logged the Earth station's call in the QSL list and initiated a disconnect packet.

Unfortunately, due to heavy crowding on the uplink, many stations could not get their ACK back to the shuttle after the connection had been established. The robot continued to hold their callsigns until the connection timed out, thus making it impossible for others, beyond the nine connected stations, to get in. Only 13 percent of those stations who managed to initiate contact with the robot completed the two-way exchange.

Table 1. Two-Way Packet Contacts with WA4SIR

What's Next?

The Soviet space station *MIR* has been active on 145.55 MHz FM simplex for quite some time. Musa U2MIR (UV3AM at home in Moscow) has been heard many times between 1200 and 1300 UTC. Mission Commander Victor U9MIR may also be on the air as time permits.

QSLs for current *MIR* contacts should be sent to: UA6HZ, Valery Agabekov, Box 1, 375600 Yessentuki, USSR.

Packet operation may begin this spring when the equipment can be sent up on a Soviet *Progress* launcher. The packet radio experiment acronym is AREMIR, for Austrian Amateur Radio Experiment on MIR, and consists of a TNC-2 and 2 meter HT built into a "black box" with connectors for the antenna and a laptop computer. Launch is anticipated in mid-March after some slips due to delays in final AREMIR checkout.

For the first few months AREMIR will operate in the beacon mode. Later, a laptop will be sent to *MIR* so the cosmonauts can enter messages. There is currently some concern about whether the laptop will survive environmental testing. It may not arrive at *MIR* until September or October, when the Austrian cosmonaut is scheduled to go to the space station.

STS-37 is currently scheduled to take off in early April. ALL of the astronauts are licensed hams! They include: Ken Cameron KB5AWP, Jay Apt N5QWL, Linda Godwin N5RAX, Steve Nagel N5RAW, and Jerry Ross (waiting for a new callsign).

The system they will take to orbit is comprised of a 2 meter HT, a spare battery, an interface module, a SAREX headset assembly, an equipment assembly cabinet, a TV camera with monitor, a laptop computer, and the window-mounted antenna. The equipment cabinet houses power supplies, a slow-scan TV unit, a fast-scan TV unit, a packet TNC, and the right connectors for hooking everything up.

While voice operation requires operator attendance, the other modes can be run either with or without someone at the controls. This promises to be an exciting mission. Check the AMSAT nets and bulletins for updates. 73

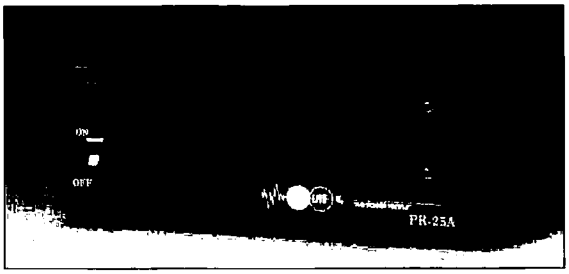
NEW PRODUCTS



PRODUCT OF THE MONTH

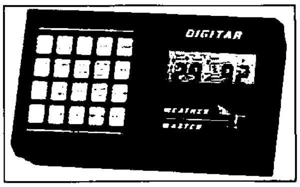
TRIPP LITE—PR-Series DC Power Supplies

Tripp Lite's new PR-Series DC power supplies are housed in a handsome dark metal cabinet that blends in with modern amateur radio and communications equipment, giving an integrated, professional appearance to any radio or electronics installation. Ideal for powering practically all types of 12 VDC equipment, the PR-Series combines good looks with exceptional performance for base or mobile radios, test equipment, and other electronic gear. Continuous-duty performance stands up to extended periods of reliable operation. These power supplies provide excellent IC voltage regulation, automatic overcurrent protection and full line-isolation.

The PR-Series DC Power Supplies are available in 3 to 60 amp sizes, with suggested retail prices starting at $38.50. For more information, contact *Tripp Lite, 500 N. Orleans, Chicago IL 60610-4188. Telephone: (312) 329-1777; FAX (312) 644-6505.* Or Circle Reader Service No. 201.

ELECTRON PROCESSING

Electron Processing is now offering a pair of high-quality keying devices. The Green Lake paddle and key are individually handcrafted by a master machinist and designed to withstand rigors and abuse that would destroy many other paddles. They are made of solid brass on a polished brass base (bakelite on the straight key), and they come with either hand-rubbed wood handles or polished aluminum handles. The Green Lake products are priced at $90 for the keyer paddle with wood handles, $100 with aluminum; $70 for the straight key with wood handle, $75 with aluminum. The S & H charge is $5. Electron Processing is also offering a new shortwave wire antenna, the Multiwire-4. For more information contact *Electron Processing, Inc., P.O. Box 68, Cedar MI 49621; (616) 228-7020.* Or circle Reader Service No. 204.



AZIMUTH COMMUNICATIONS

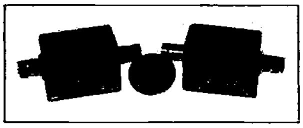
The new WeatherStar Master Weather Station ALT6 will help you monitor weather conditions with functions that give you barometric pressure (in. or mm), altitude, wind speed (MPH/KPH), wind gust record, wind direction (2 & 10 degree increments), daily and yearly rain (0.1" increments), an optional self-emptying rain gauge, inside temperature (with alarm), outside temperature (with alarm and min/max temperature record), wind chill factor, time of day (12/24 hour with alarm), and programmable scanning of functions. The ALT6 lets you set an alarm to warn of excessive wind gusts around your antennas and QTH.

The WeatherStar Master ALT6 is priced at $300, plus $7.50 for shipping. The optional self-emptying rain gauge (RG3) is $50. Contact *Azimuth Communications Corp., 3612 Alta Vista Ave., Santa Rosa CA 95409; (707) 577-8007, FAX (707) 573-1482.* Or circle Reader Service No. 206.

TIARE PUBLICATIONS

Tiare Publications has released a new *Great Radio Reads* catalog, #5. Now expanded to 20 pages, this catalog features nearly 30 Tiare books and products, as well as over 50 books and products from other publishers and manufacturers.

This new 5th edition of *Great Radio Reads* is available for $1 from *Tiare Publications, P.O. Box 493, Lake Geneva WI 53147; (414) 248-4845.* It is also enclosed free with all orders. Or circle Reader Service No. 208.



IDC COMMUNICATIONS

The WBA1500 from IDC Communications is a wideband mast-mounted RF preamplifier designed for use with wideband receivers, scanners, or even TVs and stereos, to improve performance and make up for long antenna cable runs. The WBA1500 covers 2 MHz through 1.5 GHz. A bench-type version, WBA1500B, is also available for frequency counters, oscilloscopes, spectrum analyzers, and related test equipment. The WBA1500 system comes complete with amplifier module, DC supply module, AC adapter, and BNC connectors ("F" type jacks are also available). The WBA1500 sells for $78, and the bench-top model for $57, postpaid. Contact *IDC Communications, 2745 Winnetka Ave. N., Suite 205A, New Hope MN 55427; (612) 888-7456.* Or circle Reader Service No. 205.

DELTA RESEARCH

DELTACOMM Version 1.04 from Delta Research is a state-of-the-art communication manager for the ICOM IC-R7000. Unlike similar products on the market that merely control the receiver, DELTACOMM 1.04 includes a custom MS-DOS interface for control, plus a comprehensive set of software communication tools to analyze, log and generate reports from the data. The spectrum log function can sweep a frequency spectrum at approximately 1300 channels/minute, generate a histogram, and log frequency/activity to the disk.

DELTACOMM 1.04 is priced at $300 (including external interface and components for cabling), plus $4 S & H. Contact *Delta Research, P.O. Box 13677, Wauwatosa WI 53213; (414) 353-4567.* Or circle Reader Service No. 203.

RUTLAND ARRAYS

Rutland Arrays has announced a new antenna, Model RA7-50. Model RA7-50 is a 7-element, 26'7" long, 50 MHz yagi antenna. It has a measured gain of 10.5 dB over a dipole, and matches the performance of other antennas measuring as much as 7' longer. The sidelobes have been lowered to 22 dB below the main lobe, and the F/B ratio is 30 dB at 50.2 MHz. The design features stainless steel element hardware, extruded aluminum element mounts, a T-match driven element with silver-plated, Teflon™-insulated phasing line, and 90+ MPH wind survival. A waterproof N-type coax connector is standard. For the price and more information, contact *Rutland Arrays, 1703 Warren St., New Cumberland PA 17070; (717) 774-5298 (7-10 p.m. EST).* Or circle Reader Service No. 207.

SPECTRUM INTERNATIONAL

Spectrum International is now importing and distributing a complete weather satellite receiving system, including a PC controller, from Time Step Electronics of Great Britain. Instead of using a downconverter from 1691 to 137 MHz, then feeding the signal into a 137 MHz receiver, the new 1691 MHz design uses a dedicated 1691 MHz receiver. The companion low noise GaAsFET preamplifier has increased gain and better filtering than earlier models. The new system also has a companion decoder board (IBM-PC compatible, short-slot "half-card") and software.

The 1691 MHz preamplifier is $175, the receiver is $450, and the decoder board with software is $300. For more information, contact *Spectrum International, P.O. Box 1084, Concord MA 01742; (508) 263-2145.* Or circle Reader Service No. 202.

T/R Controller to Drake

Picking up where we left off last month, we'll finish up the T/R controller. This month we'll look at how to interface the controller to the popular Drake R4B and/or R4C receivers. While we're working with the Drake receivers, we'll convert them over to cover all of the WARC bands. This is a simple modification consisting of nothing more than adding a crystal and peaking the front panel controls.

Of course, you don't have to have the Drake receivers to work with the T/R controller. But the following will give you a good idea of how to connect whatever station receiver you're using. The relays specified for the T/R controller need not be used. In the photographs of the final version, I use one onboard relay and a 4PDT relay mounted off the board. This relay does most of the work in my version.

Feel free to use whatever you have lying about in the junk box. Just keep in mind the coil current that you can sink with the two switching transistors. Also, you don't have to worry about adding a diode across the off-board relay's coil, since one is mounted on the board. If you choose to go with an external relay, just connect up the two pads used for the relay coil and run wires to the coil of the external relay.

Because the case I used for the T/R controller was not high enough for the relay I chose, I had to mount it sideways. I used a small piece of copper-clad PC board and a junk box nylon mount to accomplish this. I also spent the extra dollar on a socket to hold the relay. Mounting the relay on its side made wiring to the contacts very easy.

Speaker Mount

The sidetone generator requires a speaker, which I mounted on the bottom of the chassis. A small dap of Super Glue™ holds the speaker in place. After I did this, I thought the addition of some holes to allow the sound to come out of the chassis would be a good idea.

As a second thought, the speaker could be mounted upside down with some holes in the bottom of the chassis. This might make for a good sounding tone without creating a mess on the top of the chassis. I used a small 8 ohm speaker from the junk box. Radio Shack sells one for several dollars that will work fine.

Antenna Switching

As I mentioned last month, the antenna switching is done by another relay. I used a 12-volt junk box relay rated at 10 amps. This is more than enough for QRP use. I switch +12 volts to the relay. RCA jacks provide a quick and dirty way of supplying control voltage to the antenna switch relay. The +12 volts is supplied via the T/R controller.

For maximum flexibility in connecting up different rigs and transmitters, I also used two different types of connectors, RCA and SO-239, for the antenna and receiver/transmitter. The Drake receivers use RCA jacks for antenna input, so I use a cable with RCA plugs on both ends: one to the receiver, the other to the antenna switch. The main antenna terminates with a PL-239 that plugs into the proper SO-239 socket on the antenna relay.

Mute Confusion

The last and sometimes the most confusing connection required is the mute line. In the Drake receivers, the mute line must be grounded to operate the receiver, and open to mute the receiver. This switching is all done in the T/R controller. With the T/R relay, we have a choice of selecting ground or open muting, depending on how we wire the relay's contacts. A small shielded cable connects the T/R controller to the receiver. Since the Drake mute jack also terminates with an RCA jack, a suitable cable is used, RCA to RCA. I installed RCA plugs on the back of the controller for ALL functions.

The key-in line should be connected to your keyer/computer/straight key. To activate the T/R controller, you apply a ground to the key line. Since you're not switching heavy current or high voltage, you don't need to worry about damage to the keyer. Also, in the nasty and unlikely event the home-brew transmitter you're working on decides to short out its keying transistor, and feed +12 volts back through the key line, nothing will happen to your keyer. The T/R controller fully isolates the key output from the key input.

A simple block diagram may help with the interconnection. Use this only as a guide; nothing is carved in stone!

I've never been much of a receiver builder. As was the case when I started working on the T/R controller, I never could seem to get a home-brewed receiver to work as well as a commercially built one. But I wanted a really good receiver, one that'd allow me to listen in on the WARC bands. So what I ended up with was a Drake R4B. This receiver is not new by any means. It dates back about 15 years or so when real radios glowed in the dark. Yes, the ol' Drake has tubes in it. It also has one more thing of great importance: additional tuning ranges.

By inserting the appropriate crystals in the accessory crystal sockets at the rear of the chassis, it is possible to add up to 10 additional tuning ranges. Each of these is 500 kHz wide, except for the 5.0 to 6.0 MHz band. This is the Drake's frequency for the VFO. Anything else is fair game! I installed crystals for 28.000 to 28.500 MHz, 18.068 to 18.168 MHz, 24.890 to 24.990 MHz, 10.100 to 10.150 MHz, and several for shortwave listening.

The extra crystals are installed in the rear apron of the Drake. I ordered the crystals from Jan Crystals in Florida. Just have the frequency of the rocks you need, and they'll do the rest. In a week or two you'll get the crystals. This is the type of modification I like the best. Order the crystals, install them, and start working the new bands. I made up a cheat sheet to allow quick tune-up of the new bands, because the Drake will resonate the newly installed bands under different settings than one would think. For example, the 30 meter band requires the band switch setting to be on 14 MHz, while the preselector is at the 40 meter location.

That's about all there is to getting the Drake running on the WARC bands. There's a lot of life left in those receivers, and as the old saying goes, "You can't work 'em if you can't hear 'em." 73

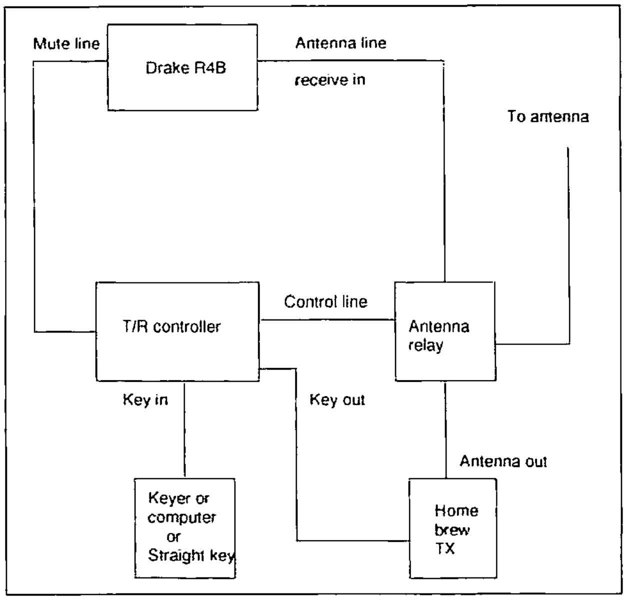

Figure. Block diagram of the interconnections for the T/R controller.

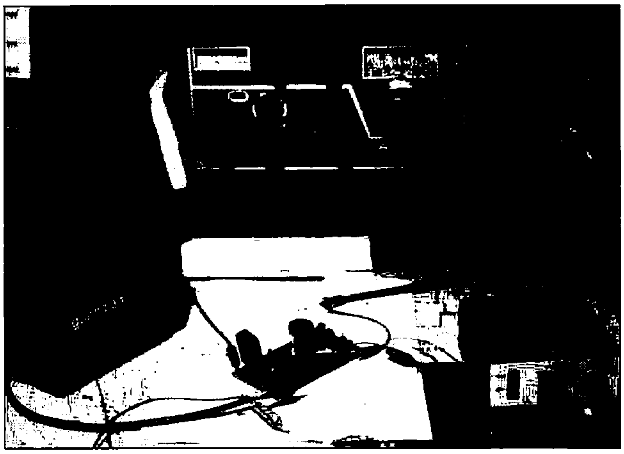

Photo A. A home-brew CW transmitter, solar-charged battery, and the Drake R4B receiver: QRP heaven!

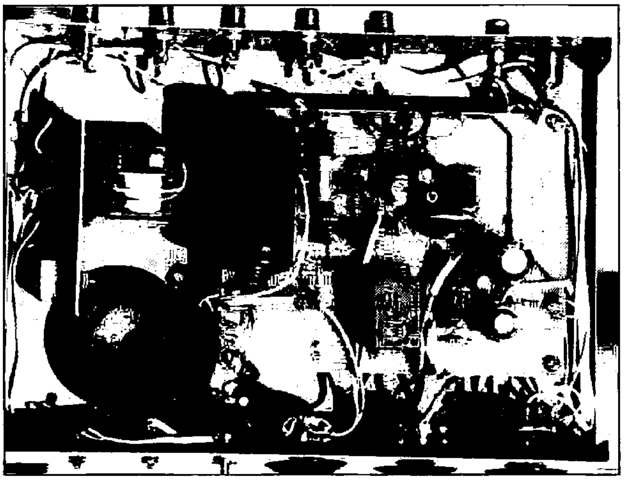

Photo B. Inside view of the T/R controller. Notice the relay mounted off of the board next to the speaker. There is one relay mounted on the board in this version of the controller.

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Microwave Beacons

To round out last month's column on waveguide mixers and microwave formulas, this month I'll cover a typical 10 GHz microwave beacon. By changing the RF source and antenna, you can adapt the plans for this beacon to other microwave frequencies.

Unlike beacons on lower frequencies such as 6 meters, microwave beacons are not put up only to reveal current propagation conditions. If you heard a 6 meter beacon clearly, you would rush to the shack and start operating, looking for contacts on that band. But if you heard a microwave beacon from some remote location, you would, instead, get busy on the phone to set up contacts.

The microwave beacon not only alerts you to band conditions, but also serves as a piece of test equipment. During contests, the microwave beacon transmits a signal that stations can use to check antenna alignment and to prove that their stations are functioning normally. Most importantly, the microwave beacon provides a reference signal local amateurs can use as a transfer frequency standard. This way, the custodian of the beacon can verify frequency as accurately as he can (in the band, of course) and set the standard.

Frequency and Offset

In any large group, someone can come up with a best method of determining frequency either by wavemeter or frequency meter. The method used doesn't make any difference. When you have this type of system in place, all other stations can set their equipment to copy the beacon. You can set your system's frequency to either sideband mix product, offset by your IF frequency. This offset is determined by whatever IF frequency you are using. One standard is 30 MHz. For example, if the transmitter is on 10.250 GHz, you can copy on either 10.220 or 10.280 GHz, since both frequencies are in the 30 MHz offset due to the IF frequency.

When all local stations are copying the same beacon, frequency determination problems decrease. Until most amateurs in an area can agree on just where 10.250 GHz is, it can be a large stumbling block. Even if a beacon is slightly off-frequency, everyone in the local area using the beacon will be affected the same. What matters is that all stations in a local area know where the beacon is and use it.

Antenna Checking

With a microwave beacon, you can check your antenna direction pointing, and test the sensitivity of your receive system. Microwave antennas, especially dish types, can have beam widths of 3 to 4 degrees or less. This makes accurate dish aiming very important. Copying a local beacon, you can verify direction (compass bearing) and vertical position. This helps eliminate one more wobble in the system. Sensitivity can be verified by comparing results to past tests, or by placing an attenuator in the system for further tests. Use of a beacon has proved to be a valuable asset, letting you make quick assessments of system performance. Quick verification can be everything during contest weekend. See the beacon schematic in Figure 1.

The Beacon System

Construction of a 10 GHz beacon is quite simple. All you need is a source of RF, such as a Gunn oscillator, an identification system, and an antenna. The CW identification system, described in the June 1990 column, is just a simple TTL keyer with an EPROM loaded with your callsign. The unit repeats what is loaded into the EPROM over and over again, resettling after each message. The audio output from the keyer is coupled to the adjust terminal of a Gunn oscillator power supply, imposing wideband FM modulation on the Gunn oscillator.

In most beacon setups the power supply (unregulated DC) is remote to the actual beacon, with the Gunn oscillator/power supply modulator and keyer located within a common housing with the microwave antenna. The keyer is about the size of a pack of cigarettes and the Gunn oscillator is a compact structure about an inch and a half square. A short section of plastic drainage pipe is often used to house the entire system.

The Beacon Antenna

The antenna selected for beacon operation must be compact, high-gain, and omnidirectional to be of general use. What fills the bill is the near omnidirectional waveguide slot antenna. For 10 GHz, a waveguide slot antenna is less than a foot long; 6 slots (on each side of the waveguide) exhibits 10 dB gain. See Figure 3 for construction details.

The top of the antenna is shorted with a machined brass insert that closes off the top of the waveguide. A single waveguide flange connects the antenna. The Gunn oscillator may be directly connected to the antenna, or a magnetic isolator may be placed between the antenna and the Gunn oscillator. The isolator helps reduce pulling on the Gunn oscillator by allowing RF to flow freely in one direction, which provides high loss to reflected RF (VSWR).

The slots in the waveguide are vertical, in the same plane as the length of the waveguide. The radiated RF is *horizontally* polarized. To receive horizontally polarized radiation, your receive waveguide must be vertical (the longer opening of the waveguide). Having your waveguide *vertically* polarized means having the long opening of the waveguide horizontal. If this sounds confusing, just remember the rule: The

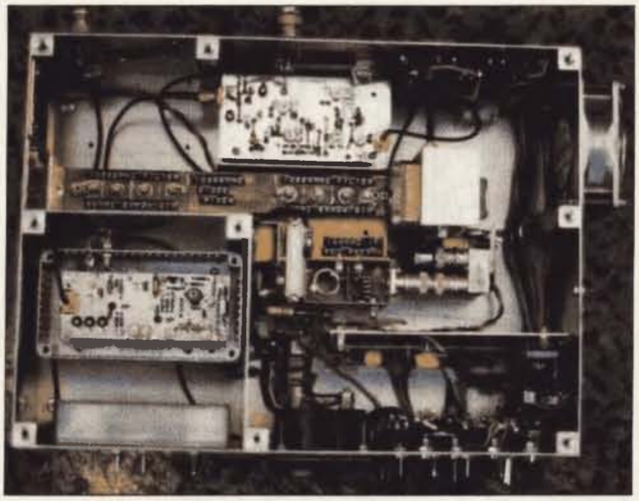

Photo B. "All mode" (CW, SSB, and NBFM) 10 GHz transverter constructed by VK2ALU. Oscillator chain and amplifier is a G4DDK design feeding a X9 SRD (step recovery diode) multiplier. The 10 GHz mixer section is a G3JVL design (image reject mixer) with output on 144 MHz.

Photo A. Lyle Patison VK2ALU of Wollongong, Australia, operating a 10368 MHz transceiver on SSB, testing over 80 km to VK2ZAC (who can receive on SSB but only transmit on NBFM). Note sighting telescope mounted below dish. A Cassegrain subreflector feed is used allowing more efficient illumination. The 20 inch dish is a searchlight reflector.

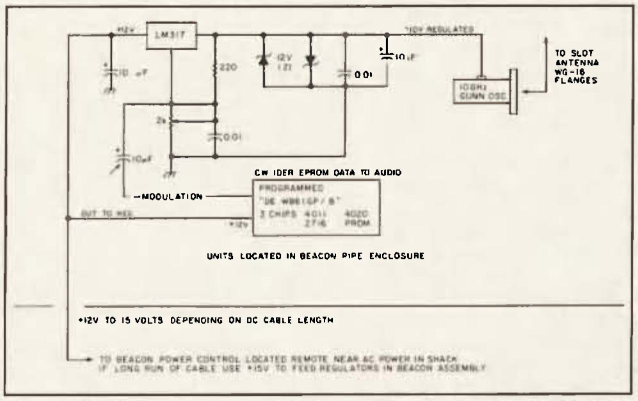

Figure 1. 10 GHz beacon showing CW ID'er and power supply. Regulator/modulator audio from ID'er feeds to adjust terminal of regulator for modulation on input on regulator output voltage to Gunn oscillator, which produces high quality wideband FM on 10 GHz (See "Above and Beyond" in the June 1990 issue of 73 for CW ID details).

polarization is opposite to the long opening of the waveguide.

If you try to copy a signal of the opposite polarization to what you're running, this will add an additional *30 dB loss*—yes, 30 dB loss—on your end of the circuit. This really makes it difficult to copy signals. Rotating the waveguide or system 90 degrees will help.

Mounting the System

The keyer, Gunn oscillator, and slot antenna are mounted inside a short section of 4" O.D. plastic drainage pipe with top and bottom cap plugs, available at most hardware stores, to waterproof the assembly. DC power is supplied via the cable to the regulator assembly located in the pipe. We usually provide 12 volts at the power supply and regulate the Gunn DC to 10 volts, and the keyer to 5 volts. DC loss is not a problem for moderate lengths of cable; for longer lengths, use 15 volts DC. See Figure 4.

Three beacons have been operating in the San Diego area for at least several years. Maintaining these beacons are Jack N6XQ, at his home on Point Loma overlooking the Pacific; Ed W6OYJ, at his home in University City just north of San Diego proper; and Kerry N6IZW, on Mt. Helix. The latter has served many hams for the years it has been in operation. All have proven valuable tools for microwave use.

Alternate Test Source

If you do not have a beacon or a signal generator in your area, for simple tests you can use the "boomerang," a test oscillator connected to the waveguide detector for the band of interest (10 GHz in this case). You must be using wideband FM and an IF system like the TDA-7000 IF amplifier ("10 GHz Fun," in the April 1990 issue of *73*) which has an IF amp operating at 30 MHz. It's easy to build. All you need is a crystal oscillator at 30 MHz coupled into the detector mount. Don't forget to provide a DC return (RFC) for the detector diode.

When the boomerang receives RF (from the transmit unit), it mixes the received RF with the 30 MHz oscillator and produces a return signal plus and minus 30 MHz back to the transmitter. This signal is not frequency dependent; it will work with any IF (change the crystal to your IF frequency). Also, it does not matter what your 10 GHz frequency is. In this regard, it is very poor to useless for frequency determination, but it gives a low level signal for testing.

Mailbox Comments

Junji Tamura JH1MOY of Japan is gathering components for a 10.475 GHz system. I must admit I do not know the band structure for Japan, but I am looking into this to find out which frequency the activity there is centered on. I hope to have more information on Junji's progress and other microwave activities from Japan.

Ammar Talhouni of Jordan writes that he is finding the microwave articles very interesting, but he is having trouble obtaining materials to construct the Polaplexer mixer and finding a source of Gunn diodes. He would appreciate any assistance. Well, Ammar, I would be glad to provide parts for the Polaplexer. The only additional charge would be for overseas airmail.

Shipping components to any part of the U.S. or Canada isn't a problem, but restrictions on exports to some countries might apply. According to the U.S. Export Administration, items such as Gunn diodes were restricted under tariff ECCN 1544A subpart b,1, but this restriction has recently been lifted. This makes shipment easier, as it now comes under the "general destination" category instead of "controlled tariff."

Kurt AL7LQ/3, a member of the U.S. Coast Guard, reports that he has moved from Kodiak Island, Alaska, to Laurel, Maryland. I know this will add some microwave activity to that part of the woods. Kurt is looking for information on an 11 GHz phase-locked brick manufactured by Micromega, and also for any information on a Huggins Labs TWT power supply model 328D. If you can help him out, write Kurt at 11658 S. Laurel Dr., #2 D, Laurel MD 20708.

Lyle Patison VK2ALU of Wollongong, Australia, writes about 10 GHz operation Down Under. He says it's difficult to obtain microwave components there. Despite this, he used a transformer he got from a microwave oven to construct a 1-watt TWT power supply for a surplus tube. Lyle states that this arrangement works well, but it's not too portable. I have to take my hat off to Lyle, as building a TWT power supply is no small undertaking. It's one that I (with all the components I have available) won't consider.

Lyle says there are two other amateurs in Wollongong on 10 GHz, one on SSB and the other on FM. There are two other SSB amateurs in Sidney, but Lyle says he has a 45 degree elevation rise in their direction, and has to use scatter propagation to make the 60 to 70 km path. See Photos A and B, showing Lyle and his very well-built, home-constructed equipment. His accomplishments are amazing—and in a location where microwave items are scarce. Keep up the good work, Lyle.

Kits and Parts

All kits and Gunn devices that I have mentioned in previous columns are still available at the same prices. Got to hold the line and keep things inexpensive. The only item that has proven difficult to get parts for is the ferrite antenna for VLF frequency calibration.

Add to this list of items the 10 GHz slot antenna described in this column. I have had them fully machined and constructed for those who do not wish to do it themselves from the instructions in Figure 4. The cost of the machined waveguide assembly, end cap, and high quality, commercially gold-plated waveguide flange, is $40 postpaid U.S. The antenna, as machined, exhibits an SWR of less than 1.1:1, about 32 dB return loss. The antenna assembly can be soft-soldered or brazed together in a few minutes. All three parts are a tight fit for final assembly. The flanges included in this kit cost just under $8 each, which was quite a shock to my system. Thought they should run about $4 for new flanges; boy, was my estimate in error.

As always, I will be glad to answer any questions relating to microwave or other topics. Please send an SASE for prompt reply. Chuck WB6IGP.

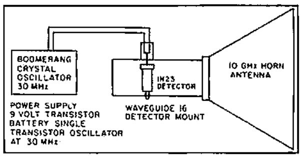

Figure 2. The boomerang. The microwave return signal test adapter receives 10 GHz RF and mixes with 30 MHz. Local oscillator and return microwave RF USB and LSB mix at 30 MHz spacing for receiver testing and antenna aiming tests.

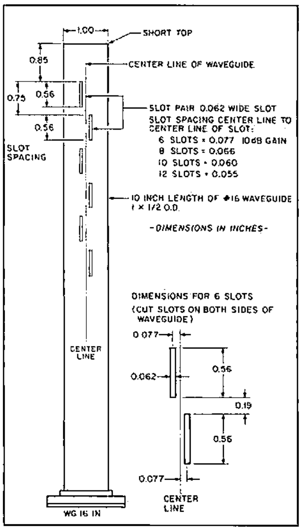

Figure 3. 10 GHz omnidirectional slot antenna, horizontally polarized with approximately 10 dB gain. Use a 10 inch length of #16 waveguide (1" x ½" O.D.) for the 6 slot version. Cut the slots into the 1" wide side of the waveguide, then flip it over 180 degrees and cut slots into the other side to match the slots you just cut out.

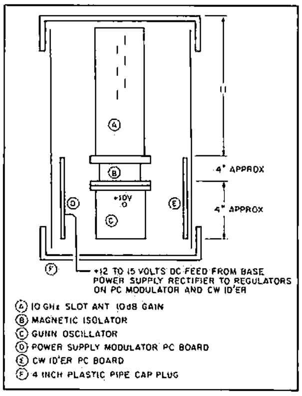

Figure 4. 10 GHz beacon system package. The waterproof DC cable exits from unit at the bottom. Attach a clamp to secure it. Do not place objects near the top of the antenna.

CIRCUITS

Great Ideas From Our Readers

The Versatile 7490 IC

The 7490 (74LS90, etc.) is specified as a decade counter, dividing TTL pulses by a factor of 10. What is not so well known is that this chip can be connected to divide by any whole number between 5 and 10. This lets you use cheap surplus crystals when building a crystal calibrator—secondary frequency standard—which should be in every ham station.

Because published circuits and commercial crystal calibrators use 100 kHz, or 1, 2, or 4 MHz crystals, dealers price these crystals higher than other surplus crystals. Using a 50¢ 7490 IC following any crystal oscillator using a 5, 6, 7, 8, 9 or 10 MHz crystal, output at 1 MHz is produced by properly wiring the 7490. This can be divided further if you wish, using a combination of dual flip-flop 7474s to produce the more usual 100, 50, 25 and 10 kHz marker frequencies (see "An HF/VHF/UHF Marker Generator," *73*, January 1991, p.27). The figure shows the connections which allow the 7490 to divide by 5, 6, 7, 8, 9 and 10.

Space—The Final Frontier

A classroom visit from Captain James T. Kirk of the *Starship Enterprise* could not have generated more excitement than the radio contact with two real-life astronauts that we had recently.

In early October, I was planning my strategy for introducing a unit on "Space Travel and Communications." I incorporate a major area on space in my ham radio curriculum every term. There is such an abundance of material that I've never taught it the same way twice in more than 10 years. This is a favorite area of study for my 6th, 7th, and 8th graders.

I finally decided that a great opening lesson would be to show an old science fiction movie from the 1950s and compare it to the tapes of shuttle launches and the SAREX tape from the ARRL. Purely by coincidence, when I opened up a session of the CQ All Schools Net, Jay Apt N5QWL was my first check-in. Jay introduced himself as an astronaut from the Johnson Space Center. He had heard about our net with schools across the country, and he wanted to get on and chat with the youngsters. I'm not sure who was more excited—the students or the teacher—but I do know that there was a smile on everyone's face that afternoon.

Jay spoke to the children about plans for future shuttle missions, and about how much he was enjoying ham radio himself. He made a big impression on the youngsters by telling them about the Importance of getting a good education and of considering technical careers. There was electricity in the air! Within minutes of the end of the contact, the rest of the school knew about our good fortune.

For days after the contact, parents contacted me to verify that it was all true, and to find out what we were doing in the ham radio program. What an incredible kickoff to my unit on space communications!

During the next four weeks, the children produced some of the most creative and well-researched reports and projects I have ever seen. Even the more "reluctant learners" came through with flying colors as they presented puppet shows with pipe cleaner astronauts and popsicle-stick space stations.

In the midst of this flurry of space-related activity, on November 13, John WD5EEV, our friend from the Johnson Space Center, checked into the CQ All Schools Net with a special guest. He cryptically told us "This will make your day." He was right! Next at the mike was Ron Parise WA4SIR, to say hello to the children. Once again, the excited looks of delight from the youngsters were a sight to behold. Ron told the class that the crew from the SAREX mission STS-35 was at the Johnson Space Center in preparation for the December launch of the *Columbia*. He also stressed the importance of getting a good education and encouraged the kids to think about entering technical fields of study.

I was privileged to observe the intense looks of pleasure on the faces of the children as they listened to the comments of a man about to go on a space voyage. It occurred to me that the astronauts are the real heroes of our times. The men and women who risk their lives and dedicate themselves to the expansion of scientific knowledge are the ones who are truly worthy of our respect and admiration.

While it may be true that you can't initiate every space unit with a live contact from an astronaut, there are countless high-motivational lessons that can be used to spark the children's imaginations.

The following are a couple of sample lesson plans. If any teacher is interested in getting copies of other space lesson plans, just drop me a line and I'll be happy to mail them to you. Please let me know about creative and successful lessons you are doing with your classes.

Lesson Plan—Shuttle Travel

Lesson Aim: To learn about space shuttle travel.

Motivation: Have students put up space shuttle posters in the room. Ask them to bring video tapes of launches that they taped at home from the TV news. Show the videotape "Space Camp," the ARRL videotape "SAREX," and other related tapes. Point out the role of communications in space travel.

Background: The U.S. space shuttle, the world's first reusable spacecraft, first flew in 1981. After reaching orbit, its two solid fuel booster rockets are jettisoned and then recovered. Its main fuel tank is released when empty; it burns up on re-entering the earth's atmosphere. The orbiter craft—the heart of the space shuttle—looks and lands like an airplane minus the engine. Special heat-resistant ceramic tiles protect it from burning up on re-entry. There are three orbiters in the U.S. shuttle fleet. The shuttle's cargo bay can carry satellites, scientific equipment, or a complete space lab.

Activities, Science or History: Have students research and report on Sputnik 1, the first satellite to orbit the Earth, or any other mission since then. Have committees report benefits to us from missions, such as international communications and TV links via satellite; weather satellites aiding in weather predictions used by farmers, sailors, and airlines; and even hams getting a chance to talk to astronauts while in space!

Activities, Language Arts: After viewing videotapes, elicit responses on what it would feel like to be launched into space. List words on the board appropriate to age level: dizzy, euphoric, light-headed, amazing, unreal, awesome, and so on. Discuss each word and have students write a paragraph describing how they'd feel during lift-off. Have students write a science fiction story about astronauts "lost in space" without their radios.

Lesson Plan for Spacelab

Lesson Aim: To learn about Spacelab missions.

Motivation: Say to students: "Imagine factory workers reporting to work in space. Does this sound far-fetched? Maybe not."

Background: November 1983, the space shuttle *Columbia* was launched with Spacelab 1 in its cargo bay. Spacelab was designed as a place where scientists could do experiments in the unique environment of Earth orbit. Due to weightlessness conditions in Spacelab, handrails and foot restraints were installed to prevent scientists from floating about.

Spacelab has a pallet (storage platform) where materials and equipment can be exposed to space and remotely handled by the shuttle's manipulator arm. The first Spacelab mission lasted 10 days.

Activities, Science or History: Have committees research the benefits derived from Spacelab missions: Group 1), animal research; Group 2), electronics/communications; and Group 3), drugs/medicines. Examples: 1) manufacturing silicon chips (used in computers) could be performed more accurately and economically in space; 2) conditions in space make drug-manufacturing easier; and 3) electrophoresis, using an electrical current to separate materials dissolved in a liquid, can be done with a greater degree of purity in space.

Activities, Art or Language Arts: Have students submit sketches of what a space "floating factory" might look like, then describe it. Have them write a composition telling what kind of people could work there. Describe what it would be like to live in the Spacelab for several months. One thing workers could do during nonwork hours (if they got their amateur license before the mission) is talk to family and friends on Earth by making contacts via amateur radio. 73

Cross-country ATV Adventure!

On a clear morning this spring, the door to a large blimp hangar in Orange County, California, will open to reveal a 75-foot diameter balloon, a gondola suspended high in the air just below the balloon, and a large ballast balloon on the bottom (see Photo A). Three daring balloonists will ride in the gondola as they attempt a nonstop cross-country flight.

This is a warm-up flight for their nonstop round-the-world flight scheduled for this November. Dubbed *Earthwinds*, the November flight will fly in the jet stream at a constant altitude of 35,000 feet. The three balloonists will ride in a special pressured gondola (see Photo B) suspended between the helium balloon and a unique ballast balloon. The ballast balloon is what makes the mission possible. Its weight can be adjusted by varying its internal pressure through means of a high-pressure fan and release valve. This means that very little ballast needs to be carried, resulting in very long flight duration capabilities. If the winds are favorable, it should take from 11 to 20 days to circle the globe.

Onboard the gondola in November will be captain Larry Newman KB7JGM, Maj. Gen. Vladimir Dzhanibekov (director of cosmonaut training in the Soviet Union), and Richard Branson (who just completed the first hot-air balloon crossing of the Pacific—Newman was the first to cross the Pacific in a helium balloon in 1981).

Since flying with the historic transoceanic balloon crossings of Double-Eagle II (Atlantic) and Double-Eagle V (Pacific), Larry Newman has dreamed of the ultimate ballooning conquest of a nonstop round-the-world flight. After years of planning, it could be a reality this spring.

Work a Balloon

Larry KB7JGM, a very enthusiastic ham, is quite active on 10 meter SSB (recently he's been found around 28.385 MHz). He is a pilot with America West Airlines (see Photo C), and soon plans to operate on 20 and 15 meters while on his twice weekly coast-to-coast Boeing 757 flights.

During this spring's balloon test flight, he will be active on 20, 15 and 10 meters. Listen on 28.385, 21.385 and 14.330 MHz for KB7JGM/balloon throughout the flight. When Larry is not operating live from the balloon, he may have a talking-voice beacon operating on 28.385 MHz to relay their altitude and position. Hopefully schools nationwide can monitor these transmissions and plot the balloon's path as it drifts across the country.

Live ATV from 17,500 Feet

In addition to Larry's HF activities, he plans to operate a complete ATV station! A live color camera attached to the railing of the gondola can be remotely pointed via a 2 meter control link when Larry is busy with other activities. When Larry is not receiving ATV, he'll be transmitting spectacular views of the Earth below that can be seen on 434 MHz (439.25 MHz alternate). Those of you with cable-ready TVs or VCRs can tune in on cable channels 59 or 60 (as long as you connect an outside antenna). Since they plan on flying at 17,500 feet for the cross-country effort, anyone within 160 miles of the flight path should be able to view the ATV signal or contact Larry on 2 meters. He will be monitoring 144.34 MHz FM as well as the HF frequencies.

Photo A. Earthwinds *test flight (Sept. 8, 1990) at 17,500 feet over Mt. Rainier, Washington. The March test flight balloon is identical to this system. Photo by Mark Greenberg/Visions.*

Larry can operate with either vertical or horizontal polarization on ATV. During each night, there is the possibility of a cross-band ATV repeater mode: 434 MHz input/1255 MHz output (AM or FM).

Two lines of telemetry will be displayed at the bottom of the screen showing the altitude, latitude, and longitude; and the temperature, ground speed, and heading. This is accomplished with the aid of a Magellan GPS (Global Positioning Satellite) receiver interfaced to flight computer/video overlay board available from High Technology Flight. The telemetry overlay system was designed by Bob Rau N8IYD and is similar to that used in previous balloon experiments (see High Altitude Ballooning, Photo E in the August 90 issue of *73*). *For more information contact Bob Rau N8IYD, 1450 Jeffery St., Ypsilanti MI 48198-6319. Telephone: (313) 482-2670*

Photo B. Pressurized gondola which will be used for the round-the-world flight at 35,000 feet this November. Artist rendering by Stan Stokes.

Flight Path

Typical spring wind patterns could take the crew along a path across southern California, Arizona, New Mexico, Kansas, Iowa, Illinois, Indiana, Ohio, Pennsylvania and into New York state. The flight could take between 2 to 4 days to complete. Keep in mind that this is only an estimate of the actual flight path. A few days before launch, the actual flight path should be easier to predict.

Due to the current world situation, plans for this spring's flight could change. Listen to the AMSAT nets, the ATV net (3.871 MHz, tues. at 8 p.m. EST) and packet BBSs, for updates.

Photo C. Larry Newman KB7JGM, America West Airlines 757 captain, and captain of the Earthwinds *balloon. Photo courtesy of America West Airlines.*

Photo D. With an ATV receiver you'll be able to see spectacular views such as this one. Don Moses (backup crewmember for the Earthwinds *flight) is dressed in his cold weather gear near the radio operating position. Test balloon at 17,500 feet over Mt. Rainier, Washington (immediate background). You can see Mt. Adams, Mt. Hood, and Mt. St. Helens in the distance. Photo by Larry Newman KB7JGM.*

Desert Voices

Continued from page 18

case another message comes through, and not bother with seeking publicity. The gratitude and recognition of the people you help may be enough for you personally. But no publicity means the larger community remains ignorant of what you're are doing.

In fact, many people have only a vague idea of what a ham is or does, and some may wonder if there is such a thing as a ham anymore. For example, in the first 38 years of my life, lived in five different parts of the country, I only met ONE ham. Though I knew him for 10 years, I didn't know he was a ham until I moved a couple of thousand miles away and began working for 73 *Magazine—and received a letter from him! Hams love to tune in the world on the air—but they forget to tell the world in person.*

Young people are especially affected by this lack of an image for the amateur radio operator. If they have never heard about amateur radio or met a ham, they cannot easily picture them in their minds. Yet young recruits are what amateur radio needs most of all. So, do it: Tell the world. 73

To send a message through Desert Voices to a loved one in the Middle East: First, please write for the proper forms. Address your request to: *Desert Voices Project, POB 23057, Minneapolis MN 55423.* Please do not call on the telephone unless it is absolutely necessary. If it is truly an emergency, and you *must* call to order a form, the number is (612) 463-7202. The office staff is not large enough to handle many incoming calls, and they would not like to have the line blocked.

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. You may also upload a listing as E-mail to Sysop to the 73 BBS /Hamhelp SIG. (2400 baud, 8 data bits, no parity, 1 stop bit. (603) 525-4438). Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. Thank you for your cooperation.

I need a schematic for ICOM-726. Mine was destroyed by a pet. Also, i would like to correspond with someone interfacing a Tandy Model 100 with the GLB-PK1L TNC. *Rick Thompson NØHKE, 2079 111th Lane, Coon Rapids MN 55433.*

Does anyone know where I can get a copy of a book called "The Ten Meter FM Hand Book," by Bob Heil? It's been out of print for about five years. I will pay copying charges for this book. *Bret Singer N3IHM, PO Box 1015, East Stroudsburg PA 18301.*

I need a schematic diagram for a Randix stereo cassette receiver, Model #SCR-7104. If you have a mailing address for the Randix Company, please mail the address to me. *Mr. John Sprenkle, 630 Cherokee Ave., Melbourne FL 32935.*

I have a young son with Down's Syndrome, and I would like to increase his speech ability using a speech synthesizer. Has anyone tried to interface Texas Instrument's French Speak & Spell to a computer? I would like to know how to go about making such a modification. I already have the schematic diagram for the Speak & Spell. Or would anyone know of a French speech synthesiser at an affordable price? Thank you. *Gregory McKenna VE2AGY, 33 Marcel, Valleyfield, Quebec, Canada J6S 4M4.*

I just bought a Tandy TRS-80 Model 4D, and cannot find amateur radio related software. I would appreciate copies of Public Domain or Shareware programs. I will pay postage and expenses. *Ibrahim Picard N5LYP, 501 Hudson Drive, Westlake LA 70669.*

I have a Telequipment Model S54A, 10x6 cm display, oscilloscope. The unit has no trace and I need a schematic and/or manual (even an address of the company) in order to complete the repairs. *Steve Reese KE8KF, N11.152 HWY M-95, Channing MI 49815.*

I have a Johnson Viking Invader 2000 6-band transmitter, without a power supply. I need a schematic and/or manual (or address of the company) in order to complete the repairs and build a power supply. *Steve Reese KE8KF, N11.152 HWY M-95, Channing MI 49815.*

Wanted: Instruction book for a Regency Whamo 10 scanner, Model ACT-W10. *R. Fuechsel, 12 Cove Lane Rd., Whippany NJ 07981. (201) 887-4034, evenings.*

I'd like to get in touch with someone who has a manual for a Cushman Electronics Model CE-4B Service Monitor. I'm trying to repair one and I need a copy of the service manual. I will either reimburse you for your copying and postage expenses, or you can mail me the manual and I'll copy and return it. Thanks! *Peter Simpson KA1AXY, 12 Ruthellen Rd., Holliston MA 01746. (508) 429-7069 (home) or (508) 870-9837 (work).*

Wanted: Collins R390 receiver service manual. *Lionel L. Sharp VK4NS, 19 Kelso St., Chermside, Brisbane, Queensland 4032, Australia.*

I need an operating manual and schematic for a Regency HR-2B transceiver. Will pay for copying and mailing. *Doug Stubbs, 69 Goff Rd., Lot 20, Corning NY 14830.*

I would like to obtain any mods available for the Bearcat BC760XLT, particularly increased audio and cellular phone info. *Chuck Kilch, 6083 Deer Run, Middletown OH 45044. (513) 890-7700.*

Wanted: Schematic diagrams for the Yaesu MH-12 speaker/microphone, Heath HW-2 2 meter handheld transceiver. *Glenn Torres KB5AYO, Rt. 1 Box 580-B, Reserve LA 70084.*

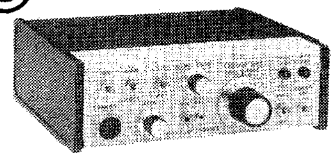
Wanted (desperately): DG-5 digital display for mint TS-520. I also need DK-520 kit for installation. I will pay top dollar. *Roger W7LJD, 1690 Allison Rd., Piney Flats TN 37686. (615) 538-8787 (call collect).*

Wanted: Schematic and manual for EICO 753 SSB transceiver. Will pay expenses. *Thomas McWilliams KI4N, 2600 N. Glebe Rd., Arlington VA 22207.*

I'm looking for a software program for the Commodore 64, to run an AMTOR BBS. *Howard Bacon, 213 Holly Ave. So., Pittsburg TN 37380-1313.*

AMATEUR TELEVISION

SMILE! YOU'RE ON TV



Only
$329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

How to Break Your Radio

In previous columns, we've explored many aspects of equipment repair, from setting up your shop to an overview of the diagnostic process, to the details of stage-by-stage repair. In each case, though, we've assumed nothing about the rig's history up to the point of repair. Often, that's a good approach, because you just may not know why the thing failed. If you do know, though, that information can provide very valuable clues which can save you lots of time and effort. So, this month we're going to look at ways you can break your rig, and what to look for afterward.

Oops...

Here, hold this while I...whoops, CRASH! And that new rig lies crumpled at your feet.

Yes, dropping a radio will usually break it. Sometimes it may appear to work, only to quit a week later. Typically, though, it will exhibit obvious physical damage, and it will malfunction in some major way—like being completely dead.

A dropped rig may be more reparable than you think. Sure, you probably will have to order some new case parts, but the insides may not be ruined. Let's look at what usually happens.

If there's glass, such as a faceplate over a digital readout, it probably will be broken. The readout itself, if fluorescent or LCD, may be cracked and ruined. Especially with a fluorescent readout, check for breakage before powering the rig up. Those readouts use fairly high voltages (around 90 volts) and a damaged one can short and destroy the driver chips or the transistors that run it. A broken LCD will be obvious, with a black line or ooze around the crack. Be careful, because the liquid crystal material inside is toxic. If you get any on you, wash up carefully—you don't want to ingest any of this stuff. And, of course, don't cut yourself on the glass.

The most common kind of internal damage is to the printed circuit board. A cracked board will cause all kinds of problems, and the cracks aren't always easy to find. If you suspect a crack but don't see it, look around the corners and near the edges of the board. Also, check near large parts like transformers, heat sinks, and switches. These areas are especially vulnerable. If you do see a crack, try to determine which circuit traces are affected. Sometimes you can simply bridge a few broken lines and be back in business. Other times, it's not that simple. Today's complex products, and especially miniaturized items like HTs, often have multilayer boards with conductors running *through* their centers, or in layers underneath the visible one. In cases like that, the rig may truly be irreparable. I've tried a few times, but I've never had any luck fixing cracks in multilayer boards.

Solid-State and Surface Mount

Solid-state parts, such as chips and transistors, are not very sensitive to mechanical shock, and you really don't have to worry about them unless they have visible cracks. Glass diodes are an exception, as they break in half rather easily. Other parts should be examined. Leads can break off from electrolytic capacitors, and ceramic caps can crack in half. Coils, especially those with hair-thin wires (such as IF coils), can break those wires from their terminating pins. The iron cores can crack, leaving the coil way off frequency, even though it still functions. In particular, resistors tend to break with tiny, invisible cracks. Sometimes they'll still work intermittently, as the two halves touch and separate with temperature. To be sure, wiggle any suspect resistors slightly. A cracked resistor will usually separate when moved.

Surface-mount parts are another story altogether. They are soldered with low-temperature solder in a reflow process, which is something like reheating previously soldered connections without adding new solder. In my experience, the joints are much weaker than the normal kind, and a drop to the floor may create some touchy intermittents. The parts themselves seem pretty strong, but test any iffy ones just like you would resistors. Of course, if the part breaks, you are almost certainly going to have to try to decipher its function (resistor, cap, etc.) and value from a schematic, because many surface-mount devices (SMDs) are unmarked. That's the price you pay for a full-function walkie you can slip into your shirt pocket.

If the rig fell on the switches, they may be bent or broken. Order new ones. The same goes for connectors, knobs, and moving parts in meters. Surprisingly, you may find that small incandescent lamps have survived the drop. They just don't seem to have the mass to break. Also, LEDs almost never succumb to mechanical failure.

Ben Franklin Was Right

Lightning *is* electricity. And if it hits your antenna or your power lines (the more common entry point), bye-bye radio. A direct hit is likely to do so much damage that the rig may actually melt! Most strikes, however, are not true hits. In many cases the bolt hits somewhere close by, and the surrounding charge, which is enough to knock you straight to the morgue, is what zaps your rig.

As mentioned above, many lightning strikes come into your home through your AC wiring. There's lots of wire out there above the streets, and it's all a handy target for a discharge. So, if you've been hit and the rig is dead, go straight to the power supply. After unplugging it, check the transformer for continuity. Check the fuse. Undoubtedly, the rectifiers and regulator will be open. After replacing them, you may find that there is no other damage.

If you do get hit in the antenna, the rig's front end is probably fried. FETs just don't like megavolts instead of microvolts! If there's an antenna relay, it may be fused into the receive position for eternity. A new one will do the trick. If you have solid-state (diode) TX/RX switching, many of the diodes may be destroyed. This can be tricky because there are so many of them, and you might have to check them all. Sometimes just finding them can be hard. I remember one HF rig which had a shorted switching diode (not due to lightning) that I just couldn't find. Six hours later I found it buried in a corner of the board, under some other parts. It wasn't in the service manual or the schematic. Grrrrr.

We don't always rely on Mother Nature to zap our equipment; sometimes we do it all by ourselves. Particularly in the case of new amateurs, there can be considerable confusion about the proper connections for power, audio, etc. A great deal of this is due to poor manufacturer documentation, with ambiguous wording and linguistic translation errors.

Polarity

The easiest and most commonly performed mistake is reversing the power polarity on 12 volt DC gear. It's amazing how often this happens. Once and for all time: *Red is positive (+) and black is negative (−).* Always. Really. And in a car, the chassis is negative and should go to the black lead. That is, unless you have an old, exotic European car like a VW bug.

If you do reverse the polarity, you will probably see smoke come out the back of the rig. Believe it or not, that doesn't mean the radio is destroyed. Many sets have protective diodes across their power leads. The diode is connected backwards so that it doesn't conduct in normal operation. When the polarity is reversed, the diode conducts, taking nearly all the current and protecting the rig for the few milliseconds before the external fuse in the DC power line blows.

At least, that's the way it's supposed to happen. Unfortunately, many people don't bother to fuse the power lines, so the diode conducts just like a continuous short circuit until it smokes and/or explodes. All of this can occur in a second or two. If the diode opens, which is likely, the rig will get the full brunt of the reverse voltage and be seriously damaged.

First, check the diode. It may be shorted, and there may not be any other trouble. If not, or if there is no diode, head straight for the voltage regulator. It is probably open. Sometimes a new regulator is all you need, because the old one's opening has protected the rest of the circuitry. Oh yes, be sure to replace any electrolytic capacitors connected before the regulator. Those caps just won't tolerate *any* reverse voltage. If reverse power has gotten to the rest of the circuitry, check power devices, such as audio power amps and RF finals, before anything else. Many low-level-stage parts, such as ICs and transistors, are connected through resistors or secondary regulators and won't be damaged. Small-signal diodes are almost never damaged by a power reversal. After all, they are designed to block reverse voltage anyway.

Cap'n, She Can'na Hold

High SWR will make your RF come back at you. Although all solid-state HF rigs have protection circuitry, sometimes it may not be enough. Also, some VHF/UHF rigs have no protection. At least on HF, common causes of high SWR include operator error (oops, forgot to turn off the auto antenna tuner when I changed bands), momentary mistuning of manual tuners, and antenna failures or coax damage. Generally, rigs will tolerate short-term SWR problems, but they don't like it for too long. That's one area where tubes definitely were better.

Typically, SWR damages the RF finals. They often open, so there is no RF power out. They can also short or become leaky, which will result in very low power out and probably some distortion. And, perhaps, a rather warm rig. The SWR protection circuitry may also be damaged and should be checked first.

Microphone input circuits are designed to accept small AC signals. They may be damaged by DC power or severe overload due to excessive input signals. I don't mean yelling into the mike; I mean connecting the earphone output of a tape recorder and turning it up nice and loud. Check the first transistor or IC for an open circuit.

Audio output jacks are a prime source of trouble. A short will very likely destroy the audio power amp. It is best to turn the rig off before connecting an external speaker, because the jack can short for a moment as the plug is slid in or out. Now and then, that moment is enough to cause damage.

Never ever connect two audio outputs together. Inexperienced operators sometimes do this because they want to mix two radios into one speaker. This is almost certain to damage both rigs! If you need to mix, buy or build a suitable mixer circuit which will isolate the two radios' outputs and avoid the damage caused by one rig's audio power frying the other rig.

Any time a radio is damaged via the speaker jack, head straight for the audio power amp. Also, check for the presence of an electrolytic capacitor between the amp and the jack. If there is one, replace it; it is almost certainly leaky or shorted.

Well, that's it for this month. See you again next time. 73

VK9 Norfolk Island: Ham Radio and Stamp Collecting

The Norfolk Island Philatelic Bureau has announced the issue of three stamps commemorating ham radio. The set of stamps will be issued April 9, 1991. The stamp designs feature different maps of the island and the callsigns of the island's five amateurs: VK9JA, VK9ND, VK9NI, VK9NL and VK9NS. Values: 43c, $1.00 and $1.20. A first day cover will cost $2.83 (Australian $). Additional information may be obtained from (or orders mailed to) Philatelic Bureau, Norfolk Island 2899, Australia. Thanks, VK9NS.

TN6PG and TN6PG/D2

The operations by TN6PG and TN6PG/D2 are thought to be the work of a pirate. The operator is said to QSL via G3OCA, who knows nothing about these stations.

ZS9Z/1 1990 DXpedition to the Penguin Islands

DXpeditions don't just happen, and they are not necessarily vacations. A successful DXpedition requires detailed planning, logistical support, research, and dedicated operators. The following DXpedition report, provided by N7NG, tells part of the story of the second DXpedition to the Penguin Islands of South Africa.

The South African (RSA) Penguin Islands are located off the coast of Namibia, with Namibia left in between as an "intervening DXCC country," thus qualifying the Penguins as a separate DXCC country under Points 1 and 3 of the DXCC country criteria. An application for separate DXCC status is pending, and a DXCC vote is expected momentarily.

ZS9Z/ZS1 operators N7NG, OH2BH, OH2RF and ZS6BCR arrived on the coast of Namibia November 27 and made their first attempt to land on Seal Island that same day. The only possible landing site was battered by heavy seas, so it was impossible to move a large quantity of DXpedition gear. Some operators were put ashore, and they found traces of the original German DXpedition to that island.

On Wednesday, November 28, a more successful attempt was made to land on a neighboring rock called Penguin Island. The weather was excellent and the landing area seemed much more favorable, but it was situated on the wrong side of the rock, which blocked an unobstructed shot at the northern sector, and blocked all of the U.S. and Japan on long path.

To avoid any unpleasant surprises, the group brought more than one mile of RG8/U coax to reach the highest tip of the island, and to have the beams out in the clear. They spent one whole day under intense sun conditions, carrying and mounting a 40-foot Rohn with a Hy-Gain TH5 on top. Another tower supported a Hy-Gain 103BA, while Butternut verticals were used for the lower bands. We sincerely hope that the ZS9Z/ZS1 signals proved worthy of that effort.

Some 33,200 QSOs were made during the six days of operating. Two ICOM IC-735s with amplifiers were supplied with 6 kW of generator power. The first days and the weekend were spent on selected bands to provide everyone with at least one contact. Some RTTY and WARC band operating was launched for the first time from Penguin, and a brief showing was made on 80/160 toward the very end.

Facilities on the island were highly limited, and the operating was done from the remains of a guano community that had existed there a long time ago. The birds were relatively agressive, and there were nests everywhere. The conditions were next to hazardous, and the smell was horrible. All the nests in the vicinity of the operating site and on the way to the towers were protected by markings.

Despite many rumors to the contrary, landing permissions were on hand for both Seal and Penguin Islands. A South African (RSA) delegation from the Department of Nature and Environmental Conservation landed during the operation to make sure that the ecological balance on the island was not disrupted.

The last 20 hours of the operation used Butternut verticals only, and the operation wound up immediately after sunrise on December 6, 1990.

Many logistical phases had to be successfully completed to secure this DXpedition. Derek Moore V51DM played a major role in providing assistance and supplying a master cable to reach the top of the island, and in placing his fleet of air rafts at the disposal of this DXpedition. Thanks are also due to Harold Lund ZS6WB in Pretoria for loaning us the generators, and for coordinating and supporting railway container shipments through South Africa and providing a four-wheel drive vehicle with a trailer for nonstop driving from ZS6 to the coast of Namibia, a 30-hour drive. And, we wish to credit Ian Sutherland ZS9A for offering highly valuable assistance in planning the landing and the setup on Penguin Island. A major local organizing burden was borne by Chris Burger ZS6BCR, one of the operators.

The cost of logistics for an operation of this magnitude was extremely high, but many institutional and private parties have moved in to offset the logistical expenses.

Please note that V51Z (CQ WW CW contest only) and the Penguin Island DXpedition will be QSLed via Martti Laine OH2BH. The rescheduled ZS9Z operation from Walvis Bay (active during mid-December) will QSL via ZS6BCR.

Notes from FN42

Several hams have heeded my plea for hambassadors. I guess they just couldn't pass up the offer of a FREE airmail subscription to 73 Amateur Radio Today. *Offering to become hambassadors were Charles Martin AB4Y, on his way to Saudi Arabia for a year; Mike Lazaroff KB3RG/CU3LF, presently on Terceira Island in the Azores; and Robert Wright XQ6EK, a resident of Chile and radio officer on merchant vessels.*

Another hambassador has been added through the efforts of Bill Brown WB8ELK, our managing editor. Hans van de Groenendaal ZS6AKV will step in to keep us informed of happenings in South Africa. Many of you know Hans through his AMSAT efforts and ham ballooning. One of his articles, "Give a Lift to Your ARC," on Balloon Carrying Amateur Radio, or BACAR, was in the March 1990 issue of 73.

I am sure much has been happening in these countries during the past several years. No one has reported from Saudi Arabia since December 1984, from Chile since May 1988, and from Portugal/Azores since July 1988.—Arnie, N1BAC

Roundup

Greece *A letter from the Greek Mountaineers' Club: 5; Aristotelous Square, Thessaloniki 54624, Greece.* This report describes the radio activities of members of the Greek Mountaineers' Club in the Caucasus region last August. The club operates a licensed VHF rescue network (slightly above the 2m amateur band). On two occasions in 1990, the network proved invaluable in initiating and coordinating mountain rescues by helicopter. Many members also engage extensively in mountain-topping amateur radio activities.

The club conducts ongoing tests to explore and develop the network's capabilities. In the course of these tests, radio amateurs SV2AHT, SV2AHJ, and SV2BBQ took along HF and VHF equipment on a mountaineering expedition to the Caucasus region (in the U.S.S.R.) last August. Two meter handhelds by Yaesu and ICOM provided communications during the ascent of Mt. Elbruz (5,642 meters). No amateur contacts were made, as amateur activity in the 2m band was conspicuous by its absence.

SV2AHT made a number of interesting OSOs in the 20m band in the period of August 21 to August 30, 1990. The station was located at 4,200 meters above sea level. Temperatures reached −10°C. *[Was that the high or low, I wonder? Brrrrrrr!—Arnie]* Stations contacted include VK, 5B, SV, N, UA, KA, DJ, and I.

The transceiver was a GCR-250 all-band, all-mode rig manufactured in Greece. Running at low power (8–10 watts out), it displayed fairly low power consumption. The NiCd batteries powering the unit were recharged by portable solar cells. The antenna was a 20m dipole. 73s from Vassilis Toulis, SV2BBQ. *[Vassilis sent along some beautiful photos and they will be presented in this and succeeding issues.—Arnie]*

Japan *From the JARL News.* On November 14, 1990, 55 members of the 32nd Japanese Antarctic Research Expedition left Tokyo on board the icebreaker *Shirase* for a two-year tour of observation duty in the polar regions. Mr. Hara JA1AN, president of JARL, along with other JARL members, met to see them off.

A week earlier, Mr. Toyoshi Arisawa JA4EDV, together with three other members, all in charge of communication on the expedition, attended lectures on amateur satellite operation delivered at the Technical Laboratory of JARL. Needless to say, acquiring such knowledge will prove a must in their attempts to communicate via satellite from amateur radio stations 8J1RL in Showa Base and 8J1RM in Asuka Observation Base. Eleven members of the team hold amateur radio licenses. They will be eager to receive news, and anticipate both stations to be on the air from 0930 to 1030 UTC, mainly on 7, 14, and 21 MHz. *[A full listing of JARL Beacons was listed in this issue of* The JARL News, *but it's too lengthy to present here. Look on the 73BBS under 73INTL SIG, "JARL Beacons."]*

BRAZIL

Carlos Vianna Carneiro PY1CC
Afonso Pena 49/701
20270 Rio de Janeiro
Brazil

Best wishes to all in this coming 1991. May there be Peace and Fraternity in this world we live in.

We are having a kind of QRP boom in Brazil, as only CW QRP equipment is being produced the artisan way in São Paulo. The equipment provides 5 watts output and is priced at $180 to $200, thus allowing beginners to start CW operations reasonably cheap. We've heard about a new QRP rig from the Japanese, with crystal filters and plenty of other items "for JUST $1,300"!!

Coming back to home-brew QRP equipment, I am looking for a linear amplifier schematic that will bring 3–4 watts up to 30–40 watts. If anyone has a good one please send a copy to me directly or to Arnie at *73* and he will send it to me.

I think many Brazilian hams are now discovering the Islands On The Air (IOTA) award program, and as we have islands by the hundreds along the coast, we are trying to develop DXpeditions by interested groups to "shake up" the sleepy amateurs all over.

As my part of this shake-up, I am presenting two DXpeditions, one to Trindade Island and the other to São João Island. Best wishes for the coming year. *[The trip to Trindade Island will be presented later.—Arnie]*

São João Island, IOTA S.A. 41. Raising the international interest for its program, the IOTA is offering a new potential to radio amateur development, and especially for the adventures of DXpeditions, like this one to São João Island. That old feeling for adventure once again "pushed" Ronaldo PS7AB and Tino PT7AA toward a different and exciting DXpedition to São João Island, officially known as Maiaiu Island, some 30 miles off the Brazilian coast north of Maranhão state.

This island is part of an archipelago with tens of smaller islands, some of them inhabited by fishermen and their families. On São João Island is a 35-meter-high lighthouse erected by the Brazilian Navy.

Leaving Natal City by bus, they took some hundred kilos of equipment over extremely damaged roads and prehistoric wooden bridges for about 2,200 kilometers. On reaching Apica-Açu village north of Maranhão state, they boarded a small fisherman's boat for a 13-hour trip, four of the hours on open sea. This was the most unexpected "rally" for Ronaldo PS7AB, not used to such adventures.

For Tino PT7AA things ran differently, coming straight from São Luiz City, the capital of Maranhão, by boat, also with high seas during the 48-hour trip, with 10-meter-high waves during the 160 mile travel, praying all the time for the small boat's safety!

And then, São João Island, a real paradise, safe from any ecological damage, splendid and rich tropical flora, endless cocoa tree groves, lovely birds of all colors, as the Guará in its glorious red color, and a sea of limpid waters, a tepid habitat for an enormous variety of fish, shrimp and crustaceans, clear sand and sandy hills as beaches, a real dream.

The island is located at 01°17'S–44°54'W, 30 miles off the coast of Maranhão, fishermen's boats the only way to shuttle over.

With the Navy "permit" to share part of the lighthouse, we had rooms and bathrooms, and power. We had our "shack" for the Kenwood TS-430, ICOM IC-725, AT-130 and AT-250 couplers, a Brazilian Spectrum electronic keyer, Shure 444D microphone, and two vertical Electril multiband antennas, one of them up 35 meters on top of the lighthouse.

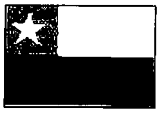
Tino operated as ZX8CW (CW mode) and Ronaldo as ZX8DX (SSB mode) from 5 to 13 October 1990. They made 3,037 phone QSOs in 104 countries, and Tino made 1799 CW QSOs in 67 countries. Using Vee antennas, they got very good results from America and Europe, and not so good for Asia and Africa.

São João Island is 7½ km long and about 1½ km wide, with the lighthouse on one end, and a fisherman's village on the other, with a beach called, "Bate o Vento" (wind blowing). The island has a normal temperature, about 28°C and almost no rain.

I asked Tino by radio after the expedition was over, "So Tino, was it all worthwhile?" The answer came back straight and sure, "Of course, Carl! It was marvelous, no matter what problems, and we will never forget the fantastic scenery of São João Island."

Special thanks from the DXpedition members to the Navy people living there, four families; and a very, very special 73 to Vanderley Valente, a Navy corporal for 10 years in charge of the lighthouse, for their friendly sympathy.

Photo A. SV2AHT, SV2AHJ, and fellow mountaineers with the HF rig.



CHILE
Robert M. Wright XQ6EK
Casilla 1259
Osorno
Chile
South America

Hello to all amateur radio operators. I am very glad to become the hambassador for Chile. Let me tell you something about myself.

I am a radio officer on board merchant vessels, holding licenses as such in the countries of Great Britain, Panama, Liberia, and the United States. I have five years of seatime and have worked many years as a radio operator at coast stations, such as WPD and WKM.

I hold nine amateur radio licenses, Canada Superior Class VE2OST, U.S.A. Extra N4VBG, Diego Garcia VQ9MW, Chile Superior Class XQ6EK (XQ is a First Class prefix in Chile, only 100 in the entire country), ex-DJØGB in Germany, and many others. I am 26 years old, 11 years an amateur operator, married (my XYL's callsigns are CE6POP and KC4LQD), and live on a dairy farm about 1,000 kilometers south of Santiago when not working my eight months a year at sea.

At my home QTH, I work an ICOM IC-735, amplifier of 500 watts or so, and a Cushcraft R-5 ground-mounted antenna. I also have a 100-foot tower where I will soon install a yagi or quad beam antenna. I am very active on 2 meters as well. I speak Spanish, German, and English.

I hope I have a chance to talk to many of you in the years to come, and I ask that all amateurs of Chile send me information of happenings in their areas. 73 to all.

LITHUANIA
Jonas Paskauskas LY2ZZ
PO Box 71
Siauliai 235400
Lithuania

The Lithuanian Amateur Radio Conference will be held in Vilnius, Lithuania during the first week of June 1991. The conference will last approximately 7–10 days. It will start in the capital, Vilnius, then move on to Kaunas, Panevezys, Siauiiai, and Palanga, a resort town on the Baltic Sea.

To date, 26 amateurs from outside Lithuania are planning to attend: 15 from the U.S.A., three from Canada, four from Germany, two from England, and two from Scotland.

If you wish more information, or wish to attend, please contact me at the above address with your requests. I'm looking forward to the conference and to meeting some of the hams that I have talked to on the air. *[The conference scheduled for last June had to be canceled due to the political climate at that time. We hope nothing will prevent the conference this year.—Arnie]*

Lithuanian yachtsmen are in the process of outfitting a sailboat for a trip around the world, to last approximately 18 months. The purpose of the trip is to show the flag and visit major Lithuanian colonies. The crew of 18 will include a licensed radio amateur with a special event callsign. More on this later, as more information becomes available.

NEW ZEALAND
Des Chapman ZL2VR
459 Kennedy Road
Napier
New Zealand

Now that 1990 is over, the NZART year can be viewed in retrospect.

Late 1989 saw the beginning of NZART managing the entire administration of amateur examinations on behalf of the New Zealand Frequency Service (NZFS) of the Department of Commerce. Applications are processed by NZART HQ, the examination centres set, the preparation and distribution of the examination papers, and the arranging with the branches for approved members to supervise and conduct the exams. When the exam is completed, the papers are returned to NZART HQ for marking, and the candidates are advised of the results directly from NZART HQ within several weeks of the exam date. Before, when the NZFS supervised and conducted the exams, it took two to three months.

The NZ Frequency Service is also favourably considering the transference to NZART of the administration and testing of candidates for Morse code. We anticipate this will take place before March 1991.

New school radio clubs have formed during the year. The increased interest in amateur radio has become evident by the many school clubs heard on the air during lunch breaks, and many schools are now featuring amateur radio in their Open Days.

From 1 November 1990, the NZFS approved the use of 2 meters (144–148 MHz) by Novice operators. The regulatory body refused the initial request from NZART in March, but after further submissions, agreed. So now, if there are reciprocal rights between NZ (ZL) and your country, as a visiting Novice operator, you will be able to operate on the 2m band.

This year ZL amateurs are participating in an IARU International Monitoring Service. From 1 March 1990 through 24 February 1991, amateurs and nonamateurs (listeners) are monitoring set frequencies outside the ham bands 24 hours each day, to identify the unused or rarely used parts of the radio spectrum adjacent to the amateur bands.

NZART Conference, 1991

The 1991 NZART Conference will be held at Marton, NZ. The "Martian Conference" venue will be an agricultural training facility, called Flock House, near Marton. The venue has graded accommodation facilities as follows: Executive—$81.70 per day; Business, $57.15 per day; and Thrifty, $30.85 per day. If you prefer to camp, it's $3.00 for adults and $1.62 for children per day.

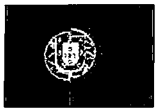
If any overseas amateurs are visiting during May/June, the conference dates are 31 May through 3 June, a full weekend of amateur radio activities centered around the annual meeting of NZART, and plenty of social activities as well. The accommodation and conference venues are all within the complex at Flock House; therefore, you can walk from place to place with no worries about transport.

Recreational facilities are good—an indoor heated pool, squash courts, tennis courts, and a sports field. If any of my overseas readers are interested, write to me and I will send your letter on to the organizing secretary.

New Bands for ZL Recently, as a result of submissions made on our behalf by the Frequency Management Technical Advisory Group (FMTAG) of NZART, the NZFS made two new bands available to ZL amateurs. The two bands are 165 to 190 kHz (1700m), with a maximum EIRP of 5 watts; and 922 to 927 MHz (32cm), with a maximum EIRP of 25 watts. FMTAG is presently formulating possible uses for these two new bands, maybe in some specialty communications areas. The bands are available on application to the holders of the ZL General licence.

Other items: The new QSL address for ZL is: B.E. Stewart ZL2RR, PO Box 857, Wanganui, New Zealand.

Terry ZL3QL, NZART President, is on temporary posting to Los Angeles with Air New Zealand as a 747 captain. He should be on the air from L.A. during his time there.



PORTUGAL/AZORES
Mike Lazaroff KB3RG/CU3LF
PCS Box 1687
APO New York 09406

I'm a 15-year veteran of the United States Air Force and currently stationed on Terceira Island in the Azores (CU3-land). I would love to write reports on the Azores and ham radio.

Operating from here is a ball—the bands are open all the time, and the CU call seems to add 15 to 20 dB to your signal! I'm active on all bands, 160 to 10m on CW, SSB, packet, and RTTY.

[For those amateurs in Portugal, feel free to send your ham information to Mike for inclusion in the column, or you can send the info directly to me. —Arnie]

Number 25 on your Feedback card

UPDATES

Jan. '91 "Circuits"

See the schematic for KB4ZGC's regulated voltage distribution box on page 58 of the above issue. Note that the inputs to regulators 7808 and 7806 should be joined to the line from the output of LM317, in the same manner that regulators 7805 and 7809 are.

Jan. '91 "Frequency Standard"

See the above issue for the article, "High Precision Frequency Standard," by Johnson, on page 9.

John H. Davis, Chief Engineer WJSP-TV/FM: "It is no longer possible to rely on a TV station's sync to atomic precision, even during network programs, except in a relatively few cases. The development of affordable digital frame synchronizers in the past decade has changed things. Nearly all stations use one or more of them.

"The frame synchronizer digitizes incoming video, then plays it back in step with the station's *local* sync generator, which is usually *crystal controlled.* There are a few exceptions, but well over 80% of stations are referenced to a local crystal 100% of the time. Mr. Johnson's circuit seems solidly designed, but be very sure of your reference!"

Bradford E. Scott WD9HDZ, engineer at WCET: "A network signal processed through a frame synchronizer no longer maintains the rubidium-standard accuracy, but instead exhibits the characteristics of the local station's sync generator, which usually uses a quartz crystal. This local oscillator is adjustable, and must be periodically calibrated. The FCC requires that broadcast TV stations keep their color subcarriers accurate to within plus or minus 10 Hz, or within 2.79 times 10 to the minus 6th percent. Thus, a calibration reading taken from a station using frame synchronizers may be inaccurate by that amount."

Paul D. Roehm KB9CLA, works for WRTV: "In all but the smallest TV markets, incoming network video is run through a frame synchronizer. Because of this, the accuracy of the 1 MHz signal generated by the PLL would have the accuracy of the sync generator at your local television station.

"All network programming is sent to your local station by satellite. All satellites, even geostationary ones, have Dopper shift. Though small, about 1 Hz, the shift may cause short-term errors in your frequency standard. Where Mr. Johnson lives, in Los Angeles, the local TV signal is coming from the same source as the network, rather than from the satellite. If you live in Los Angeles or New York, the circuit will work for you.

"All is not lost, however. Some stations, including the one I work for, are locked to the WWV 60 kHz signal as a condition of their license. If you can change the system to lock to their visual carriers, then you are home free." 73

SPECIAL EVENTS

Number 26 on your Feedback card

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

MARCH 2

ABSECON, NJ The Shore Points ARC will hold its 9th annual hamfest, "Springfest '91", at Holy Spirit High School. Doors open at 9 AM. Set-up at 7 AM. Reservations will be accepted for tables in the heated indoor selling area. Outdoor tailgating space available, weather permitting. Limited AC. Sellers: $5 per 8' table; buyers: $4. Talk-in on 146.385/.985. Write to: *SPARC, P.O. Box 142, Absecon NJ 08201.*

ALAMOGORDO, NM The Alamogordo ARC will hold VE Testing at the Alamogordo Mid High School, South entrance, beginning at 12:00 noon. Contact *Marilyn Redman, Public Information Officer, Alamogordo ARC, P.O. Box 1191, Alamogordo NM 88310.*

CAVE CITY, KY The Mammoth Cave ARC will sponsor their 15th annual Glasgow Swapfest at the Cave City Convention Center, beginning at 8 AM Central time. Admission is $4 per person, tables $5 each. VE exams, walk-ins welcome. Talk-in on 146.34/.94. Contact *N4HCO, 1379 Whites Chapel Rd., Glasgow KY 42141.*

MARCH 3

YORK, PA The Fourth Annual York Springfest (Ham & Computer) will be held at the Dover Fire Hall starting at 8 AM. Admission $4, unlicensed spouse and under 12 free. Tailgating $1. Inside tables $10. VE Exams. Talk-in on 146.37/.97 and 147.93/.33. Contact *York Springfest, P.O. Box 316, New Freedom PA 17349-0316. (301) 239-3878.*

ROSTRAVER TOWNSHIP, PA The Two Rivers ARC of Mc Keesport will hold its 18th annual Swap and Shop at the Rostraver Volunteer Fire Hall from 8 AM–3 PM. Admission is $1. Contact *Mr. Michael Kowalcheck KV3L, (412) 751-9657.* Directions will be available on the WA3PBD repeater, 146.13/.73.

MARCH 8

ST LOUIS CITY, MO The Jefferson Barracks ARC will hold their 31st annual Amateur Radio Auction at the Concordia Turner's Hall. Doors open at 5 PM and the Auction starts at 7:30 PM. Talk-in on 144.61/145.21 and 146.34/.94 repeaters after 5 PM. Contact *Carl H. Hohenberger WB0BPZ, 5266 Parker Ave., St. Louis MO 63139-1340. (314) 351-7084.*

MARCH 9

TULLAHOMA, TN The Middle Tennessee ARS will hold an Old-Fashioned Swapfest at the Tullahoma TN Airport, Hanger #6. Talk-in on 146.10/.70. Contact *Richard Johnson W4SFF, 109 Dogwood, Winchester TN 37398.*

MT. ARLINGTON, NJ West Morris Wireless and Splitrock ARA will sponsor the annual North Jersey Hamfest at the Mt. Arlington Sheraton beginning at 8 AM. Set-up at 6 AM. VE Exams begin at 8:45 AM. Admission $5, XYLs and children free. Tables $15. Talk-in on 146.985/.385 and 223.860/2.260. Mail table registrations to *PO Box 610, Rockaway NJ 07866,* until Feb. 28. Late registration, call *Bill WR2M, (201) 770-0242 till 10 PM,* or *Bernie WB2YOK, (201) 584-4423.*

ROSELLE PARK, NJ The Student Body of Roselle Park High School and the Old Bridge Radio Assn. will host the Roselle Park Family Computer/Ham Festival. Flea Market from 9 AM–4 PM, plenty of tailgate space. Admission $5. Talk-in on 146.520 simplex. Contact *Computer Exposition and HamFest, Roselle Park High School, 185 West Webster Ave., Roselle Park NJ 07204. (201) 241-4450; or BBS, (201) 241-8902 (24hr 300/1200).* Directions: Garden State Parkway Exit 137 to East on Westfield, 3rd light, left on Locus, left after RR underpass.

MARCH 10

BRISTOL, CT The Insurance City Repeater Club will hold its annual Amateur Radio/Computer Flea Market at the Bristol Eastern High School from 9 AM–2 PM. Admission is $3. Six foot tables are $12. Contact *Chuck Motes K1DFS, 22 Woodside Lane, Plainville CT 06062, (203) 747-6377.* VEC Exams by registration only. Contact *Sue Fredrickson WM1B, PO Box 165, Pleasant Valley CT 06013* as early as possible. Talk-in on 146.28/.88.

INDIANAPOLIS, IN The Morgan County Repeater Assoc. will sponsor the Indiana Hamfest at the Indiana State Fairgrounds Pavilion building. Admission is $7 at the door. 8' Flea Market tables (with space), $12 each. No space will be sold without a table. Set-up Sat. Mar. 9 from 3–9 PM and Sun. Mar. 10 from 6–8 AM. Talk-in on 145.25. For reservations, send SASE before Feb. 23 to *Aileen Scales KC9YA, 3142 Market Place, Bloomington IN 47403. (812) 339-4446.*

MARCH 15-17

ORLANDO, FL The 45th annual Orlando HamCation and Computer Show, sponsored by the Orlando ARC, will be held at the Central Florida Fairgrounds. The Exhibitors Area will be located in a 44,000 square foot air conditioned building. Overnight RV parking at reasonable cost. The Host hotel is The Ramada, Orlando Central at 3200 West colonial Drive. FCC Exams on Sunday at the Ramada convention Center. Complimentary continuous bus service from the Ramada to the Fairgrounds. Contact *Dick DiVittorio KB4QKP, General Chaiman 1991, PO Box 547811, Orlando FL 32854-7811.*

MARCH 16

SCOTTSDALE, AZ The ARCA Spring Hamfest, hosted by the Scottsdale ARC, will be held from 7 AM–4 PM at the Scottsdale Community College. Admission is $2 per car. Swap space $5. Talk-in on 147.18/.78 and ZIA Link. Contact *Allen Sklar AA7BJ, PO Box 10878, Scottsdale AZ 85271-0878* or *(602) 491-0802.*

FLEMINGTON, NJ The Flemington Hamfest, sponsored by the Cherryville Repeater Association II Inc., will be held at the Hunterdon Central Regional High School Fieldhouse from 8 AM–2 PM. Wheelchair accessible. Free parking. Tailgating. VE Exams. Talk-in on 147.975/.375 MHz duplex and 146.520 MHz simplex. Contact *Marty Grozinski NS2K, c/o Cherryville Repeater Assoc. II Inc., PO Box 308, Ouakertown NJ 08868. (908) 806-6944* or *(908) 788-4080.*

MARSHALL, MI The Michigan Crossroads Hamfest, sponsored by the Southern Michigan ARS and the Marshall High Photo Electronics Club, will be held at the Marshall High school from 8 AM–3 PM. Set-up at 6 AM. Tickets $2 in advance, $3 at the door. Free parking. Table Reservations: 75¢ per foot (min. 4 feet) reserved until 8 AM. Send SASE to *SMARS, PO Box 934, Battle Creek MI 49016,* or call *Wes Chaney N8BDM, (616) 979-3433.* License Exams start at 9:30 AM. Pre-registration requested. Include Form 610, SASE and $4.95. Make check or M.O. payable to *ARRL VEC* and send to *Barry Pollack, 330 East Berry Rd., Rives Jct. MI 49277.* Exam charge subject to change.

HUDSON, NH The Interstate Repeater Soc. will hold its annual Flea Market at the Lions Club Hall from 9 AM–3 PM. Set-up at 8 AM. Admission $2. Talk-in on 146.85, 224.46 and 449.625 IRS repeaters. Contact *Wayne Canino KA1MKH, (603) 895-9033.*

MARCH 16-17

FORT WALTON BEACH, FL The Playground ARC will hold their 21st annual North Florida Ham/Swapfest at the Shrine Fairgrounds. Doors open at 8 AM both days. Free Parking. RV parking for $10 per night. Admission $3 in advance, $4 at the door. Swap tables $10 for one day, $15 for both days. Talk-in on the 146.19/.79 club repeater. Contact *Playground ARC, PO Box 873, Ft. Walton Beach FL 32549.*

MARCH 17

MAUMEE, OH The Toledo Mobile Radio Assn. will hold a Hamfest at the Lucas County Recreation Center from 8 AM–5 PM. Advance admission is $4, $5 at the door. Talk-in on 147.27 and 442.85 repeaters. Contact *Bob Hanna K8ADK, 2154 Circular Drive, Toledo OH 43614.*

BRAINTREE, MA The South Shore ARC will hold its annual Flea Market at the Viking Club from 10:30 AM–3 PM. Free parking. Set-up at 9 AM. Admission $1. 8' tables for $10 (which includes one free admission per table), if paid for in advance before Mar. 13. Write to *Hal Jones WB1ABM, 48 Saning Rd., N. Weymouth MA 02191,* or call *(617) 335-5777,* evenings. Make checks payable to the South Shore Amateur Radio Club. Non-reserved tables are $12.

STERLING, IL The Sterling-Rock Falls ARS 31st annual Hamfest will be held at the Sterling High School Field House from 7:30 AM. Set-up Sat. Mar. 16 from 6–9 PM, and on Sun. Mar. 17 at 6:30 AM. Advance tickets $3, $4 at the door. Tables $5 including electricity. Bring your own cord. Talk-in on 146.25/.85 W9MEP repeater. Contact *Sue Peters, Sterling-Rock Falls ARS, PO Box 521, Sterling IL 61081,* or call AC at *(815) 625-9262.*

MARCH 21-23

WASHINGTON, DC A 3-day hands-on Personal Computer Interfacing workshop will be held at the Virginia Tech campus. Contact *Dr. Roy Jones, (703) 231-5242 or (703) 231-6473.*

MARCH 23

UPPER SADDLE RIVER, NJ A Ham Radio Flea Market, sponsored by the Chestnut Ridge Radio Club, will be held at the Saddle River Reformed Church Education Building. Tailgating $7. Tables $10. Donation $2. Contact *Jack Meagher W2EHD, (201) 768-8360.*

ELIZABETHTOWN, KY The Lincoln Trail ARC will hold its 11th annual Hamfest at the Pritchard Community Center. Walk-in VEC Exams (fee $5.25) begin at 9 AM fee $5.25. Show original license and a copy of same. Free parking. Security provided. Set-up starts at 6 PM the night before. Advance tickets $4, $5 at the door. Vendor spaces are $5 each (includes one table and one chair). Talk-in on 146.52 and 146.38/.98. For reservations contact *Whitey Hensley WD4GDA, PO Box 342, Vine Grove KY 40175. (502) 877-2234.* Send check or money order and a SASE. For info call *Chuck Strain AA4ZD, (502) 351-1715.*

MARCH 24

TRENTON, NJ The Delaware Valley Radio Assn. will sponsor Hamcomp '91 at the New Jersey National Guard 112th Field Artillery Armory, Lawrence Township, from 8 AM–2 PM. Free parking. Wheelchair accessible. Advance tickets $3, $5 at the door. Indoor selling spaces are $15 (wall space) or $10. Outdoor spaces are $8. Sellers must provide their own tables. Set-up at 6 AM. Talk-in on 146.07/.67. Contact *Hamcomp '91 c/o KB2ZY, 33 Bowne Station Road, Stockton NJ 08559.* Please SASE.

MADISON, OH The Lake County ARA will hold their 13th annual LCARA Radio/Computer/Electronic Hamfest at Madison High School from 8 AM–3 PM. Admission is $4. Indoor fox hunt will be at 1 PM on 2 meters. VE Exams begin at 8:15 AM and cost $5.25. Tables: $5/6', $6.50/8'. Talk-in on 147.81/.21 and 222.90/224.50 (PL 141.3). Contact *Roxanne, Lake County Hamfest, 5777 Fenwood Ct., Mentor-on-the-Lake OH 44060.* Phone *(216) 257-2036* from 6–9 PM weekdays or 10 AM–4PM weekends, or *(216) 352-6756* 10 AM–4 PM weekdays.

MARCH 30

TEXARKANA, TX The Four States ARC will sponsor its second annual Swap Meet at the Four States Fairgrounds at Loop 245 and I-30, beginning at 8 AM. Admission $1. Tailgate party with cover available if WX is bad. VE Exams at 1 PM. Talk-in on 146.62 –600. Contact *Travis Bailey K5AVH at (903) 792-2080.*

SPECIAL EVENT STATIONS

MARCH 2-3

OPP, AL The Covington ARS will operate Station KZ4S from 1400Z Mar. 2–0200Z Mar. 3, to commemorate the 32nd annual Opp Jaycees Rattlesnake Rodeo. Frequencies: 25 kHz up from the General 80, 40, 20 and 15 bands and approximately 28.385 on Novice 10 meter band. For commemorative QSL and brochure, send QSL card and business size SASE to *C.A.R.S., c/o Kay B. Ezell N4VJI, PO Box 244, Opp AL 36467.*

MARCH 8-10

SWEETWATER, TX The Nolan County ARC will operate Station WR5B from 1500Z–2400Z Mar. 8–10, during the world's largest rattlesnake round-up. Frequencies: 20 and 40 meter General phone bands plus 10 meter Novice. For certificate send QSL and large SASE to *WR5B, PO Box 825, Sweetwater TX 79556.*

MARCH 16-17

ST. PATRICK, OH The Farout ARC of Dayton will operate Station WB8SMC/8 from 1700Z Mar. 16–1700Z Mar. 17. Frequencies: Lower halves of: 80, 40, 15, 10 meter Novice CW and 10 meter Novice phone; 80, 40, 20, 15 meter General phone. Send a business size SASE to *Farout ARC, PO Box 9181, Dayton OH 45409-9181.*

PISCATAWAY, NJ The Piscataway ARC will commemorate the historic Voice of America relay station, WBOU, that operated in Piscataway from 1942–1964. PARC members will operate using their own call signs/VOA from 000Z Mar. 16–2400Z Mar. 17, in the lower General portion of 75, 40, 20, and 15 meters, and the Novice 10 meter band. For certificate, send QSL and 9x12 SASE to *PARC, Attn: KB2UV, PO Box 1233, Piscataway NJ 08854.*

MARCH 23-24

The Virginia Beach ARC will operate Station WA4TGF from 1400Z Mar. 23–2000Z Mar. 24, to commemorate the 100th anniversary of the arrival of the Norwegian Lady to our shores. Frequencies: 3.875, 7.275, 14.275, 21.275 and 28.363 MHz. A certificate will be available to all amateurs contacted. Send QSL and SASE to *VBARC, PO Box 62003, Virginia Beach VA 23462.*

RANDOM OUTPUT

David Cassidy N1GPH

14.313 MHz

I happened to scan by 14.313 MHz the other day, and I couldn't believe what I heard. The same people who were demonstrating their ignorance over two years ago are STILL on that same frequency. . . arguing the same stupid points . . . being QRMed by the same idiots . . . blah blah blah. . . yak yak yak . . . yawn, yawn.

I have managed to keep my nose out of this little ego battle, figuring that as soon as the participants got bored they would move on to other pursuits befitting their intelligence—like finger painting. Sure, I've mentioned in passing how dumb the whole thing is, but I haven't really addressed the issue directly. The thing that has bothered me the most about the whole ridiculous mess is that it takes up a good chunk of the 20m phone band, which keeps the rest of us from using those frequencies for more productive and enjoyable purposes. I also get a bit angry every time I remind myself that this demonstration of idiocy on the part of American amateurs is being monitored by people all over the world. Some of those foreign listeners will remember what they've heard from the U.S. hams when it comes time to ask for favors at the next WARC. I have also spent a little time considering the example these brainless wonders are setting for newcomers or potential hams.

I went so far as talking to one of the participants a few months ago. I wanted to see for myself if this guy is as big a fool as he appears to be. Yup. . . he is.

I've sought out and listened to the so-called bulletins. Total tripe.

I've even spent several hours just monitoring that portion of 20m, where most of this crap is displayed. I've listened to all sides. I've heard hour after hour of non-identified, intentional QRM.

I've heard virtually everyone who considers himself involved in this mess and what they have to say.

Here's what I've discovered . . .

What we have here, ladies and gentlemen, is a small group of very lonely people. The biggest thing in their life—THE BIGGEST—is the small bit of attention they are able to capture by being pompous and boring on 14.313 MHz. These peoples' lives are so utterly devoid of anything even remotely worthwhile, they have resorted to the only thing they know to justify their existence. They have created a situation, and placed themselves at the focus of it, for no other purpose than to give themselves a reason to get out of bed in the morning. Instead of working constructively and through proper channels to correct what they see as a problem on the amateur bands, these self-appointed keepers of the radio truth have personalized their disagreements. They're not interested in solving problems. Their only motivation is ego gratification. These are true outsiders, folks. The kind of geeks that even the nerds won't associate with. It's funny how important something can become, when the rest of your life is so unimportant.

Try to look at this situation as if you had just come across it today. What would your reaction be? I have explained the conflict to several people who were totally unaware of the whole thing. Every single person had the same response: "Aren't there more important things in the world to spend time and energy on?" All of my non-ham friends who have asked for an explanation of the utter foolishness they hear coming out of my speaker have simply laughed. They're not just laughing at those heard on the radio, they're laughing at the entire amateur radio community for letting such a stupid situation take up so much time, thought and energy. They're laughing at you and me, friend. I can't say that I blame them.

So. . . what's the solution? True to form, the ARRL's response was something like, "We're not involved. It's not our problem." So much for the self-appointed voice of American amateur radio.

The FCC, trying to allow us to fulfill our promise of being "self-policing," has asked those involved to work out their differences. Since those involved have no interest in working out their differences, this has had no effect. Remember, these bozos are getting a barrelful of self-importance out of this. They have actually convinced themselves that what they think is important—enough to cause the inconvenience of thousands of amateur radio operators around the world. Even though the FCC has warned us that if they have to step in to solve the problem they will do so by a swift and privilege-revoking rule change, all the participants can do is continue to bother the FCC with their petty grievances. In frustration, the FCC has stepped up their monitoring and started to levy some stiff monetary penalties (though I haven't heard of anyone who has had his license revoked). The operators who have received fines are wearing them like a badge of honor, further proving their utter stupidity.

One thing that we all can do is make sure we are not providing an audience for these clowns. (This is why you will notice that I haven't mentioned anyone's name or callsign. I know who they are, but I simply refuse to feed their egos by printing their names or callsigns.) If you are monitoring the frequencies, you're part of the problem. If you're monitoring the frequencies AND throwing in an unidentified comment every now and then, you are causing intentional interference.

If you've spent any time around children you know that they will do almost anything, including misbehave, to get an adult's attention. Sometimes the best thing an adult can do when a child is misbehaving is leave the room until the child discovers that his bad behavior will not be rewarded by the attention he craves.

That's what we have here. We have a small group of children who are displaying their desperate need for attention. If we continue to give it to them, we are just reinforcing their behavior. If we all could just leave them alone, they would eventually discover that nobody's listening. Nobody cares. The adults have left the room. 73

Almost Excellent

You may expect the usual conditions that prevail around the equinoxes when the ionosphere recovers from its winter doldrums and becomes active again for HF DXing. Since we are slightly past the peak of sunspot Cycle 22 and beginning the slow decline in solar activity, conditions will be excellent. However, they might not be quite as good as conditions during this month in 1989 and 1990. That is, solar flux may be down a bit compared to those two years, and there are likely to be more fair (F) than good (G) DX conditions (see the calendar below).

You can always determine when to operate under the best possible conditions by using three sources of information: the daily propagation forecast chart, the band-time-direction chart, and WWV at 18 minutes after each hour. With these sources, you can pick the best possible times to work that DX you are looking for.

In general, the first two weeks are expected to have better conditions than the last two weeks. But, as usual, there will be occasional good (G), fair (F), and poor (P) days intermixed.

A good (G) day will show low planetary "A" indexes (below 10 or so) when the magnetic field is quiet, and a relatively high solar flux of, say, 175 or more. Increasing magnetic "A" indexes and declining solar flux will mark the fair (F) or poor (P) days for you. One advantage of these days and nights of equal length is the opportunity for excellent gray-line propagation along the paths of dawn and dusk around the world. Use these times to your best advantage. 73

LETTERS

From the Hamshack

Lyndon Taylor N6UCE, Yorba Linda CA As a person who does a considerable amount of reading on a variety of subjects, including amateur radio, and as one who finds himself frequently on the "opposite side" of most modern opinions of social, education, and political "truth," I want you to know how much I appreciate your columns in *73*. I say this not because you generally mirror my opinions, but because of the clarity of your presentations and your obvious conviction about what you are saying! Case in point: The December 1990 issue, where you discuss both the ARRL and the joys of being an entrepreneur. In about three paragraphs, you have presented an eloquent description of the motivation of the entrepreneur, the "adventure" of pressing an idea forward, not for money, but for the personal reward of seeing an idea that you have had become an operational reality. I can't think of anything more exciting than that, and you have stated this case beautifully.

73 Magazine is certainly more than a magazine about ham radio. It is a statement about life, about enthusiasm, and about the pursuit of excellence.

In the same issue there is an absolutely superb column by David Cassidy N1GPH on "magic." David captured the essence of why many of us entered into ham radio. It *is* magic when I walk out in my back yard and see a piece of wire stretched across the sky and know that a few hours ago it allowed me to talk to a research biologist in Antarctica over 8,000 miles away. Just as it was magic when, as an 8th grade student in the late '40s, I strung together some tubes and wire and ultimately produced a functioning television set.

The rest of your magazine is loaded with good articles about radio, and numerous ads about products and services of value to the amateur. Thank you again for your excellent writings and publications.

Art Oates, Jr., K9GBN, Pekin IL Read your article reviewing the Kenwood 27A. This radio, as you said in your article, looks nice; but that is as far as it goes. The radio has no selectivity on an outside antenna. Kenwood admitted twice to me on the phone that on an outside antenna selectivity is bad, and said that all handhelds are bad that way. I told them to use the ICOM micro or Heath micro because they don't pick up paging and weather bureau 20 miles away. It is the design in their radio which gives it bad selectivity. If you had read the schematic, you would have seen the problems they have with the selectivity.

Also, you didn't mention that it has a bad overheating problem. Could that be why, as yet, they haven't come out with a quick charge and 12 volt battery? My advice—don't operate the radio too long on 12 volts or you will have more problems with the 27A. Kenwood won't say when they will come out with a 12 volt battery or quick charger.

I didn't mention a problem with the TH-27A's selectivity because I didn't experience one. I have operated the radio in many urban areas, including the RF-saturated Northeast, and I have not found the selectivity any worse than that of other HTs. Current HTs, capable of receiving a much wider frequency range than older models, do exhibit worse selectivity than previous models (such as the old IC-2AT), but this is a problem shared by all HTs. To single a Kenwood HT out for this would be grossly unfair.

The same holds true for what you call a bad overheating problem. When you operate any *modern HT at 5 W output for any length of time, you are going to get some serious heat! To imply that Kenwood's HTs are the only models to heat up at high power wouldn't be accurate. By the way, a quick charge* is *available. It is listed in the TH-27A instruction manual on page 48. Kenwood tells me that a 12 volt battery is to be released soon. . . . David N1GPH*

Sandra M. Hawley N5OLU, Houston TX I resent both the snide tone of your "Flaplet" item in the February "Never Say Die," and your inflammatory misstatements about what happened at the Houston Ham Com.

First, the "mad" ARRL officials you referred to were members of the Clear Lake Amateur Radio Club. We were at the Ham Com because the organizers of the convention had asked us, for the third consecutive year, to run the ARRL booth for them.

Second, we weren't "steamed" because we had been refused free passes for the vendor area. In fact, we had badges that gave us access to the vendor area all day. The Ham Com officials gave us those badges, as they had in previous years, because the ARRL is classified as a "vendor" at the convention.

Third, our members did not "sneak into" the paid area and get caught "red-handed" by vigilant Ham Com officials. They put on the badges, said hello to the guards, as they had earlier, and walked in with official permission, as they had earlier.

Fourth, we did not "still refuse to buy tickets." We were never told that we should buy tickets at any point. The Ham Com officials simply marched up to the CLARC members and told them (us) point-blank to get out—this desipte the fact that CLARC was there at *their* request, wearing the badges that *they* had given us!

Furthermore, our members scarcely qualify as "bullies." One of the CLARC members who was treated so rudely was the 1990 AEA Amateur Ambassador of the Year—an individual who has made, and been recognized for making, major contributions to amateur radio. The other "sneaking bully" was a long-time amateur, elmer to many in the Houston area, and father of the winner of the 1988 Hiram Percy Maxim Award.

I have enjoyed my involvement in amateur radio, and I had enjoyed helping out at the ARRL booth. It seemed a good way to return at least some of the benefits amateur radio has given me. After this mess, I find it hard to keep up my enthusiasm for the Houston amateur radio scene at a high level. And I damned sure won't be volunteering to help at the Ham Com again.

Finally, I am appalled to find such slipshod reporting in your column. Like many others, I have often enjoyed your iconoclasm and even a bit of "ARRL-bashing." Now, having been at the other end of the bashing, I must wonder how many of your previous comments have been as inaccurate and injuring as those in the "Flaplet."

Ahh, the flaplet is being fanned into a full-sized flap! Sandra, my item came solely and totally from a report put on an ARRL BBS by the members you are defending, not the Ham Com people. Rashomon! . . . Wayne

Bob Minton NU7L, Boise ID Kudos for your stand on the problems in amateur radio. Let me add a thought or two concerning American manufacturers. I just canceled my dealership yesterday with one very well-known publisher because of their poor service. They turned down a thousand dollar order just because of their all-too-typical American snotty attitude about doing business. They are not the first company I have refused to do business with because of problems.

American manufacturers are curious as to why we have a 100 billion plus trade deficit each year. I can tell them, as I deal daily with overseas and domestic importers. Manufacturers from Hong Kong and Taiwan want my business and accommodate me as much as possible; American companies are too hung up on producing balls of red tape and nonsensical corporate idiosyncrasies for me to deal with. Until Americans get back to good old-fashioned customer service instead of dreaming up new ways to stop the flow of products, the U.S.A. is going to be nothing but a consumer country.

I hope some of the people in the electronics industry read this and take a hard look at their operation. Get rid of the placid, whiney sheep you have hired as employees and give us people who can converse intelligently over the phone. And for goodness sake, hire people who can make a decision on their own without having to check with everyone from the shipping clerk to the corporate washroom attendant.

Bob, when you're right, you're right! Every book you read on how to run a successful business stresses customer service. But getting this message through to employees can be almost impossible. We need a revolution in our whole American educational system. How are we going to teach youngsters who are given supermarket toys that break within minutes about quality? How are we going to teach Americans, who happily buy Detroit cars, to even understand the concept of quality? . . . Wayne

T.S. Rowinski KA1MDA I follow your editorials very closely, and for the most part agree with all of them. I feel, though, that you are missing one major contributing factor for the decline of the American consumer electronics industry: customer service/respect. It has been my experience that the Japanese companies treat me with respect and courtesy, regardless of how small the order. The American companies, on the other hand, give me the impression that I'm keeping someone away from their coffee break!

As an example: When my five-year-old IC-2AT HT broke down, I located the defective part and called ICOM. In no time, I was transferred to the engineering department. I described the location and function of the part, and the engineer found the part number and gave it to me. When I called the parts department, I was informed that it fell below ICOM's minimum order amount. The woman asked me if I was sure I didn't need anything else. When I replied no, I was informed that the part would be sent to me free of charge! Three days later, the part arrived, and my 2AT was back on the air that evening.

Now let's take a look at G.E. At a hamfest, I purchased a three-year-old shortwave radio manufactured by G.E. Six months later, the BFO pot went bad. I wrote G.E. a letter and received a reply four months later stating that G.E. did not sell parts to consumers, and if I wanted my radio fixed, I would have to send it in to their repair depot. I managed to find the G.E. HELP phone number, and they gave me the name and number of a parts depot. To make a long story short, the parts depot couldn't sell me a part unless I gave them the G.E. part number, and G.E. wouldn't give me the part number unless I bought the service manual! Final tally: To obtain a 50k ohm, linear taper pot, it took 7 months, 1 letter, 5 phone calls, and $32 for the manual! I'm still waiting for the part, though. . . it's on back order.

Whose products do you think I'll buy in the future? Sure, I wish I could "buy American," but I'm not going to pay premium prices for products from manufacturers who don't want to be bothered dealing with me ten minutes after my cash is in their pockets!

Jim Blizzard AB4YC Just finished reading your "Never Say Die" column in the February issue. In it, you state: "We need to do something to revive an interest in CW. . . . The voice bands are busy and the CW bands are oddly vacant." You then ask us to count the number of CW frequencies in use.

You write this shortly after you finish telling how harmful CW is to the human body. What gives? If you, yourself, are "going to steer well clear of Morse, both receiving and transmitting," why shouldn't we?

I enjoy CW quite a bit, but after reading your column, I have decided to hang up my keyer. I am sorry to read that CW may be dangerous to my health, but I thank you for being courageous enough to publish this information.

If hams heed the warnings about CW, it seems that the CW bands will become even more deserted. Keep up the good work. . . and see you in the voice bands.

You're right, of course. But keep in mind that I've been warning against cigarettes for over 30 years, and my editorials haven't had a noticeable effect on ham smoking.

If you're interested in knowing more about the enormous complexity of cells and the electromagnetics involved, you might look for Electromagnetic Man, *by Smith and Best (1989). It's miserably written, but the information, once it's picked out, will be most disturbing for hams.*

It's interesting, too, if you're into understanding how life works, to read Origins, *by Shapiro. I've just read both books and found them fascinating.*

So we have to deal with both the real world. . . plus strive for the more ideal world, where people avoid potentially destructive forces. . . . Wayne

Manuscripts Contributions in the form of manuscripts with drawings and/or photographs are welcome and will be considered for possible publication. We can assume no responsibility for loss or damage to any material. Please enclose a stamped, self-addressed envelope with each submission. Payment for the use of any unsolicited material will be made upon publication. A premium will be paid for accepted articles that have been submitted electronically (CompuServe ppn 70310,775 or MCI Mail "WGEPUB" or GEnie address "MAG73") or on disk as an IBM-compatible ASCII file. You can also contact us at the 73 BBS at (603) 525-4438, 300 or 1200 baud, 8 data bits, no parity, one stop bit. All contributions should be directed to the *73* editorial offices. "How to Write for *73*" guidelines are available upon request. US citizens must include their social security number with submitted manuscripts.

73 Amateur Radio Today (ISSN 1052-2522) is published monthly by WGE Publishing, Inc., WGE Center, Forest Road, Hancock, New Hampshire 03449. Entire contents © 1990 by WGE Publishing, Inc. No part of this publication may be reproduced without written permission from the publisher. For Subscription Services write *73 Amateur Radio*, PO Box 58866, Boulder, CO 80322-8866, or call 1-800-289-0388. In CO call 1-303-447-9330. The subscription rate is: one year $24.97; two years $39.97. Additional postage for Canada is $7.00 plus $2.24 GST, and for other foreign countries, $19.00 surface and $37.00 airmail per year. All foreign orders must be accompanied by payment is US funds. Second class postage paid at Hancock, New Hampshire and at additional mailing offices. Canadian second class mail registration number 9566. Microfilm Edition—University Microfilm, Ann Arbor, MI 48106. Postmaster: send address changes to *73 Amateur Radio*, PO Box 58866, Boulder, CO 80322-8866.

Audit Bureau of Circulations (ABC) membership applied for.

Contract: By reading this fine print you have hereby legally bound yourself to try one new facet of amateur radio in the next 30 days. Are you on packet? If not, pick up a TNC and check it out. How about RTTY or AMTOR? You'll meet some pretty friendly hams on these modes. Even the DX will rag-chew. Have you tried microwaves? How about amateur television? When's the last time you home-brewed something? The *73* advertisers can supply you with whatever you need. . .just don't forget to tell 'em *73* sent you.

Number 2 on your Feedback card

NEVER SAY DIE

Wayne Green W2NSD/1

First UPS, Now Apple!

You've probably read about Apple asking the FCC to set aside 40 MHz for a computer communications system. Well, I predicted in an editorial that such a network would inevitably have to be developed, so this isn't any big surprise. I'd hoped that we hams would be the developers, just as we pioneered today's cellular telephone system.

But just as technology had passed UPS by with their compandered SSB dreams, which we hams tried and found seriously wanting, I suspect that the Apple people who threw this one into the FCC's input basket didn't do their technological homework. Of course we hams shouldn't be ones to talk. We're still fussing over the code, which has been technologically dead for over 40 years. Alas, even with voice communications, in this great digital age we're still hanging tough with analog. It's sadly reminiscent of our "Spark Forever" stance in the late '20s and our resistance to SSB in the late '50s.

But it seems to me that a computer company should be able to come up with something better than a technology which requires 40 MHz for intercomputer communications. Tsk. Ain't you heard about spread spectrum, kiddos? Oh well, we hams haven't either. Not really.

Oh, I agree that with the world finally moving to laptop and notepad computers, having to plug wires into 'em doesn't make sense. They should be able to access networks, hard drives, data bases, large screen displays and printers without umbilical cords. And they will. They will.

Sure, we can assign separate channels for every computer at a site and do this the brute force way. It'll be easy to build in a tiny communications module which can interface with a repeaterette within a hundred feet or so. Then these repeaters can be linked via cable, telephone or even satellites to the world. . .as well as local support systems. Ooops, there's a message just in from Compuserve. . .and another via Prodigy. I can tell by the little blinking "C" and "P" on the bottom line of my notepad computer screen. Just a second. Oh yes, some chap in India says the band is open to my area and he wants me to get on 14.210 for a QSO. Yep, there he is. . .nice signal, too.

With spread spectrum we should be able to interlace zillions of computers, all in a much smaller frequency band than 40 MHz. Our communications will be infinitely more secure, too. And since any band they set aside for the Apple corps will probably eat into the nearest ham band, we have a strong vested interest in beating Apple and the FCC back with a technological stick.

No, I don't expect you, as an individual with no real interest in the frequencies we'll probably lose, to take the time to write to Apple or the FCC and express your concern. After all, it isn't your ox that's being gored. Nor do I expect that you'll bring this up at a club meeting and ask the club secretary to write to Apple and the FCC expressing a group concern. Nor would I expect anyone visiting an Apple dealer to say anything. Nor do I expect to see much mentioned about this in ham club newsletters. Nor do I expect to see the ARRL take a leadership position on this very small matter. Nor do I expect that my expectations, which are minimal, will be exceeded.

Yes, I rail out against this and that, but please do not convince yourself that I honestly expect to see any real changes. Oh, sure, I have hopes. But I'm used to changes coming slowly.

I started pushing for a no-code ticket in 1958, as I recall. At that rate of progress, I'm not likely to live to see another major change in amateur radio. I've already used up most of my allotted three score and ten and we're talking genuine glacial-speed changes. Despite my enthusiasm for new ideas, I do have one foot rooted in the real world, so, as I revealed above, my hopes are high and my expectations are low.

Will the League sue the FCC over the no-code ticket? Maybe they should start a new campaign to get donations to fund the League lawyers in these expensive attempts to further alienate the FCC. Oh, oh. . .there I go offending the delicate sensibilities of the true ARRL believers. Darn it, I wish I'd stop doing that. There's already talk of an anti-Green League jihad for blaspheming The Faith. Make a little more room in your cave, Rushdie.

Will no-code be as bad as many negative-thinkers are saying? Of course not! Will it be as great as starry-eyed optimists are preaching? Baloney! Will it start swelling our ranks and reversing our loss of newcomers? Well, I have good news! The word is just in: A chap in Albuquerque has come aboard as a no-code Tech. Gentlemen (and YLs too), we have a new licensee. I was going to say, "Rahl," but our new ham is Hispanic, so let's say, "Ole!"

As a gourmet chef I'm known as the Kitchen Cynic (call me KC for short), so I try to keep my gullibility on short tether. Even so, there are already some rays of hope that no-code will help. Like a late flash from Silicon Valley's W6NLG saying their new VEC session pulled 57 candidates, up 170%.

K1MAN Update

As if we haven't been having enough trouble with KV4FZ and his group making a mess out of the high end of 20m, now we've got K1MAN lousing up 14,275 with endless self-congratulatory broadcasts. The FCC has tried to shut him up with official citations and fines. Apparently K1MAN has substantial resources, so he's embarked on a plan to enrich both his and the FCC's legal teams, all to the detriment of amateur radio, in order to keep his microphone open.

I guess, as long as we only have Baxter and the ARRL sending blind transmissions on our bands, we can live with losing two channels. But what if there turns out to be more hams who want to broadcast?

I can understand W1AW's broadcasts. They're desperately pushing for more *QST* subscribers, so they need to advertise in every way they can (under the guise of public service, naturally). Having met and talked with Baxter, I can understand why he's broadcasting—and willing to spend whatever it takes to continue.

I hear he's pushing hard to take over the American WARC team next year. I've been trying to think over all of the hams I've met or talked with to see if I could come up with someone who I'd like less to see representing America at WARC. I've failed so far, but I'll keep thinking.

Now, I may come across in my editorials as opinionated. I like you to think that, even though I chuckle when I get letters complaining. If I let things really bother me the way I pretend, I'd have been dead years ago. With that in mind, I want to tell you about a phone conversation I had with Baxter. Well, "conversation" isn't quite accurate.

In my entire life I don't think I've hung up on more than two or three people—and the others were insurance salesmen. With Baxter I found myself faced with a close approximation of listening to his broadcasts. Nothing I could say or even shriek stopped him. I finally gave up. He almost made me mad.

With this background you may be able to imagine my reaction when I read in a ham newsletter that Baxter was bragging that he had sent a ham delegation to Baghdad to try and work out a peaceful solution between the U.S. and Iraq with Saddam. I thought, what kind of idiot have we got here?

Efforts to corroborate that this peace mission was anything more than a figment have not borne fruit. If it's true, then Baxter put several hams into terrible jeopardy. It's also, of course, completely illegal for private citizens to deal with foreign governments on behalf of the U.S. But Baxter was mixing in with U.S.-Soviet dealings, so who knows?

The War

It's nice that the FCC hasn't put us off the air during our last three wars. I still remember hearing about Pearl Harbor during a 160m QSO that long ago Sunday on December 7th. And I remember amateur radio being closed down the next day, with W1AW going after hams who pretended not to have heard about the ban. We were off the air for four years.

I'd been retired after five busy submarine war patrols and sent back to New London to teach electronics when the war ended. That same day I got on 2m, the first band they opened, from my school lab and made several contacts. I spent many nights on a hill in the submarine base with a little home-made transceiver, talking with local hams. It was a little long-lines 1G4GT/1Q5GT rig I'd built from an article in *Radio* in 1939.

After the Korean and Vietnam wars there wasn't a lot for us hams to do. But this new war is a little different, so I see an opportunity for us to provide a real and needed post-war service.

There are hundreds of thousands of people in the U.S. with friends and families in Iraq and they're going to be frantic to find out how things are at home. The military can't possibly cope with this level of health and welfare traffic. It'll probably be months to years before the telephones are working dependably again. That kinda leaves us, doesn't it?

We're going to need some volunteers to hit the decks running, so to speak. We're going to need several ham stations to be set up in Baghdad and the other major Iraqi cities to provide the communications which will be needed. If you are interested in spending a month or two on such a project I'll see what I can organize in the way of transportation.

Continued on page 86

QRX . . .

EDITED BY LINDA RENEAU KA1UKM

The End of Packet?

Last January, eight amateur packet operators were fined $300 each in Notices of Forfeiture, and three others received Notices of Violation of Part 97, according to the Norfolk, Virginia, FCC Engineer in Charge, J. Jerry Freeman. The offending message, dated January 5, 1991, stated: "From: wa3qns@n3la.pa.usa.na (JOE); Message ID: 21035–N3LA; TO: all@allbbs; SUBJECT: Call This Number, ASAP; VOTING BY PHONE - PHONE 1-900-44-NO WAR!; Conf: mideast gulf; Coalition to Stop U.S. Intervention in the Middle East (October 20 Coalition); 36 East 12th Street, 6th Floor, NY, NY 10003; Phone (212) 254–2295; Fax (212) 979–1583; December 7, 1990—The coalition has a national '900' phone number to tell Bush 'NO WAR.' The number is 1-900-44-NO WAR (starting Dec. 16). Please use it. A record of each call, by area code and region, will be taken with the petitions to Washington. You may contact the coalition for stickers and flyers to publicize this number, plus copies of the petition for a million signatures against the war, and other organizing literature."

The original complaint was registered by U.S. Navy officer Russell P. Tjepkemal/NZ2D of Virginia Beach, who said, "This message violates the spirit of amateur radio in that it has always been considered inappropriate to use amateur radio to further political causes." NZ2D also pointed out that the message did not mention the $10 fee for calling the 900 number. FCC rules prohibit the use of amateur radio to facilitate the business affairs of any party, whether for profit or not-for-profit.

According to AMSAT President Emeritus Tom Clark W3IWI, the citations ". . . may well spell the end to much of amateur packet radio." Clark was one of those cited by the FCC. Also among the cited were N4HOG, WB0TAX, WA4ONG, WA3ZNW, KA3CNT, WA3TSW, N3LA, and WA3QNS.

This appears to be the first time that the Commission has enforced the rules against operators of packet stations who retransmit an allegedly violative bulletin originating at another station. A debate has raged for years over whether operators of intermediate stations in a packet network should be held responsible for compliance of retransmitted messages.

Sysops and users of packet BBSs are confused or furious about what to do. Here are some typical statements seen on packet systems around the country: "I must now HOLD ALL TRAFFIC through this board until I have reviewed it for my own safety. . ." "This is a VERY BAD SIGN! If this is upheld, my BBS may have to be shut down, as I cannot review every message, or even every bulletin, that passes through it." "I want to make public. . .that this BBS. . . now screens all bulletins. . ."

W3IWI aired the most extensive response. He says, "The implications of the action by the FCC's Norfolk Field Office are absolutely appalling. What is implied is that. . .every station in a store-and-forward network is responsible for the actual message CONTENT passing through each node. The BBSs were cited because their calls were in the message header 'audit trail.' The FCC's action states that each BBS SYSOP is personally responsible for the 'correctness' of all messages merely passing through his system. Here, the W3IWI mail switch handles about 10,000 messages per month automatically. There is NO WAY I can vouch for every bit that passes through!"

Another consideration, says W3IWI, is PACSAT, ". . . a flying BBS with the sysops on the ground. To screen out 'offensive' messages, a ground-based sysop has to use a radio channel to verify message CONTENT. But the FCC letter says that the very act of reading an 'offensive' message on the radio is illegal. . . the logical implication is that PACSATs must be turned off!

"A number of us have discussed such issues with responsible individuals at the FCC in Washington ever since the first fledgling days of packet radio. The signal that the FCC sent was that the sole responsibility for the CONTENT of a message lay with the ORIGINATOR. The actions of the Norfolk Office seem to indicate a new policy has been adopted which effectively kills packet radio." *TNX* W5YI Report, Vol. 13, Issue #4.

Get Ready for STS-37!

The next SAREX (Shuttle Amateur Radio EXperiment) mission is currently scheduled to lift off on April 4 at 1420 UTC. Onboard the *Atlantis* will be the first all-ham crew: Ken Cameron KB5AWP, Jay Apt N5QWL, Linda Godwin N5RAX, Steve Nagel N5RAW and Jerry Ross N5SCW. They plan to operate on voice, packet, SSTV and ATV during the five-day mission. When the crew is busy with other duties, the packet robot (similar to STS-35) should be operational. Please note that it's only necessary to receive a QSO number from the robot to qualify as a valid contact. However, it's important to send in a copy of your contact for a QSL.

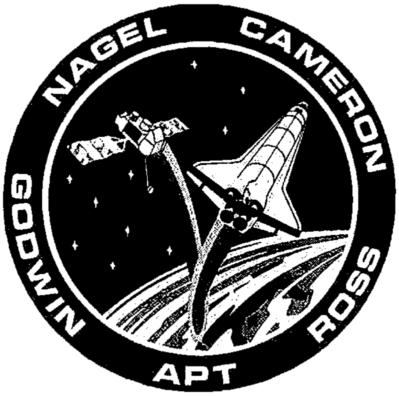

Photo A. The STS-37 crew insignia, designed by crew members. The shuttle and Gamma Ray Observatory (GRO) are connected by a large "gamma" symbolizing both the quest for gamma rays and the importance of the relationship between the manned and unmanned elements of the space program. Can you find the reference to our magazine's logo in the insignia?

The SSTV downlink should provide us with some spectacular views. Look for this mode during spacewalk activities, and in particular during the release of the Gamma Ray Observatory (GRO). During the scheduled school contacts, the astronauts plan to send down occasional SSTV pictures directly to the students.

Only a few stations, primarily at the NASA space centers, have been approved for the fast-scan ATV uplink experiment. If this is successful, it will be the first time any fast-scan video has been uplinked to any U.S. manned spacecraft.

An *Atlantis* to *Mir* contact is likely to be attempted. *Thanks to Roy Neal K6DUE, Bill Tynan W3XO, and Lou McFadin W5DID for the above information.*

FREQUENCIES TO BE USED FOR THE STS-37 SAREX MISSION

Mode:	Downlink Freq. (MHz)	Uplink Freq. (MHz)
Voice or SSTV:	145.55	144.95
		144.91 & 144.97 alternates
Packet:	145.51	144.91 MHz
		144.93 & 144.99 alternates

For SAREX updates during the mission, listen to the following transmissions:

WA3NAN (Goddard): 3.860, 7.165, 14.295, 21.395, 28.650, and 147.45 MHz.
W5RRR (Johnson Space Center): 3.850, 7.227, 14.280, 21.350, 28.495, and 146.64 MHz.
W6VIO (JPL): 14.270, 21.340, and 224.04 MHz.
K6MF (Bay area): 3.840, 7.165, and 145.58 MHz.

VE Improvements

The ARRL has made changes in its Volunteer Examiner Coordinator (VEC) program. The League will now permit its VE teams to retain up to $4.00 of the $5.25 exam fee in order to offset expenses in-

QRX...

curred locally. This should make it possible for VEs to schedule examinations more frequently and receive more publicity in their areas. The League will continue to provide its VE teams with the traditional services free of charge.

VEs may now telephone the ARRL VEC via a toll-free number: 1-800-9-ARRL-VEC (or 1-800-924-7583). Overseas VE teams should contact the ARRL VEC for information on how to access the number from their locations.

VEs who have been active in other VEC programs, and whose accreditation in another program is current, are now able to apply for "instant accreditation" as ARRL Volunteer Examiners.

By April 1, VE teams who prefer to use their own computers to generate exams will be able to do so. Also, teams preferring a multiple-choice format for Morse code exams will be permitted that option.

"As a result of the code-free Technician license, the demands on amateur radio Volunteer Examiners will be very heavy in the coming months," says ARRL Executive Vice President David Sumner K1ZZ. "We want to give our VEs the best support we can during this critical period. We also want to make sure that anyone seeking an opportunity to take an exam won't have far to look." *TNX ARRL. The above was excerpted from an MCI mail news release dated Feb. 13, 1991.*

Moonbase America

On April 16, 1991, 80 high school students will enter "Moonbase" next to Copley High School in Copley, Ohio, for a seven-day simulation. During that time, they will run their own government, eat food growing inside Moonbase, perform experiments, attend classes through a video link, and turn in their homework by FAX. All radio communication will be via amateur radio. Twenty students will be equipped with HTs, and the Communications Center in the Main Dome will house several amateur radio stations for OSCAR, packet, VHF/UHF, voice, ATV, and the low bands. Mission Control Center in the high school auditorium will be similarly equipped. Selected schools in each state will also participate in the simulation.

Special event certificates will be sent to stations contacting Moonbase from April 16 through April 22.

These students, from the Fairlawn Middle School and Copley High School, have been attending a state accredited space science class since last September. Part of their preparation included learning about amateur radio. Sixty-seven have obtained their Novice licenses, and with the new code-free Technician license, it's possible many more students will obtain licenses.

The Moonbase America project is funded by local and national corporation grants as well as local fund-raising. Training and technical support has been provided by the Cuyahoga Falls ARC, led by Rich Burgan WC8J, (216) 929-HAMS, and Mike Young WB8CXO, (216) 920-9976. For more information, you may contact Project Director Carolyn Staudt at (216) 666-5015. *Many thanks to WB8CXO for letting us know about this exciting activity.*

Go for It!

During the devastating 1964 earthquake in Anchorage, Alaska, Barbara Carter helped her husband, K6RKG (a silent key) take messages. That's how she became interested in amateur radio. "I found it rewarding to assure families that their sons and daughters were OK." She got her Novice license in 1977; her Technician and General, in 1985; her Advanced, in 1987; and finally, her amateur Extra class license in 1988. "So many people helped me," she says. Some of these people were Dave WØMEY, Nels N6AQY, Mike W6FCQ, and members of the Marin Amateur Radio Club.

Barbara was a violinist in several symphony orchestras. For 14 years, she was director of a women's chorus. Once she sang with Arthur Fiedler in one of his San Francisco Pop Concerts. Today she enjoys doing ceramics.

Her message to potential hams is: "Go for it! Amateur radio is a fascinating hobby—meeting people around the world. Sometimes you make life-long friends...I would like to see more YLs enjoying the hobby as I do." *TNX Vicki Lee Hess W6OAE/T3ØCH, a ham for 35 years herself, and a friend of WB6TPN.*

Photo C. Extra class licensee Barbara Carter WB6TPN likes to work all the bands, but especially 15 and 20 meters. She enjoys both CW and phone.

New Teaching Center

A group of local radio amateurs have established a "New Age" Electronics and Radio Communication Center (ERCC) at the Science Museum of Long Island. The museum, a 22-room mansion on 40 acres overlooking Manhasset Bay, is a non-profit organization that offers staff development workshops, consulting services to educators, and hands-on training for teachers with limited science preparation.

The ERCC, now teaching Novice classes, will expand its program to hands-on training in radio communications, computers, satellite operation, packet, ATV, RTTY, and other developments.

The "Antique Radio and Electronic Section," ERCC's recent addition, are viewed by the many museum visitors. Names of the donors are attached to all items. If you wish to donate equipment, new or old, you can write the ERCC at: Science Museum of Long Island, Attention: ERCC, 1526 N. Plandome Road, Manhasset NY 11030.

Members from the Long Island QCWA, Chapter 81, spearheaded ERCC, with help from members of the LIMARC, Nassau, and Suffolk radio clubs. The Committee for the ERCC consists of: Ed W2KPQ, Mike W2KO, Sid K2LJH, Alex AI2Q, Kate AE2Z, Milt W2ERJ, Bill KA2OVR, and Herman W2TLC. See Photo B. You may contact any of the committee for additional information. *TNX Michael J. Orofino W2KO.*

Artificial RF Ground

Maximize your antenna's efficiency.

by J. Frank Brumbaugh KB4ZGC

The ideal RF ground is having your station equipment mounted in and thoroughly grounded to a metal tub floating in salt water. Ham stations in boats approach this ideal, but the rest of us usually have to settle for considerably less efficient RF grounds. The many hams living in high-rise apartments and condos, even those with their stations on the ground floor of the typical house, have station ground leads many feet long between the equipment and actual ground. While this provides the DC ground necessary for safety, it is seldom an efficient RF ground on all the bands that you normally work.

For instance, many hams consider a few feet of wire or braid run to a nearby eight-foot ground stake a good solid ground. But—eight feet of wire is about a quarter wave on 10 meters, and presents a high impedance at the transceiver/transmitter chassis when the other end is connected to the ground stake or other good DC ground on 10 meters. This is not an RF ground at all, and the chassis will be "hot." If the mike tingles your lips, or if your fingers get "bit" by the setscrews in the knobs, you know you do not have a good RF ground, and you must do something about it.

Any length of wire or braid between your transmitter/transceiver chassis and actual earth ground presents an impedance which raises the chassis above ground for RF. Because ground connections are a part of your antenna system, impedance in the ground lead reduces the efficiency of your antenna system.

A Better Ground

To correct this problem, you can force a low impedance at the transmitter/transceiver chassis by shunting the station DC ground with a wire an electrical quarter wavelength long, open at the far end. Connect the other end to the transmitter/transceiver chassis, with the wire snaked on the floor along the shack wall. This quarter-wave "transformer" exhibits a very high impedance at its open end and reflects a very low—theoretically zero—impedance where it connects to the chassis. This provides a very good RF ground at the frequency at which the wire is a quarter wavelength in length. However, the RF impedance at the chassis, while low, will vary from one end of the band to the other, and is most effective only at the design frequency.

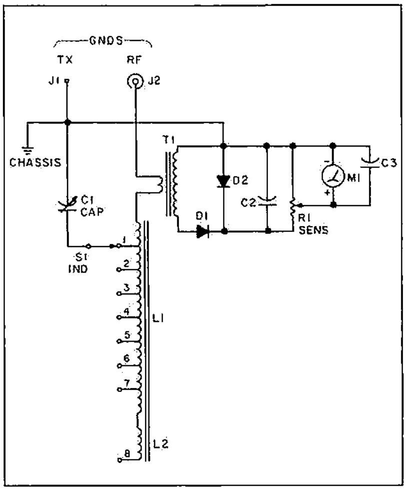

Figure 1. The artificial RF ground.

An eight-foot piece of wire connected to the chassis for an RF ground on 10 meters may be easy to hide, but what if you prefer to work 80 meters? Or even worse, if you like to work all the HF bands? You would need one or more quarter-wavelength wires for each band you normally use—and this can present problems. Few XYLs will tolerate a rat's nest of wires all over the floor, especially if the ham station is not located in a room by itself.

The Artificial RF Ground

This instrument is my solution to the problem of getting a low impedance RF ground on the bands I operate. My station consists of three monoband transceivers running 10 to 25 watts on the 10, 15 and 40 meter bands. It is located on the second floor of a frame house, in my bedroom. (Actually, my bed is in the shack!) My DC ground—a copper water pipe in the bathroom—is 34 feet from the station equipment, and an unknown number of feet from the bath to Mother Earth. I used to use open-ended quarter wavelength wires draped on the floor along the wall for RF grounds, but my cat insisted on dragging them all over the floor in a tangled mess. This made a different approach to RF grounding a virtual necessity.

Circuit Description

The Artificial RF Ground schematic is illustrated in Figure 1. A series circuit, consisting of C1, L1 and L2, is connected between the transmitter/transceiver chassis and a short length of wire which is open on the far end. The chassis, of course, is connected to your DC ground for safety reasons. This series circuit is capable of resonating in all bands between 40 and 10 meters, thus providing a low impedance ground for RF at the transceiver chassis. Current flowing in this series circuit is sampled between C1 and L1 by the primary of T1, and its level monitored on the meter M1. When the series circuit is tuned to resonance as indicated by a peak meter indication, the transmitter chassis is at ground potential for RF.

Theory of Operation

A series circuit consisting of capacity and inductance presents a very low impedance at its resonant frequency. When the transmitter is keyed (on CW, FM or AM) and the chassis is not at RF ground potential, a current will flow in the series circuit of C1, L1/L2 as determined by the position of S1 and C1, and when resonance at the transmitter frequency is achieved, this current will be at maximum. Switch S1 lets you insert varying amounts of inductance in series with C1, depending upon

the frequency in use.

The primary of T1, a step-up transformer, is connected between C1 and LI where the highest current is available. RF current flowing in the series circuit can be sampled, stepped up in the secondary of T1, then detected by voltage doubler diodes D1 and D2, filtered by C2, and applied to the sensitivity potentiometer, R1. The DC voltage across R1 is directed to meter M1, which is bypassed by C3 to eliminate any RF from the meter. M1 will show a peak indication when the series circuit is tuned to resonance at the transmitter frequency.

At this point the transmitter chassis is at ground potential for RF. To ensure the best possible ground, use the shortest possible piece of braid or wire to connect J1 to the transmitter chassis.

Because a series circuit presents an extremely low impedance at resonance, this combination of C1 and L1/L2 and the length of wire which is connected to J2 forms a very low impedance RF ground which is electrically an odd multiple of a quarter wavelength at the operating frequency.

Parts List

C1	365 pF variable capacitor, broadcast radio type
C2, C3	0.01 or 0.02 µF disc capacitor
D1, D2	1N914, 1N4148 or equivalent silicon diode
J1, J2	Banana, pin, RCA jack, etc. (J2 is insulated from chassis.)
L1	36 turns No. 26 AWG e.c. wire on T68-2; tapped at 4, 8, 12, 16, 20, 24 and 28 turns from T1 end
L2	13 turns No. 22 AWG e.c. wire on T68-3 core
M1	100 to 200 µA DC meter
R1	10k linear potentiometer
S1	Wafer switch, 1 pole, 8 positions
T1	36 turns No. 26 AWG e.c. wire on T68-2 core; primary 1 to 3 turns insulated hookup wire

Suppliers

Amidon Associates, P.O. Box 956, Torrance CA 90508. (213) 763-5770. (Toroids.)

Fair Radio Sales, 1016 E. Eureka, Box 1105, Lima OH 45802. (419) 227-6573. (365 pF variable capacitor.)

Radiokit, P.O. Box 973, Pelham NH 03076. (603) 437-2722. (Toroids and 365 pF variable capacitor.)

Construction

This instrument should be constructed in a metal cabinet or box such as the Radio Shack 276-238, which measures 5½" x 3" x 2⅛". Tuning capacitor C1 is a standard broadcast radio capacitor with a maximum capacity of approximately 365 pF. If you don't have one in your junk box, they are available from Fair Radio Sales (P.O. Box 1105, Lima OH 45802) and other mail order dealers. Plate spacing is not a problem because of the high current/low voltage characteristics of a series circuit. Toroids for LI, L2 and T1 are available from Amidon Associates (12033 Otsego St., North Hollywood CA 91607) and other mail order dealers. Meter M1 can be any of the small surplus tuning meters with a full scale reading of 100 or 200 µA.

Most of the parts for this invaluable addition to your operating position can be found in your junk box with a little help from flea markets or other hams. I had to buy the aluminum box from Radio Shack ($2.49), but all the rest of the parts came from my junk box. Even if you have to buy all new (surplus) parts, the total cost should not exceed $10. This is a cheap price to pay for knowing your station is properly grounded for RF as well as DC, and your antenna installation is operating at peak efficiency.

Operation

Connect the shortest possible length of braid (preferred) or wire from J1 to the ground post on your transmitter/transceiver chassis. This chassis must, of course, also be connected to your station DC ground. Then attach a wire 10 or 12 feet long to J2, leaving the far end open. Be sure to tape up the open end of this wire so no one, including children or pets, can touch the bare end while your station is on the air. There will be a high RF voltage present at this end of the wire when transmitting. Dress this wire on the floor along the wall behind your operating position, or under the carpet if you have a fancy shack.

Tune up your rig on any chosen band. Then, with a constant carrier output—5 to 20 watts output will be sufficient—tune C1 (CAP) and SI (IND) for a peak indication on meter M1. There may be more than one position of S1 which works. Choose the position that provides the highest peak meter indication. Use the sensitivity potentiometer R1 to keep the needle on the meter scale.

Each amateur radio installation is unique. No two are exactly alike. At my station, position 8 of S1 is used to tune 30 and 40 meters. The higher bands use various taps selected by SI, providing less inductance. If you find that you have a meter indication on 10 meters, but it will not peak at minimum positions of SI and CI, shorten the wire connected to J2. If the same thing occurs on 40 meters at position 8 and maximum position of C1, lengthen the wire connected to J2. If you wish to operate 80/75 meters, either add a much longer wire to J2, or ignore the problem. This instrument is designed to provide an excellent, low impedance RF ground on those frequency bands where such a ground is most important—40 through 10 meters. Most ham stations operating on 80/75 meters already have a good RF ground because of the long wavelength and the relatively short DC ground lead to earth.

When you achieve a peak indication on the meter, the cabinet of the Artificial RF Ground is at ground potential for RF. If the length of braid or wire between J1 and your transmitter chassis is short, it too is at RF ground potential. Thus, you will have an excellent RF ground.

On some frequencies you may find that you can get a very low indication, or nothing, on the meter. If this occurs—congratulations! You already have an excellent RF ground on that frequency.

Caution

Although J1 and the chassis of the Artificial RF Ground are both at DC ground and connected directly to your transmitter chassis, it may sometimes be above ground for RF, especially while tuning for a peak on the meter. Touching the metal cabinet of this instrument may cause errors in meter indications. There is no danger involved but, by touching the metal cabinet, you are effectively placing your body in parallel with the series circuit, detuning it, and preventing a proper indication of resonance on the meter.

It's Worth the Work

Use of the Artificial RF Ground does more than please your rig. It will also eliminate any television interference that is not a result of harmonics or stray rectification. This will also please XYLs and close neighbors, a matter of importance to many hams, especially those in apartments or condominiums. Before I designed and installed this instrument, and operating at 10 watts PEP, my signals eliminated video and distorted the audio on several television sets in the house, as well as in a few surrounding houses, even though my rigs are clean and all the connections are solid in the antenna system. When installed and tuned to resonance, the Artificial RF Ground totally eliminated all TVI (we are served by a Cable system here), even on a 12-year-old color set sitting in the shack beside the rigs. Although fundamental overload may still be a problem for high power ham installations, using the Artificial RF Ground should eliminate all other sources of TVI, especially in Cable TV installations. 73

You may contact J. Frank Brumbaugh KB4ZGC at 82 Liddell St., Buffalo NY 14212-1824.

The ESV Mod Quad

Inexpensive performer for any band from 50 through 1296 MHz.

by Martin Beck WB0ESV

Because the idea of once again working DX on 6 meters appealed to me, I began searching for a method of building a really good antenna system. I prefer the quad, but in the past that ended up being expensive. This time, I decided I'd see what I could do using my favorite material: Acrylite™, a tough, clear plastic formulated for use with a chemical known as I.P.S. Weld-on #4.

The Mod Quad has some particularly desirable features. There is absolutely no metal employed in the spider assembly to skew the pattern. Even the boom is nonmetallic. The only tools you need to construct this quad are a measuring tape, a drill, and a saw. Once the materials are assembled, each quad element can be put together in one hour. No special skills are required, making this antenna an easy project for anyone. It's the least expensive antenna to build that I have seen to date.

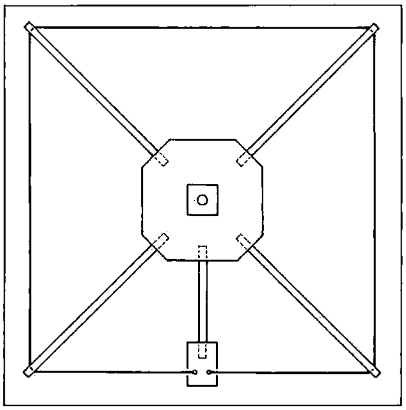

Figure 1. The ESV Mod Quad driven element.

Plastic Welding

In the plastic industry, the term "welding" means something entirely different from what it means in regard to working with metals. To illustrate: Let's say we place two clean, dry pieces of Acrylite together, and apply a couple of drops of Weld-on #4 at the edges of the junction. What happens? The chemical literally flows into the joint through capillary action. Once inside, it dissolves both surfaces, and the surfaces merge, becoming one. This is not a glued joint; the two pieces of Acrylite are now as much a single piece as if they had been originally cast that way.

Allowed to set overnight, the joint has twice the strength of one of the original two pieces.

The Spider Support

Make the spider supports by cutting out 10" by 10" squares of ½ inch thick Acrylite sheet (see Figure 2 and Table 1). If the ½ inch material is too expensive or unavailable in your area, just glue two squares of ¼ inch sheet together. For 6m and 2m, I like to glue enough squares together to make a 1 inch thick support (you can get away with ½ inch thick material as long as you beef up the corners to 1 inch, as shown in Figure 2). For 220 MHz and above, the ½ inch thick plate will work just fine, although it's best to trim it down to a 3" by 3" square (again, the corners need to be padded up to 1 inch, as in Figure 2).

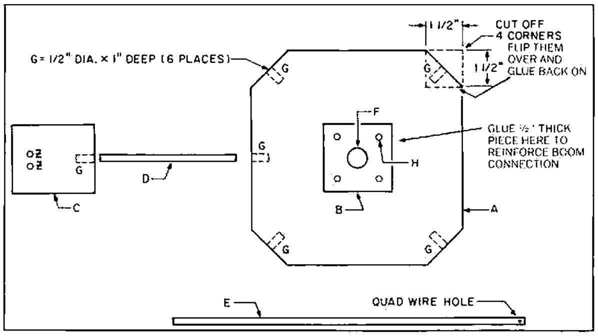

Figure 2. Details of the spider support arm. See Table 1.

Drill ½ inch holes into the edge of the support plate at the places marked 'G' on Figure 2. Insert a spreader arm (½ inch O.D. tubing or rod) into these holes and weld it (see Figure 1). Repeat this three times, and you have the ultimate quad spider—no metal, no mess. And it only takes a few minutes. Piece 'B' is used to beef up the main support plate 'A' where the boom joint is made. It's optional for 220 MHz and above. First drill four 1/16" holes in piece B (don't drill through the 'A' plate) to facilitate getting the welding chemical through to the 'A-B' surfaces. Glue piece 'B' onto the main square (6m and 2m quads). After everything is dry, drill a 1" hole in the center of the assembly to mount onto the boom (½ inch boom material can be used for 420 MHz and higher). Note that the arm labelled 'D' and the plate labelled 'C' are used on the driven element to support the coax attachment point.

The spider's center plate is joined to the 1" diameter Acrylite rod (the boom) by the same welding technique as above (see Figure 4). The boom should be carefully marked (I use a piece of masking tape) for element positioning and spacing, because once you've welded it—that's it!

Figures 1 and 5 include feedpoint construction, but of course, that is not needed for the reflector and directors. Also, you can have more than four elements by merely joining more 1" Acrylite joints, as shown in Figure 3, for a longer boom. The 0.2λ spacing can

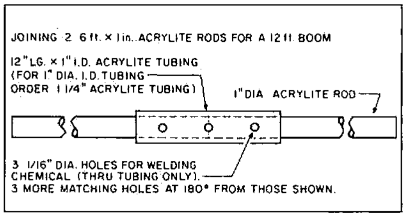

Figure 3. A small (glass only) syringe is handy for inserting the chemical into 1/16" holes. If you use a glass eyedropper, don't get the chemical in the bulb—it's plastic-based! Two to four drops per hole is ample. Allow 20 minutes set-time, then turn the assembly over and put the chemical in the three holes on the opposite side. Again, wait 20 minutes before disturbing the joint. Let it set overnight.

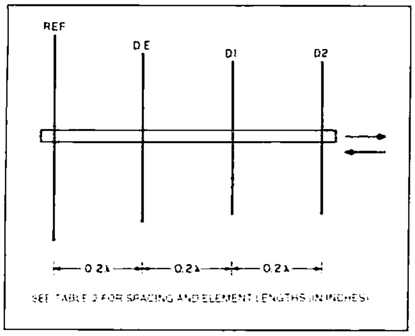

Figure 4. See Table 2 for spacing and element lengths in inches.

Table 1. The ESV Mod Quad Dimensions for 6m
Refer to Figure 2.

A	10" x 10" x 1" Acrylite sheet
B	4" x 4" x 1" Acrylite sheet. Drill four 1/16" holes for entry of Weld-on #4.
C	4" x 4" x 1" Acrylite sheet. Drill two holes for 6-32 bolts for feedpoint.
D	½" dia. x 22"L Acrylite rod or tube
E	½" dia. x 40"L Acrylite rod or tube. Cut four for spider arms.
F	1" hole through A and B for 1" Acrylite rod boom.

Note: Weld A and B together before drilling 1" boom hole.

G	1" deep x ½" dia. holes
H	1/16" holes
Z	Holes for feedpoint.

Note: The quad loop wire attachment hole on the spreader arm 'E' can be calculated from the following formula:

E (inches) = $\sqrt{(\text{Element Length}/4)^2/2}$. *(See Table 2 for Element Lengths).*

This distance is measured from the center of the boom. Make the length of your spreader arms an inch or so longer than this measurement.

also be used with a small two or three element antenna.

What do you do if by some weird circumstance you have a broken spider arm? Simple: Cut it off at the plate edge, redrill the hole, and weld in a new one! If you were to get two elements welded onto the boom with incorrect spacing, you could simply saw the boom in half between the elements, slip the sawed ends into a piece of 1" I.D. Acrylite tube, adjust the spacing—and, yes—weld the new joints in place. You can also use this method to increase the boom length beyond 6 feet (see Figure 3).

Acrylite is not expensive. Even with that latter term being relative, I feel the money is well within most hams' pocketbooks. And it's a strong material. Last year, a 116 mph wind storm broke all of my metal antennas, but not the Mod Quad. A friend reminded me of the Oriental tale of the resilient bamboo shoot that bent in the storm and sprang back, while the mighty but rigid oak was snapped. When buffeted by the wind, the Mod Quad does display a small amount of springiness.

Performance

The Mod Quad's gain is around 10 dBd. Properly spaced, a box of four quads makes a very potent system with a clean pattern. Since this quad is lightweight, it could be an outstanding antenna for Field Day. A simple TV rotor handles it easily.

While the spacing of 0.2λ gives excellent performance, you can play around with other spacings and possibly squeeze out a bit more gain. However, if you use the 0.2λ spacing, I have done all the element length and spacing for you. Refer to Table 2. The SWR is below 1.2:1 across 1 MHz, so this table is merely for the perfectionist. Most of the popular frequencies are listed. Many deadly serious DXers use 6 meters as their liaison band, but to avoid QRM, they stay higher up in the band. I computed the elements' sizes for that area as well.

Table 2. ESV Mod Quad and Delta Beam Element Lengths and Spacings

MHz	Sp."	Ref."	D.E."	D1", D2"
50.1	47.00	246.70	240.70	233.50
51.0	46.30	242.30	236.40	229.40
53.5	44.00	231.00	225.40	218.70
144.2	16.38	85.71	83.63	81.13
144.5	16.34	85.54	83.46	80.97
146.0	16.18	84.66	82.60	80.14
147.0	16.07	84.08	82.04	79.59
221.5	10.66	55.80	54.45	52.82
223.0	10.59	55.43	54.08	52.47
432.1	5.47	28.60	27.91	27.08
440.0	5.37	28.09	27.41	26.59
449.0	5.26	27.53	26.86	26.06
903.2	2.62	13.68	13.35	12.95
910.0	2.60	13.58	13.25	12.86
915.0	2.58	13.51	13.18	12.79
925.0	2.55	13.36	13.04	12.65
1250.0	1.89	9.89	9.65	9.36
1296.0	1.82	9.54	9.31	9.03

Note 1: Element spacing (Sp") = 0.2λ
Note 2: Element Length Formulas:
Reflector Length (Ft.) = 1030/F (MHz)
Driven Element (Ft.) = 1005/F (MHz)
Directors (Ft.) = 975/F (MHz)

What You'll Need

With the figures and tables, construction should be a breeze. Acrylite can be obtained from your local plastics store. Call Cyro Industries at (800) 223-2976 for a distributor near you. You may be able to find enough scrap material at one of these stores to complete the whole quad. If you can't find a local outlet, you can mail order materials from Lustercraft Plastics, Inc., PO Box 17367, Wichita KS 67217. When you write, be specific about items and sizes, and be sure to enclose an SASE. The manager requests that all orders be accompanied by a money order or cashier's check.

You can buy a four-ounce can of the chemical for a little over $2. That's enough for four Mod Quads, since only a small amount is used per joint. Full instructions are printed on the can. You can apply it with a toothpick, glass syringe, eyedropper, or even a small artist's brush.

The only materials you need for the 6m Mod Quad are five 6-foot joints (standard length) of ½" diameter Acrylite tubing or rod, a 6 foot length of 1" diamater tubing or rod (6m and 2m) for the boom (a ½ inch diameter boom can be used for 220 MHz and above), and as many 10" x 10" x 1" (or ½") thick plates as desired.

This methodology is inexpensive, fast, and very easy to follow. It produces a lightweight antenna of superior design, strength, and gain. While the system shown here is geared to 6 meters, it is even better as we use it on 144, 220, and 432 MHz; for the higher you go, the lower the cost. ■

73 Book Review

by David A. Clingerman W6OAL

Practical Antenna Handbook

Practical Antenna Handbook, by Joseph J. Carr
First Edition, 1989
Tab Books
Blue Ridge Summit PA 17294-0850
(Also available from Uncle Wayne's Bookshelf)
Price Class: $22

I don't usually get terribly excited over a book, but this is one that I couldn't put down.

It starts off with a very informative introduction that every ham will appreciate. The flow of the chapters is interesting, and logical. The book leads up to construction, rather than popping it on you first thing. This way the "old pro" can thumb to what he/she wants, and the beginner can work toward the meat and learn a lot along the way.

The chapters on propagation and transmission lines set the stage for later discussions. Mr. Carr received a lot of his material, as he states, from an old army training manual (TM 11-666). "Antennas and Propagation." I used the same manual when I designed a course on radio propagation, and I consider it a classic.

The "Transmission Lines" chapter contains many no-nonsense equations, and that's really all we need to understand and construct transmission lines. My college experience with transmission lines was most grueling because, for the text, the professor suggested a Schaum Series on the subject. The second page contained every partial differential equation known to man or woman. Carr doesn't do this to us. Nowhere in the book does he show us Maxwell's equations, may they rest in peace.

I enjoyed "The Smith Chart" chapter. Carr's approach is much like that of Sol Lapatine in his book, *Electronics in Communication*, Editions I and 2, which I use as a text in another of my courses. Without an understanding of the Smith chart, stubs and matching sections become very difficult.

The practical examples and good exercises presented are akin to a self-pacing text, which I like. Carr stresses safety quite a bit throughout the book and I feel that this is good, especially now as we are learning more and more about the biological effect of radiation on the human body. His mention of ways of keeping RF out of the shack, and of where those high voltage nodes are, should be heeded by everyone.

Carr doesn't forget that some of us are townhouse and apartment dwellers, and some of us have to live with covenants. He has something for us so we can be on the air, maybe not with a 4-element all-band quad, but with something with which we can get out.

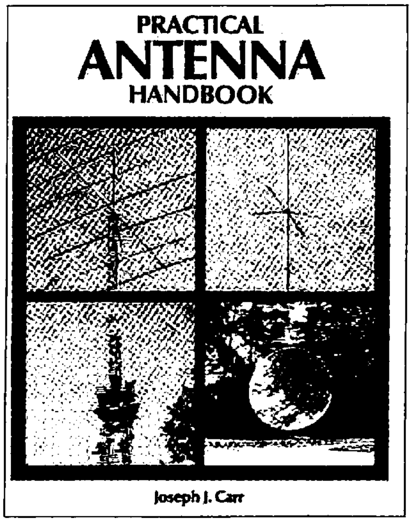

Photo. Practical Antenna Handbook.

His chapters on VHF/UHF covered the material adequately. I felt that there were a few holes, but the main points were covered. I also felt that the scanner and log periodic arrays could have had a bit more elaboration. The "Marine Radio Antennas" chapter was very good, including much attention to detail and excellent definition.

The only place where I thought more pictorials could have been helpful was the section on waveguides. I think it's easier to see TM and TE modes than to describe them. The microwave chapter fell down a little in that some substance was lacking concerning horns, loop yagis, and dipole/reflector feeds. I also feel that the section on mobile antennas could've been more extensive. Carr makes up for this with his section on matching. There were some very good hints on emergency antennas, and the measurements section had something for everyone. The construction techniques were adequate but short; the grounding section was very good. The appendices ("DXing the Smart Way," "Decibels," "Sources of Supply," and "Computer Programs for Antenna Design") were very informative, and there was plenty for the hackers.

Overall, I was impressed, and I highly recommend this book as either a reference or a text. As an engineering instructor, I plan to use this text for my course, "Practical Antenna Engineering." 73

The Happy HalfSquare™

Inexpensive gain in a compact package.

The AntennasWest HalfSquare is a simple, light, unobtrusive and inexpensive gain antenna that you can erect almost anywhere you can put a dipole. This useful antenna is rugged, neat, and plain terrific!

What kind of an antenna is a half-square? Read on.

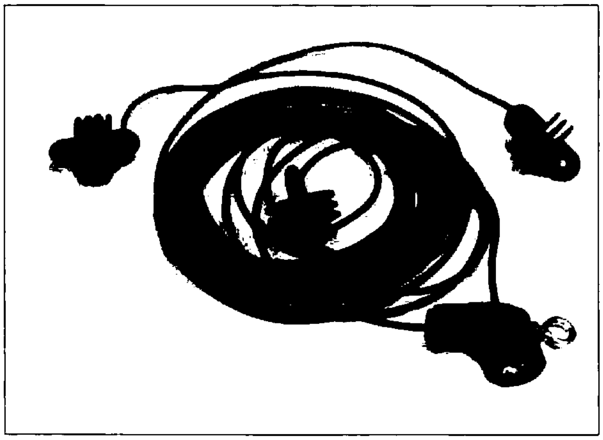

Photo. The happy HalfSquare.

Antenna Evolution

Nearly everyone has heard of the quad antenna, or the cubical quad array. The plain quad consists of a full wavelength of wire laid out in a rectangle, usually a square. A single quad loop has 1 to 2 dB of gain over a dipole, making it worth obtaining. A cubical quad array is merely two quad loops in a "space cube" figure. The array produces even more gain, something on the order of 5 to 6 dB over a half-wave dipole.

Now for the HalfSquare

The half-square antenna is just a single quad loop, opened up and stretched out to give greater gain and a lower radiation angle (see Figure 1). In the half-square configuration, that simple wavelength of wire is good for about 4 dB of gain. How does it happen? Simple. The source of the quad's gain is the separation between portions of the antenna having in-phase currents. By opening the loop and increasing the separation between the in-phase segments to a half wavelength, we more than double the gain of the quad loop. That's the secret of the half-square.

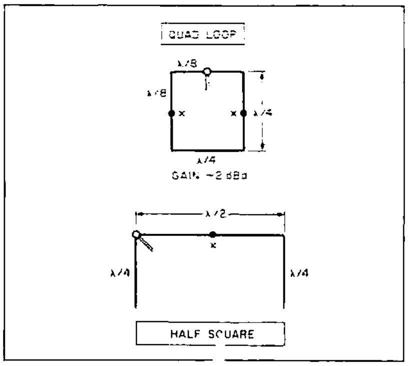

Figure 1. Cutting the quad loop and opening it out produces the HalfSquare. The half-wave spacing more than doubles the gain over the quad loop and the higher feedpoint gives a lower angle of radiation.

There's another advantage to the half-square method of using a wavelength of wire. Typically, a full-wave loop has a feedpoint impedance in excess of 100 ohms. That requires some sort of matching system. But if the half-square is fed at the right point, it has a perfect match to common 50 ohm coaxial cable.

Corner Feed

Let's return to the quad loop as a comparison. Since it is a complete loop, it will have the same impedance no matter where you feed it. But once you cut the loop and stretch it out, creating a half-square, the impedance seen by a feedline will depend on where you attach it to the wire. If you place the feedpoint at one end of the wire, the impedance will be on the order of a thousand ohms. But if you feed the half-square at a quarter wave from the end, at either of the corners, you will see an impedance of about 50 ohms—a nice match to coax without any tuner or matching transformers.

Corner feed has practical advantages, too. You can support your feedline with the antenna support itself, so you can bring the antenna closer to the house or shack. You can also use lighter supports.

To understand why corner feed works this way, think of the half-square as a pair of half-wave dipoles. Old-time antenna manuals used to feature the "quarter-up quarter-over" dipole. This consisted of a dipole with one vertical and one horizontal leg. Imagine two of these end-to-end and fed in phase.

The horizontal legs would have the same potential at their ends, so they might as well be joined. If joined, there is no need for two feedpoints; one is sufficient. The resulting antenna is the half-square. The radiation from the horizontal legs is self-canceling, but the radiation from the vertical legs is additive. The result is 4 dB of gain from an antenna that's the same length as a simple dipole (see Figure 2).

More important than the gain is the lower angle of radiation from the half-square. In fact, at the low angles that favor DX, the half-square has given me up to two S-units of signal improvement over a dipole at the same height. The drooping ends, the half-wave spacing, and the corner-feed system are the secrets of the half-square's great performance and good impedance matching.

Clever Construction

The AntennasWest HalfSquare is a delight to work with. The wire used in its construction is heavy-duty, black QuietFlex™ that resists kinking. In fact, I even tied it in a knot to test it. After untying it, I could find no visible damage or deformation. The wire's tough plastic covering makes it totally impervious to the environment. That means no noise from rain and snow, wind, or wind-born dust like we experience in Arizona. Under the insulation, the wire surface stays shiny-bright.

At the corner feedpoint there is a specially-

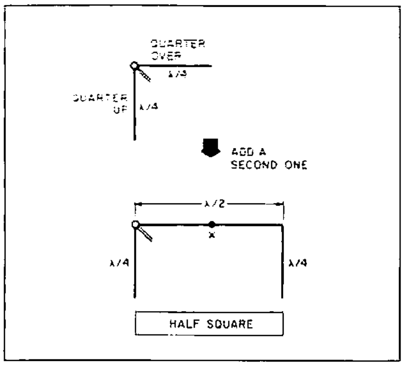

Figure 2. Evolution of the HalfSquare from a phased dipole pair. Connecting two quarter-up/quarter-over dipoles eliminates need for second feedpoint. Gain over a single dipole is on the order of 4 dB.

made housing that accepts the coaxial connector from your feedline. The connection is surrounded by a unique drip shield that keeps weather away from the mating surfaces. The housing also has a strain relief attachment point for the support rope that you use to attach the corner to the house, tree, mast, or whatever support you choose.

The two free ends of the antenna have a novel insulator that serves two purposes: The one we all know about—insulation—and the other, making tuning adjustments. A slip-and-lock arrangement permits easy adjustments of the length of the wire, which simplifies fine tuning for resonance.

AntennasWest makes HalfSquare antennas for each of the amateur bands, as well as for other bands where commercial, military, or industrial frequencies are used. Since an antenna that transmits well also receives well, it's no surprise that many HalfSquares are used for monitoring broadcasts from sensitive spots around the globe.

HalfSquares can be coiled, slipped into plastic bags with resealable tops, and carried in a suitcase. A HalfSquare needs no tuner to properly match the input/output impedance of even the most sensitive solid-state transceiver. The HalfSquare is an ideal portable DXpedition antenna.

If it's your pleasure to operate on more than one band (as most of us do), don't expect the HalfSquare to act like a beam on other than the band it was cut for. But don't be surprised to find that your antenna tuner will load it easily as a random wire on many other bands. As a random wire, my 20 meter HalfSquare has given service on 75, 40, 30, 17, 15, and 12 meters.

You might want to buy a HalfSquare for each band you operate on. Or you might get a HalfSquare for the band where DX competition is the greatest, or where you have DX goals, then use a general coverage antenna, like the G5RV, for rag-chewing. Many hams that run traffic to the South Pole or maintain schedules over long paths have found the half-square more consistent in performance than beam antennas because of its lower angle of radiation.

The price of AntennasWest HalfSquares built for the 10 and 12 meter bands is $40; for the 15 and 17 meter bands, $45; for the 20 meter band, $50; for the 30 meter band, $60; and for the 40 meter band, $70. Allow $5 for shipping and handling.

Conclusions

I am very happy with my AntennasWest HalfSquare. It's got a lot going for it with neatness, "invisibility" (it doesn't attract attention from the neighbors), a rugged and weatherproof design, usable DX gain, simplicity, and instant-easy use with any transmitter. I highly recommend them! 73

Collinear for Two Meters

An inexpensive, efficient antenna.

by F.W. Lee G3YCC

In these days of black boxes, including all-singing, all-dancing multimode transceivers, the construction of antennas is one of the few worthwhile, practical options left for the radio amateur interested in 2 meters.

Two meter collinears remain one of the most popular choices for base stations, and there are many commercial designs available. However, I intend to show that for a minimal outlay and a few pleasant minutes of work, using readily to hand components, you can make an efficient antenna.

This antenna consists of two half-waves in phase with a quarter-wave matching section, or stub, allowing a good match to coaxial cable of 50 to 75 ohms (see Figure 1).

Construction

The raw materials you need are minimal and inexpensive, even if you have to buy them. But, we hope, you can find most of what you need around the garage or junk box.

First, you'll need two 39 inch long pieces of aluminum tube ½" (12.5mm) in diameter. You could salvage a TV antenna to obtain this.

Next, you need at least a 25" piece of 1¼" (29mm) PVC plumber's tubing and a length of #16 copper wire. You could cull these items from an old power transformer or, as in my case, from a length of hard-drawn copper wire left over from an HF antenna project.

The only item you'll most likely have to buy is the moulded dipole centerpiece, which is readily available at hamfests and ham shops.

Strengthen the PVC tubing by inserting a bung of wood or some other material in both ends for about 3" (75mm). It's particularly important to make rigid the end you're going to clamp to the support.

Cut a 40¼" length of #16 wire to make the quarter-wave matching stub. Solder a lug on one end of the wire and secure it under the nut or wingnut of the top element. Pull the wire 19½" (495mm) away from the attachment point while passing it along the top of the PVC tube. Then drill a small hole through the tube at this point and push the wire through. Bring the wire back along the bottom of the tube to the centerpiece, solder another tag to the end, and secure it to the bottom element. It's advisable to tape the wire to the tube as you go, to help keep the wire straight.

The dipole centerpiece supports the half-wave sections and the PVC tube by using fixing bolts. You might also use some sort of clamp to fasten the finished antenna to the mast or support. These are cheap. Brass or other metal studding can be pressed into service, too. Construction details are shown in the Figure and Photo.

Adjustments

No actual tuning is required, but you have to use the shack rig and an SWR meter to figure out the tapping points for the coaxial cable. Do this with the antenna in the clear, preferably with the full length of coaxial cable temporarily connected. Although the antenna is fairly broadband in operation, I'd recommend you adjust it with the shack transceiver set at a mid-band point.

Make adjustments with minimum power, and take care to switch the power OFF before you touch the antenna—RF hurts! A starting position of 12¼" (312mm) is given for the tapping points, but you must move both of these until minimal reflected power is shown on the SWR meter. The inner cable is tapped along the top wire, and the braid is tapped to a point opposite it on the lower wire. When you find the optimum points, solder these connections.

Now, waterproof the antenna. There are many products you can use, ranging from polyurethane varnish to bath sealant.

The antenna is ready for mounting in its permanent position on a mast or other support. You'll realize best results, of course, from an antenna mounted on a high point, such as a chimney lashing, mast or pole, using a minimum of coaxial cable.

This antenna should give years of good service for little expense, and it can be easily made in an afternoon. No specialized tools are needed. Even if all the material were bought, it's doubtful that the bill would exceed ten dollars, representing a considerable savings over any commercial vertical. The prototype cost me about half that, using materials to hand.

I'm sure you will enjoy the building experience, and you'll obtain a lot of satisfaction in having "done it yourself." 73

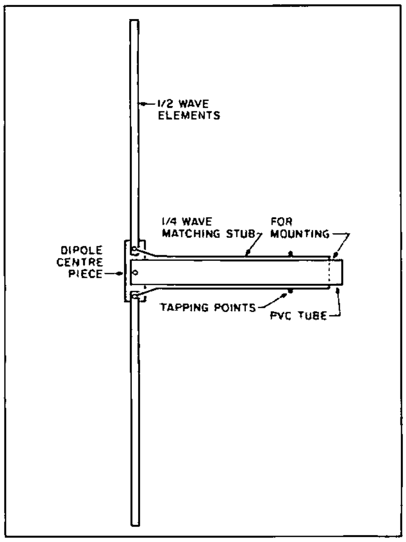

Figure. Construction details.

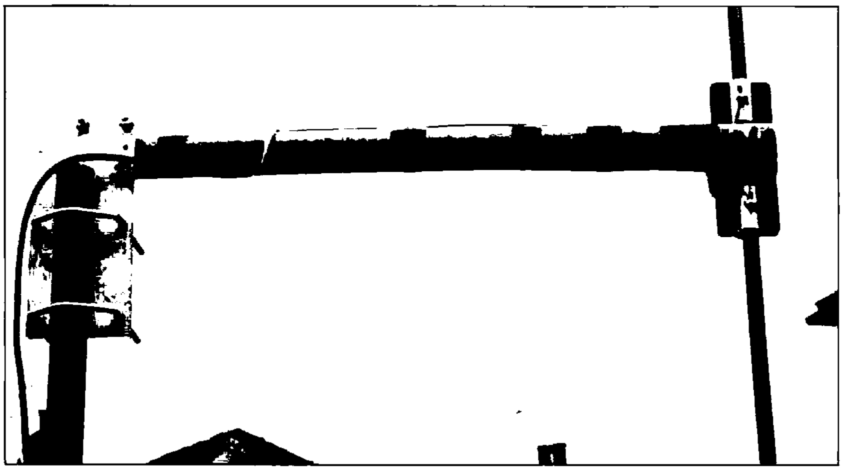

Photo. The completed collinear showing the mounting and feedpoint arrangement.

F.W. Lee may be reached at 8 Westland Road, Kirkella, Hull, England, HU10 7PJ.

Simple SupeRX

A super-small superhet for 80, 40, or 30m.

by Bruce O. Williams WA6IVC

A few years back, I developed the Simpleceiver (see the September 1986 issue of *QST*) using a ceramic 455 kHz filter. I decided to adapt that design to a receiver using more sophisticated components. The result is the Simple SupeRX described here. It uses just four 8-pin ICs, and receives CW and SSB equally well. With a reasonably well-stocked junk box, the total cost of the project is probably less than $40. How you package and tune your receiver has a big impact on cost, however. If you have to buy all of the components, plan on spending about $55.

The Design

There is nothing particularly exotic abou the design. (See Figures 1 and 2.) The NE602 is used as both a mixer and a product detector; U1 is the mixer, and the NE602 is used in a Hartley-oscillator configuration. I've found that using this type of oscillator is much simpler than the more common Colpitts type. Using a combination of subminiature monolithic capacitors, with silver-micas for the smaller values, results in an oscillator with almost no discernible drift. It is stable enough for extended SSB reception immediately after applying power.

The input voltage to both NE602s is regulated at +5V to add to the stability. U5 is a small, 100 mA voltage regulator. Since we only need about 3 or 4 mA for each NE602, there is very little stress on the regulator. The +5V is also the voltage source for gain control through the MC3340.

The Murata CFU455 series of ceramic filters is available from a few sources, although the cost of the device has increased considerably since I first started using it. There are several different versions of the CFU455, designated as A through J. The CFU455I has a −6 dB bandwidth of 2 kHz; the H version has a bandwidth of 3 kHz. Either version will work well in this application—for SSB, the H filter may be a little better.

Losses through the filter are made up by using an MC3340 variable attenuator (U2). This nomenclature is confusing, since the device is actually a variable-gain amplifier. The MC3340 is similar to some of the TV IF-amplifier chips, but it is much easier to use and offers two different ways of controlling gain through the stage. A 50k ohm variable resistor from pin 2 to ground will afford over 60 dB of attenuation. As an alternative, a positive voltage in the range of 0 to 5 volts applied to pin 2 will give the same result. This allows us to use the variable resistor for gain control, and to use a positive voltage from a transmitter keying circuit to reduce the gain through the receiver while using the receiver as a keying monitor. Although Figure 1 shows gain control through a 0 to 5 VDC source, either method can be used. The maximum gain through the MC3340 is about 16 dB—just enough to allow good headphone volume, or drive a small speaker.

Another NE602 at U3 acts as a product detector. The 455-kHz Hartley-oscillator configuration is extremely stable (on my old frequency counter, I measured less than 10 Hz drift from a cold start). The differential audio output of the product detector is routed through a Bessell filter centered at about 700 Hz, and applied to the two inputs of U4, an LM380N-8 audio amplifier chip. I found that the LM380N-8 chip, with a fixed gain of 34 dB, gives adequate audio output, but does not suffer from some of the internally generated hiss and noise that the LM386 sometimes

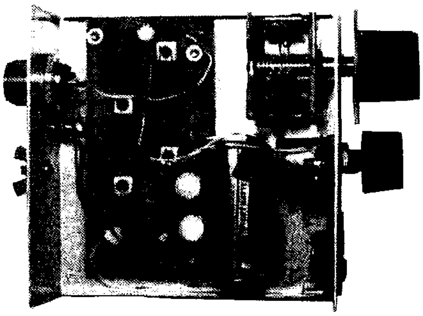

Photo A. The Simple SupeRX.

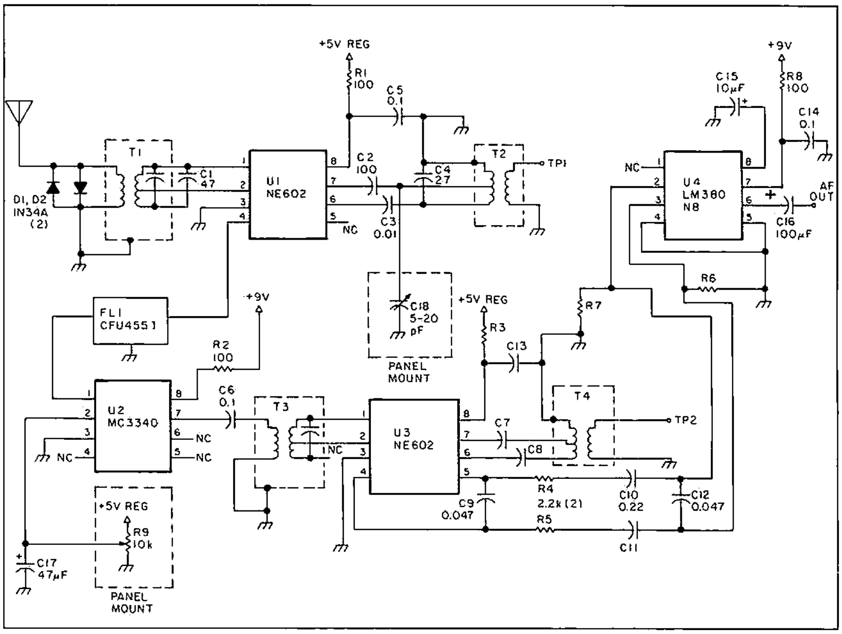

Figure 1. Schematic for the Simple SupeRX.

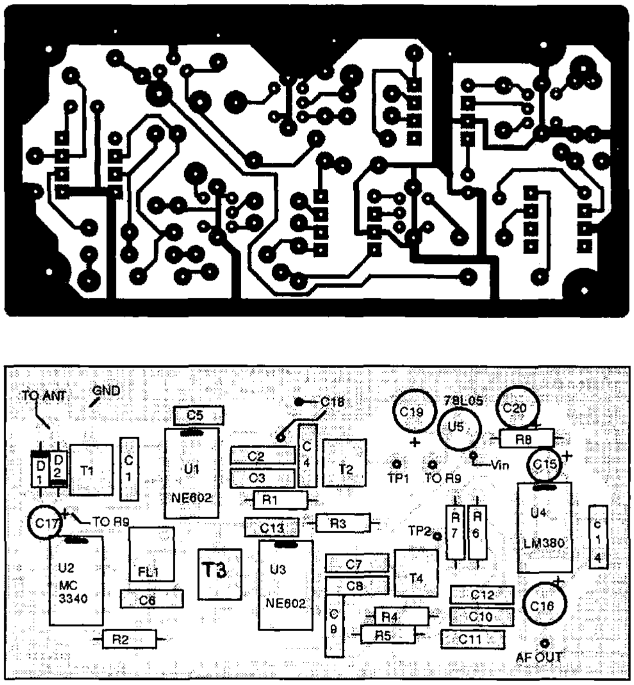

Figure 2. (a) Foil diagram, and (b) parts placement.

contributes. If you find that the LM380 doesn't have the gain you need, however, you can substitute an LM386 with just a slight change in the pin-out. The audio output can also be increased by using different values for the components in the audio filter. Changing R4 and R5 to about 1500 ohms will increase the audio output.

Construction

The table at right lists sources of parts. A printed-circuit board is available from FAR Circuits, and I am presently buying parts and assembling kits. Figure 2(a) shows the PCB layout, and Figure 2(b) shows component placement on the board. Even if you plan to build only one SupeRX, I recommend that you obtain the PC board, since it speeds construction. I've found that a receiver board can be completed in less than 2 hours.

For the prototypes, I used a product called "printed stripboard" that is available at very low cost from Dick Smith Electronics. PN H5614, the 3¾" x 3" printed stripboard, has a pattern of 0.1" wide strips that are drilled at 0.1" centers to allow mounting and soldering of parts to the board. The strips can be cut with an X-acto® knife or a special strip cutter marketed by Dick Smith to terminate the cir-

For a complete circuit board kit, you can also write to me at MXM Industries, Rt 1 Box 156-C, Smithville TX 78957. Tel. (512) 237-3906. Price for the kit, which includes the circuit board and all components is $49.95 plus $4.00 S&H. Texas residents add sales tax. Call for any hard-to-find parts.

cuit. This product is easy to use, and inexpensive, so you may not want to use a circuit board. The 40-meter prototype unit that I built used a piece of printed stripboard measuring 3⅝" x 2". I cut that board from PN H5112, a larger panel of stripboard.

If you opt for using printed stripboard, plan on spending several hours in construction. Before you start soldering IC sockets and transformers onto the printed stripboard, take time to plan the position of each major element. Use the general layout shown in Figure 2(b) for placement of the components. Taking time to plan in the beginning will be worth it later in saved time and materials. Always leave a spare hole on the strip, if you can—you may want to add some components later. Insert the various components into the board for planning, then sketch the layout. I start by locating the audio amplifier, then I work backwards through the circuit. I mount the components and solder them in the same sequence.

The choice of a cabinet is entirely up to you. Since there are only two controls, volume and tuning, a very simple package is possible. I obtained my tuning capacitor from BCD Electro. It is a small, inexpensive, single-gang unit with a built-in reduction drive. Its capacity range is about 5 to 20 pF, which gives a tuning range from 7.000 MHz to about 7.225 MHz to cover most of the 40 meter band. If you use a larger tuning capacitor, you should place a small capacitor in series with the tuning unit to reduce the range. You'll have to experiment a bit to get the right value. Of course, you could use a voltage-variable-capacitor tuning scheme with just another potentiometer on the panel, rather than a tuning capacitor.

The problem of a tuning indicator is easy to solve. You will find that for most purposes, you will be able to guess at your calibration. If you use a tuning capacitor with a built-in reduction drive, you can allow the inner 1:1 shaft to protrude a little through the front panel, and use a ¼" collet with a pointer soldered on it to indicate the received frequency with a calibrated dial pasted on the front panel. I use the ¼" insert from an old dial knob. Most old knobs have brass inserts, and you can remove the insert from the knob with a hacksaw. It is a simple matter to solder a brass indicator to the insert and install it inside the cabinet on the inner shaft. Allow just enough of the insert to protrude through the panel to give you a 1:1 tuning indicator.

Powering Up

The choice of power for the unit is easy! At high volume, the SupeRX draws about 30 mA. I use a 9 volt transistor radio battery mounted in the cabinet, with a subminiature open-circuit jack to allow hookup of an external battery or wall-transformer 9-to-12 volt supply. A 9 volt transistor battery will last for several hours, but for extended use, I recommend a larger 9-to-12 volt battery or other power source. Be forewarned that most of the cheaper wall-transformer units are designed for battery charging, and have only half-wave rectifiers with practically no filtering—they create so much hum or noise that they're unusable!

I hate winding toroids, and as a result, I've never really learned how to do it well. There are no toroids in the SupeRX! Instead, I use microminiature 10.7 MHz and 455 kHz transistor radio IF transformers. Be sure you get the smaller (7mm) "microminiature" units—their pins are just the right spacing for stripboard, and they fit the available PC board. You will have problems mounting the larger (10mm) "subminiature" transformers.

One of the "rules" for using the NE602 mixer is that input pins 1 and 2 must not be directly connected to ground. Any padding capacitors must be connected across the tuned portion of the input transformer, and the "retuned" portion isolated from ground as shown in Figure 1. If you build your unit for 30 meters, no additional padding capacitors across the transformer are required. If you are going to be on 40 or 80 meters, you will have to add capacitors across the tuned circuit in the transformer—about 47 pF for 40 meters, and about 240 pF, or more, for 80 meters. Remember to include the tuning capacitor capacitance in the calculation—that is, for 40 meters, the value of C4 should be about 27 pF since the tuning capacitor has about 20 pF, maximum.

Alignment

You need no special test equipment to align your SupeRX. There are only four adjustments, all of them to the transformers and requiring only a screwdriver. Remember to use an insulated screwdriver or tuning tool. I solder pieces of scrap component leads to the secondaries of the oscillator transformers, (marked TP1 and TP2 on the schematic), and use my frequency counter or oscilloscope for a rough calibration. If you don't have a scope or a counter, you can use your receiver for a rough calibration. Connect a short piece of hookup wire to the receiver antenna, and place the wire near to the oscillator you are checking. Remember that since we are using a 455 kHz IF, the local oscillator will be operating at 455 kHz above or below the received signal. Thus, to get a rough alignment at 7.000 MHz, you would tune your oscillator to either 6.545 or 7.455 MHz. Most ham band receivers have sufficient out-of-band range to allow you to tune the mixer oscillator.

Aligning the 455 kHz oscillator in the product detector can be done in the way described above. If you do not have a scope or counter, you can use an AM broadcast receiver. Almost all BC receivers have a 455 kHz IF. If you couple your product-detector oscillator to the BC receiver with a short piece of hookup wire loosely wound around or placed near the oscillator transformer and the BC radio IF transformers, you can tune the oscillator close to 455 kHz. Tune for a zero beat from the BC receiver. The final tuning of the BFO is accomplished with on-the-air signals.

All additional "fine tuning" is done with the SupeRX operating. The input transformer, T1, is peaked on an incoming signal, as is the 455 kHz coupling transformer, T3. The tuning of the product-detector oscillator should be done on an SSB signal—if you tune the BFO so that you can copy an LSB signal, the frequency of the oscillator is properly located near the edge of the IF passband, affording near single-signal reception—optimum for CW reception.

Conclusion

There you have it, a simple but adequate receiver for CW or SSB. I have found that although many designers bad-mouth the NE602 because of its limited dynamic range, it performs more than adequately for a simple CW receiver. It offers a lot of features that other devices don't: low cost, availability, and ease of use and alignment. I added a switchable 10 dB attenuator in the antenna input, which reduces some of the high-level signals we find on 40 meters down here in Texas. The *ARRL Handbook* gives values for different degrees of attenuation.

I have coupled my 40 meter SupeRX to a 2W crystal controlled transmitter. I use the 12 volt keyed voltage to attenuate the MC3340 gain to allow using the receiver as a keying monitor. It works OK, but I still haven't solved all of the audio thumping problems. At present, it's better to use a panel switch for changing from receive to transmit.

You can adapt any one of several excellent transmitter designs in the literature, I'm sure, to give you a small, easy-to-build QRP rig with excellent performance at minimum cost. A $1,000 rig to work CW is not at all necessary! 73

You may reach Bruce O. Williams WA6IVC at Rt. 1 Box 156-C, Smithville TX 78957.

A New Amateur Radio Magazine!

Radio Fun

Here's your chance to subscribe at a pre-publication rate to a brand new ham publication. The Premiere Issue alone should turn out to be worth several times the subscription price! The first issue of *73* is going for hundreds of dollars these days.

The pre-publication subscription price is only $9.97 for 12 issues! Not only that, but you'll get at least $25 in discount coupons as a bonus. That's right, you'll be able to save over double the subscription price when you order from Uncle Wayne's Bookshop and other *Radio Fun* supporting advertisers.

SO, WHAT'S IN IT?

If we sent you blank pages it would be a bargain, so what's the difference? Well, if you insist on looking a gift horse in the mouth, to coin a phrase, okay, here's what's in store for you.

First out, *Radio Fun* is aimed at helping newcomers to amateur radio to both get their higher class licenses and to have more fun with the tickets they have. This means we'll be running simple theory articles to help you actually learn how electronics and radio work. That's a lot better than memorizing the Q&A baloney and feeling dumb for the rest of your life. We're talking simple, so don't panic. Much of this will be the same as we'll be using to teach 5th-8th grade students about electronics and communications.

No, it isn't going to be all theory. The name is *Radio Fun*, so we'll be reviewing every kit we can get our hands on. The idea is to get you to buy, assemble and use all kinds of gadgets - some for amateur radio, some not. There's nothing like building to actually get familiar with electronics and turn book theory into practical understanding.

We'll have columns on activities which are geared to Novices and Techs. We'll be trying to get you involved with repeaters, packet radio, SSB on 2m, satellite communications, DXing on 10m, and stuff like that. We'll also be urging you to forget how much you hate the code and learn it Uncle Wayne's way so you can go on to General and Advanced tickets. How else can we get you up on 15m and 20m so you can help clean up the mess the Extras have made of those bands? We need your help...badly.

Yes, we'll be running stuff on QRP (rigs running under one watt), on hidden transmitter hunting, on how to cope with overbearing old timers at ham club meetings, on how to find parts, on how to put up simple antennas...things like that.

The Premiere Issue will be out in late April and the regular monthly issues will start in September. If you pass up this one you'll never forgive yourself. Just send your order with payment and we'll see that you get the big Premiere Issue, a wad of discount coupons, and our eternal thanks for helping a new ham publication get started. —Wayne W2NSD/1

The Carolina Windom 160

The Radio Works
Box 6159
Portsmouth VA 23703
(804) 484–0140, FAX (804) 483–1873
Price Class: $95

Work 160–10 meters with just one antenna.

Recently, I decided to become active on 160 meters. It was either that or miss out on one of my evening nets for the remainder of the winter. Remembering that this project would be used for SSB rag-chewing and not heavy-duty DX, I went over the various antenna answers that are generally thought of for 160. I eliminated some of them as requiring too much work (ground radials, etc.) or as too limiting (monoband). Then, along came the Carolina Windom 160, from The Radio Works, another version of that marvel W8GZ gave us back in 1928.

In December 1988 I reviewed the Carolina Windom standard 80–10 version. I used it for many months at my Virginia QTH, then moved it to my new QTH. With a tuner, its versatility allowed me to operate on any of the bands, including WARC, from 80 through 10 meters.

This multiband versatility was what attracted me to the 160 version of the Windom. I could use it on top band and all the other bands, too. It could act as a backup to my trusty dipole on 75, and see primary use on 40 and up. Not bad for one wire.

A "Package of Antenna"

The package the 160 comes in will surprise you. It's a plastic bag, of some weight, containing the wire elements (265 feet of #14 multistrand copper wire), a 22-foot RG-8X vertical radiator, a line isolator, and a matching unit (used like a center insulator). Now, before you ask . . . if you want, you can order the 160 with #12 stranded copper or copper-weld wire. In locations prone to high winds, the latter may be a prudent choice, but my 160 has experienced winds in excess of 75 mph and suffered no failures.

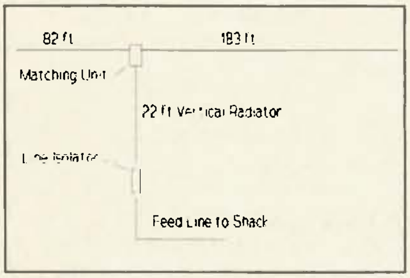

Figure 1. Diagram of the Carolina Windom 160.

Photo A. The Carolina Windom 160 package, unassembled.

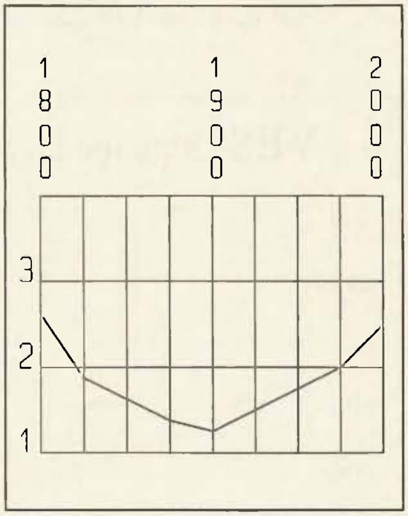

Figure 2. SWR plot of the Windom on 160 meters.

Installation

I installed the 160 in a drooping dipole manner: the highest point at 48', with the ends dropping down to about 20'. Keeping the ends

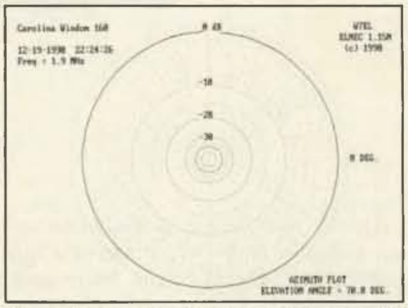

Figure 3. Azimuth plot of the Windom on 160 meters (using ELNEC 1.15M).

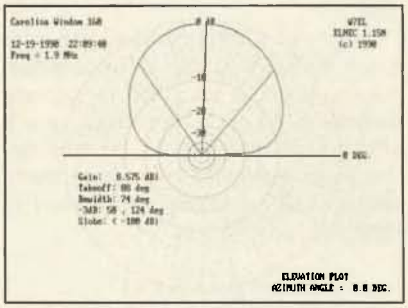

Figure 4. Elevation plot of the Windom on 160 meters.

in the air avoids possible contact with unauthorized creatures (deer, cows, neighbor's kids, etc.). The 160 is supported about 15 feet from the matching unit (center insulator) and vertical radiator. A movable insulator is placed on the long element just for this purpose. This is to eliminate the possibility of interaction between the tower and the radiator. The line isolator is about 18 feet in the air.

Tuning

The SWR curve is gentle and I am able to operate from 1.825 MHz to 1.975 MHz without needing a tuner. On the remaining bands (80–10), the use of a tuner is mandatory. However, all bands tuned easily and appear relatively broad.

How It Works

The Windom is fed off-center. In fact, this model is fed about 50' off-center. Therefore, because an unbalanced condition exists at the feed point (the RF current is out of bal-

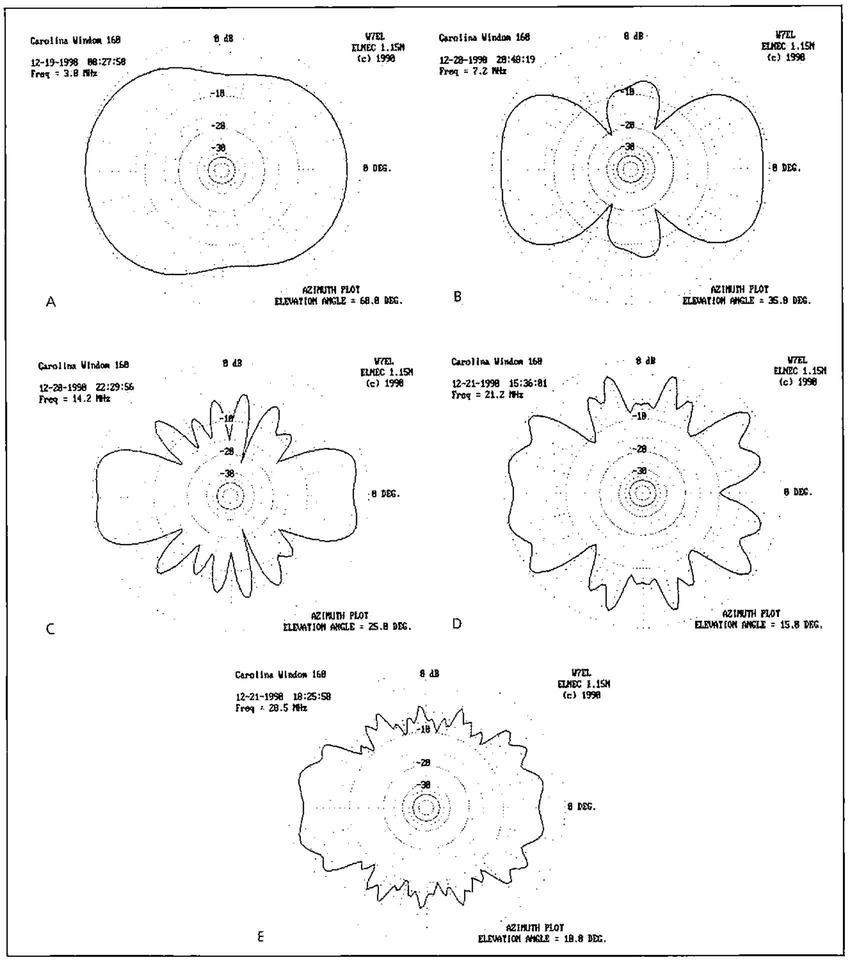

Figure 5. The Carolina Windom 160's azimuth pattern for 75m (a), 40m (b), 20m (c), 15m (d) and 10m (e). meters.

ance), the coaxial feedline will radiate. This is a planned condition and is the reason this type of Windom is so effective on the higher bands.

Naturally, you don't want to have uncontrolled radiation from the feedline. To limit it, a line isolator has been installed at the feed line end of the vertical radiator (22 feet down). From this point to the transmitter there will be no feedline radiation.

The vertical radiator, in the case of higher frequencies, gives the effect of an inverted vertical antenna. The horizontal elements continue to radiate as would be expected, giving a combination of horizontal and vertical radiation.

As with all multiband wire antennas, some gain and directivity will be attained as the frequency goes up.

On The Air

On 160 meters, I consistently work up and down the East Coast and am very pleased with the good reports I get. Of course, you must remember that with the antenna as low as it is (48'), DX will indeed be rare.

Specifications

Freq. Coverage	160–10 meters
Gain	As much as 10 dBd
Size	265' H x 22' V
Polarization	Vertical & horizontal
Feed Line	50Ω coax
Matching method	See text
Power rating	1500W recommended
Height	40' (usable at 35')

On 75 meters, for contacts under 1,500 miles, I have found that it is generally 5 to 10 dB down when compared to my 75 meter dipole at the same height. This is a general statement, as there have been exceptions to the rule. Beyond 1,500 miles, the Windom takes over, usually 5 or 10 dB ahead of the dipole.

On 40 meters, there is a slight edge with the Windom. Consistently, whether DX or local, the Windom wins over the inverted vee by about an S-unit.

On 30 meters and up, the Windom is all I have at the present time. There is no tribander or other fancy array to compare it with, but I'm very satisfied with the Windom's overall performance. I did, for a short time, compare the original Carolina Windom to the 160. Although there were a few times when one or the other seemed to be slightly ahead, there was generally no difference. End result: An improved antenna that didn't take away from the original version.

The Plots

The plots shown in Figures 3 through 7 were done with ELNEC (see my review in *73*, January 1991), and printed on a Canon Laser printer.

Nice Points

All the pre-made connections were good and solid. The vertical radiator, a piece of RG-8X coax, is pre-made with an end connector and the line isolator installed. There is a small movable insulator on the longest leg to facilitate hanging the antenna. Coax Seal comes with the antenna...use it, it'll save you grief later on down the road.

Problems

Of course, the 160 does have a few drawbacks. Specifically, its size of 265 feet. Having used wire antennas in many difficult and small installations, I can assure you that some bending of the end elements is quite acceptable. Signal degradation will be negligible, unless you actually fold the wires back on themselves. So don't be daunted by restrictive lot sizes.

Final Remarks

Would I recommend it? Yes, the Carolina Windom 160 is a really good all-around antenna that works well on the lower bands and exhibits gain and directivity on the upper bands. Due to the vertical radiator, it is a step ahead of the typical multiband wire antenna, as seen in the plots. The size is somewhat formidable, but the Carolina Windom 160 is a single antenna that does it all from local 160/75 round tables to 10 meter DX. 73

Ameritron's AL-811 Linear Amplifier

Get the real thing at the right price.

Ameritron
921 Louisville Road
Starkville MS 39759
Tel. (601) 323-9715
Price Class: $599

In the world of linear amplifiers, only one factor seems to be emphasized: cost. The higher the cost, the better the amplifier. And the better the amplifier, the better the signal. Hmm, the latter is an interesting premise, but not necessarily true.

The object of a linear amplifier is to increase the RF output of your station. In simple terms, to increase the talk power. When figuring power increases, you must be aware of a general understanding among radio operators—the law of decibels.

Let's take a typical 100 watt PEP exciter (the average modern transceiver output) and double the power. The new output of 200 watts is an example of 3 dB gain. This gain represents what is considered a noticeable received signal increase, attained every time the power is doubled. This, doubled to 400 watts, makes a total gain of 6 dB; 800 watts, a gain of 9 dB; 1600 watts, a gain of 12 dB. Of course, the FCC limits power out to 1500 watts, but we won't split hairs over the extra one hundred watts for this paper exercise.

You can see from the example that the greatest gains are at the lower watt end of the scale. What, you ask, does this have to do with a review of a linear amplifier? Simple economics! It is much less expensive to attain a 9 dB gain than a 12 dB gain. In fact, going from 100 watts to 800 watts will be less expensive than going from 800 to 1600 watts. The power supply can be smaller, the tube(s) cheaper, and the internal components need not be as heavy.

Today I feel it is safe to say that you will usually spend a minimum of a thousand dollars for an amplifier that produces a 9 dB gain, and twice that for the remaining 3 dB.

With the introduction of the AL-811 amplifier, it's refreshing to see a quality amplifier for under $600.

Installation

The AL-811 comes in a double box, well-designed to protect the amplifier shipped inside. This amplifier looks like an amplifier: The case is large and the controls are not the sub-mini size we are used to on our imported rigs. The two front panel meters are well-lighted and easily read. One meter displays either high voltage (HV) or plate current (Ip), the other monitors the grid current at all times. A red LED indicates key-down, and a standby switch is included on the front panel.

Inside the AL-811 you will find three 811As in a grounded grid arrangement. This is an old and well-proven tube design, originally developed for use in RF. They are capable of handling considerable abuse at the hands of hams lacking tuning expertise. In the event of failure they are readily available for about $25 each. This is considerably less than even the 3-500Z, which now goes for well over a hundred dollars.

To prepare the unit for operation, just remove the cover's screws and lift it off. Inside you will find plastic foam around the tubes and a bag containing the neatest fuse holders and fuses I've seen recently (they push in and pop out; they're not the old screw-in type). After removing these materials and checking the tubes and other components for security, I replaced the cover, installed the fuses, and hooked the amplifier up.

While inside the unit, I took note of the very nice glass epoxy circuit boards, excellent structural design, and quality of workmanship. All was top grade. Unlike many amplifiers I have examined over the years, the chassis of the AL-811 does not use the cover as an integral part of the chassis (stiffener). It is just a cover, and no more.

The RF input circuit is a very solidly built Pi-network tuned slug system. The Pi-network output circuit is of equal quality. The power transformer connections, using a buck boost winding, can be changed to accommodate 120/110/100/240/230/220 VAC, making it workable nearly anywhere.

An ALC circuit is built into the AL-811 to prevent excessive drive levels from damaging the amplifier, and to prevent the resulting RF interference it causes.

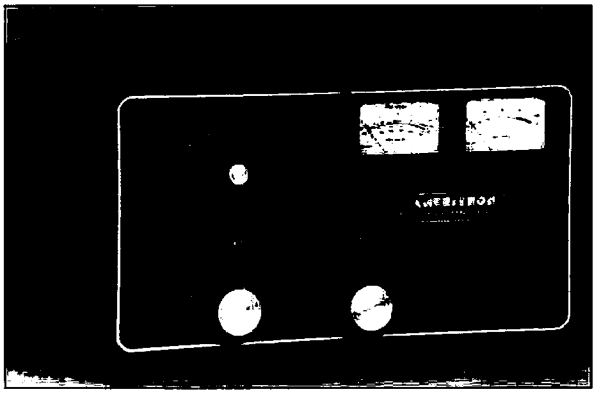

Photo A. The AL-811 covers the 160–15 meter bands.

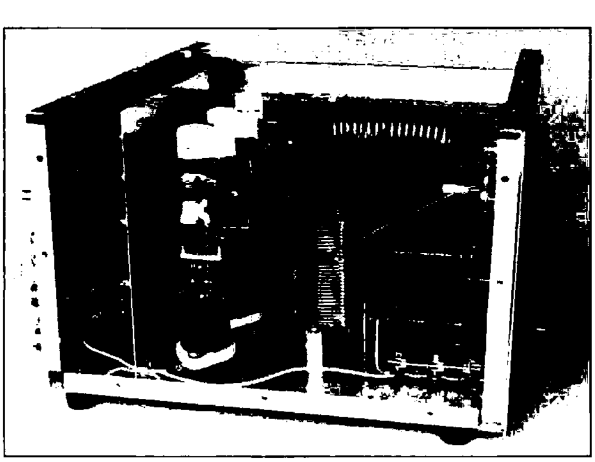

Photo B. An inside peek reveals the quality construction.

Observations

For the sake of safety, and for the edification of the many hams who have never operated anything using more than 12 VDC in the power supply, Ameritron has included internal and external labels warning of the lethal voltages present within the amplifier.

The instruction manual is short and to the point. I would advise anyone using the amplifier to read it before turning anything on. Included with the manual is a one-page generic set of instructions for tuning all linear amplifiers. This fine page should be read by all using, or contemplating using, an amplifier, as it answers many questions you might ask.

I noticed some contradictions in the manual involving input power. Depending on where you look, you might see a "never exceed" limit of

70, 85, or 100 watts. For the purposes of this evaluation I chose the latter, as that was the power mentioned in the tune-up section.

Ameritron's one-year product warranty does not appear to include the tubes. No mention of warranty on the tubes was seen.

Using the AL-811

The AL-811 comes from the factory set up for 120 VAC. As the current draw is not high (max. of 8 A), you may not need to do any extra wiring to use the amp. This will depend upon your house or shack wiring. I can tell you, however, that if you locate the amp over fifty feet away from your circuit breaker box on a #14 line, you will experience a significant voltage drop during key-down.

My recommendation for this, or any RF amplifier, is to operate it on a circuit of its own. Plug-in power bars, although nice for powering small equipment, are not satisfactory for powering an amplifier. (See the table.)

Watching the output signal on my scope, I saw no bad news. The signal never flat-topped. In getting signal reports, I switched between the AL-811 (700 watts) and my AL-80A (900 watts). In some cases I told the receiving station what I was testing, while in other cases I kept the station in the blind. There was never a time when the AL-80A was reported better than the AL-811. Reports were "no change seen," as expected.

Due to the law of decibels, as described earlier in this article, the difference of a couple of hundred watts won't be noticed at the receiving point. Of course, you could spend another thousand dollars and get a "full power" amplifier to get that last 3 dB.

The Judgment

What I liked the most about the AL-811 included the stout chassis, inexpensive tubes, quiet fan operation (my computer makes more noise), excellent internal construction, and the 12 VDC keying circuit.

My dislikes were few. It would be nice, for example, if the meters were slightly larger. Also, I found some mistakes in the manual.

Do I recommend this amplifier to other hams? Very much so! It is cost effective, something you rarely see in ham radio these days. 73

SV Products' WARC Band Yagi

Model 1824/2L—a super buy!

SV Products
4100 Fahlsing Road
Woodburn IN 46797
Tel. (219) 632-4642 evenings and weekends
Price Class: $200 plus UPS.

Adding a dedicated antenna for 17 and 12 meters is a sure way to improve your performance on these bands. Until recently, there were few beams commercially available for the WARC bands, and most operators used what they had on hand: an all-band Zepp, a G5RV, a dipole, or a random wire.

The Evolution of a Dipole

Today, several manufacturers offer yagi designs for 17 and 12 meters, and the amateur operators who use them are beginning to realize the vast difference they make. One of the first 17/12 meter beams was produced in kit form by Gary Nichols KD9SV, under the trade name of SV Products.

A well-known low-band DXer, Nichols moved to 17 meters early in the game, like many other 160 meter fans, and immediately began developing an antenna for the band. His first product was a trapped rotatable dipole, which was well-received by some of the pioneer WARC band stations.

I started out with this kit, then, when he started making the 2-element kit a little over a year ago, I bought the "add-on" reflector. Two months later, I got a note from Gary telling me he had discovered that some of the stainless fittings he had bought and shipped with the kits were corroding slightly in some applications, and he was voluntarily making them good. The next day, UPS brought me a box of all-new stainless hardware. It was a nice touch.

The 2-Element Yagi

The SV Products' 2-element yagi design features an exceptionally clean pattern, moderate gain, novel trap design, compact dimensions, and ease of assembly. It's made of high quality aluminum tubing with stainless steel hardware, and it's attractively priced at $199.95 plus UPS shipping charges.

The SV Products dual-band beam has several points which make it a good choice for the ham who wants to expand his capabilities on 12 and 17 meters. Among these is the "coaxial" trap design. The traps (two per element) are completely weatherproof, immune to fouling by bugs or dirt, and able to withstand the legal power limit with ease.

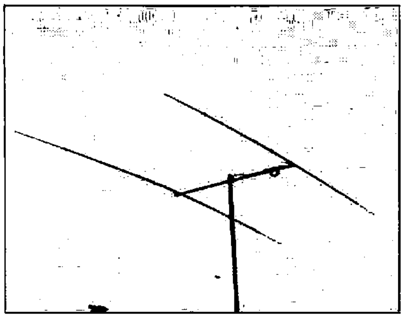

Photo. The SV Products' 1824/2L.

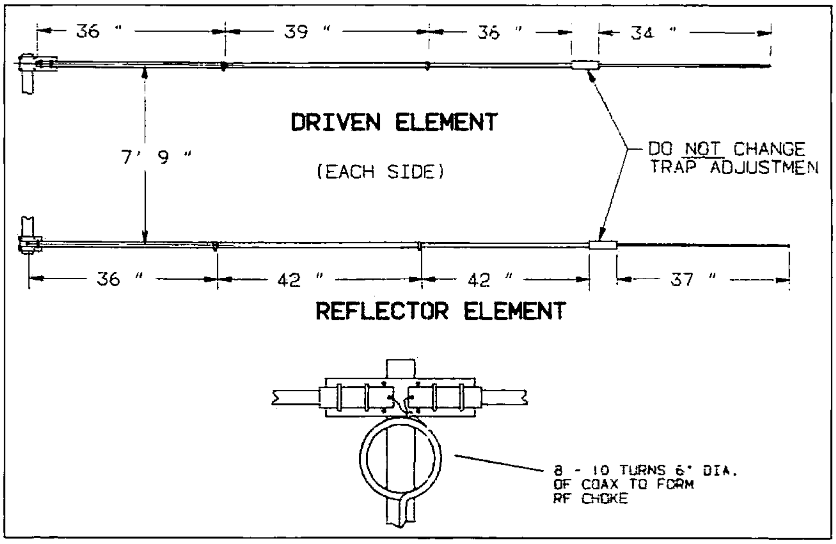

Figure 1. Element and feedpoint details.

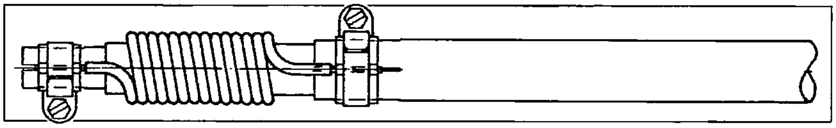

Figure 2. The coaxial trap.

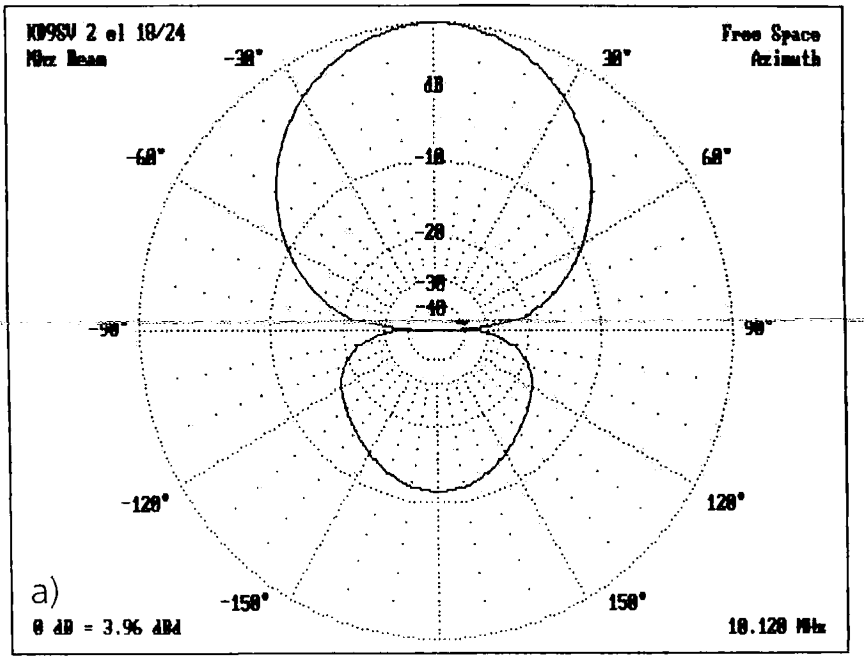
Additionally, the traps should never need any adjustment, and, unless subjected to a direct lightning hit, they ought to last forever. A more complete discussion of the design of the traps can be found in the May 1990 issue of *Ham Radio*, in an article by Nichols.

KD9SV makes no gain claims for the antenna, but after a year's experience with the beam, I can assure you that its F/S ratio is excellent, and its F/B is at least as good as the computer-derived plots (see the figures). Also, the forward gain is certainly worthwhile.

The theoretical forward gain figures for this antenna, based on the computer study, are 3.96 dB for 17 meters and 3.99 dB for 12 meters. These values are certainly borne oul by my experience with the antenna, and while they do not approach the figures you'd expect from a 4-element, wide-spaced monobander, they are surely respectable for a beam of this size.

The SV Products beam is directly fed with 52 ohm coax. The driven element is split at the feedpoint and insulated from the boom, obviating the need for a matching device. This system simplifies assembly considerably. Nichols strongly recommends a coaxial RF choke at the feedpoint. This choke is easily constructed by looping the feedline into an 8-10 turn coil about 6 inches in diameter just below the feedpoint.



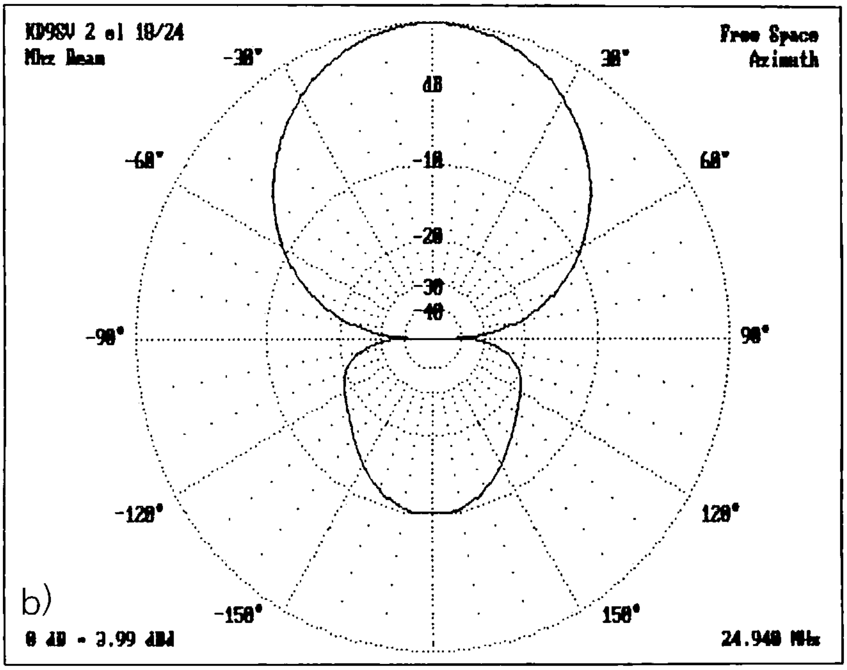


Figure 3(a). Computer plot of the azimuth pattern for 17m. (b) Azimuth plot for 12m.

Assembly, Testing, and Installation

I found construction of the antenna to be first-rate, and assembly a snap. A friend and I, working together, had the beam fully assembled and ready for testing in about an hour. The dimensional drawings provided in the package are superbly done and extremely simple to follow. No step-by-step assembly instructions come with the antenna; none are needed because of the simplicity of the design.

Nichols recommends testing the assembled beam on the ground, before you put it up on the tower. He suggests aiming it skyward, with the reflector element supported about a foot above ground, and applying enough power to check the SWR. You should see no more than a 1.5:1 SWR at this stage. The SWR will drop to about 1.2:1 when the antenna is raised to operating height.

Since the assembly dimensions are so easily followed (no fractional measurements), I simply re-checked all my figures and bypassed the ground testing phase. When placed above my tribander at 65 feet, I found my SWR figures were essentially flat over both bands at the first crack.

Now a word about the size and appearance of this beam. On the ground, the beam looks ungainly. The reflector is 26′4″ long, and the driven element is 24′6″. They are spaced just under 8 feet apart. The antenna gives the impression of being all elements and no boom. However, it is quite well-balanced, and it loses its ugly duckling appearance as soon as it goes up on the tower.

The total weight of the antenna is just 16 pounds, and it presents only 2 square feet of windloading. This makes it an ideal candidate for stacking above a moderate sized tribander. KD9SV recommends that it be stacked about eight feet above an existing array. In my case, at five feet of separation I have found no detuning effects on either the dual-bander or my existing tribander.

The boom is supplied with the kit. U-bolts that will accept a mast up to 2″ in diameter come with the kit.

Performance

No antenna review is complete without a paragraph or so on results. For each of us, the bottom line is how the antenna performs in real life.

The KD9SV beam *works*. Over the year that I've used it, it has given me absolutely trouble-free service. The reports I receive are all excellent. I enjoy DXing on 17 meters a great deal, and this beam has made the chase all the more worthwhile. There is a great deal of satisfaction in being able to break a pile-up on the first call, and this antenna has provided me with that thrill on numerous occasions.

And stateside rag-chewing is a lot more pleasant when you're not getting kicked around by QRM, too.

Because of its inherent simplicity of design, top quality compoments, ease of assembly, and high performance, the SV Products model 1824/2L beam is a highly recommended buy. 73

Pocket-Portable Seven-Band Antenna

It's cheap, easy-to-build, and effective.

by J. Frank Brumbaugh KB4ZGC

Operation during emergencies, on camping trips, or on Field Day often requires the use of less than optimum antennas. The usual wire dipole needs an antenna tuner for multiband operation, is somewhat bulky, and is subject to tangling. Separate dipoles for each band further multiply these problems. Hams living in apartments or condos who are restricted to indoor antennas especially need a better way to get on the air with an efficient antenna, but one which is not generally noticeable to the eye.

How about an antenna that covers 40 through 10 meters, is small and portable, weighs but a few ounces, is ideal for apartment or attic installation, is almost invisible when erected indoors, and can be built for $5?

The Antenna

The seven-band multiple dipole described in this article is a full-sized dipole for all bands from 40 through 10 meters. It fits in your pocket and can be erected in a few minutes. Neutral in color, it can be tacked to a wall or ceiling, ends bent as required, yet remains practically invisible to the casual visitor when used in an apartment. It is especially handy for traveling hams staying in motels.

The secret of this almost invisible antenna is the use of seven-wire flat ribbon cable. You can buy a 100-foot reel of gray ribbon cable from All Electronics Corp., P.O. Box 567, Van Nuys CA 91408 (catalog no. RCBL-7). This flat cable is less than ⅜ inch wide, making it very light and easy to erect indoors using staples or thumbtacks, or outdoors tied to trees or other supports, and equally easy to take down. With both halves rolled, it makes a package 5 inches in diameter and ¾-inch thick, easy to fit into a jacket pocket or tuck into the corner of a suitcase when traveling. The cable resists tangling because it is flat, making installation and operation much easier.

Construction

See Figure 1. Separate the seven wires for about 2 inches at one end of the cable, then strip the insulation from all seven. Twist the bared wires together and solder. This will be the feed point of one half of the antenna.

Next, measure 32 feet 8 inches from the end of the insulation at the soldered end of the cable. Cut the cable at this point. Now, repeat this entire procedure to produce another length of cable for the other half of the antenna.

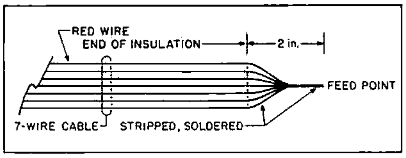

Figure 1. Feedpoint details. Strip 2 inches off of the end of the wires, twist them together and solder.

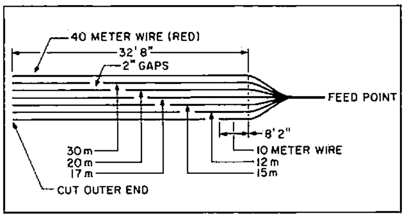

Figure 2. Construction details of the seven-band antenna. Two inch gaps are cut into the cable to isolate each resonant dipole element.

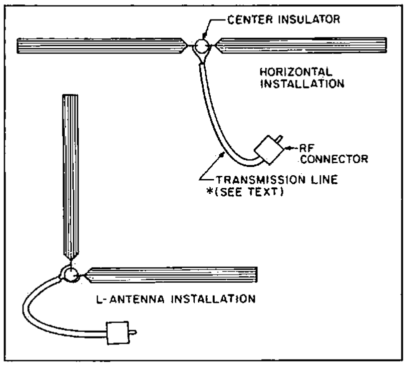

Figure 3. The completed multi-band antenna showing suggested installation configurations.

Note that the cable has the wire at one side colored red. With this wire as the 40 meter antenna, the outside gray wire across the cable will be the 10 meter antenna. Measure 8 feet 2 inches from the end of the insulation at the feedpoint. With a pair of diagonal cutters, **very carefully** cut the outside gray wire at this point, forming one half of the 10 meter antenna. Now, pull about 2 inches of the outer portion of the gray wire at the cut point loose from the cable. Cut off this short piece of wire and discard it. **Do not loosen or cut the 8-foot-2-inch wire!**

Measure 15 inches from the cut end of the 10 meter antenna on the adjacent (second) gray wire. Cut this wire carefully and remove about 2 inches of the wire towards the far end of the cable, as described above. Use a sharp knife to split the insulation between the wires on each side of the wire to be removed. This makes it easy to snip out the short length to separate the 12 meter antenna from the rest of the cable.

Measure 19 inches from the cut end of the 12 meter antenna towards the far end of the cable. Mark the third gray wire at this point. Separate and remove a 2-inch piece of wire as described above, forming the 15 meter antenna.

Measure 2 feet from the cut end of the 15 meter antenna on the fourth gray wire. Mark the wire at this point. Separate and remove a 2-inch piece of wire as described above. The fourth gray wire just prepared is the 17 meter antenna.

Measure 3 feet 6 inches from the cut end of the 17 meter antenna and mark this point on the fifth gray wire. Separate and remove a 2-inch length of wire, as above. This fifth wire is the 20 meter antenna.

Measure 6 feet 6 inches from the cut end of the 20 meter antenna, as above. Mark, cut, and discard a 2-inch length of wire from the outer part of this sixth wire. This is the 30 meter antenna.

The remaining red seventh wire is the 40 meter antenna, and is already cut to the proper length.

Now, prepare the remaining 32-foot-8-inch length of cable as just described. This forms the remaining half of the seven-band antenna.

Both lengths of cable should be identical and look like Figure 2. The 2-inch gaps in the six gray wires must be in the same places on both antenna halves. These gaps separate the outer ends of the 10-through-30 meter antennas from the unused lengths of wire in the outer portions of the cable. The wires are retained to maintain strength and flatness in the cable when the antenna is erected.

Feeding the Antenna

Depending upon how and where this antenna will be used, the center insulator attaching to the two halves at the feedpoint can be anything from a piece of string, a coat button, or even a standard ceramic or plastic antenna insulator. The transmission line for the antenna can be made of speaker wire with a clear insulation, alarm or intercom twisted pairs, the remaining, unused length of cable still on the reel, or you can use RG-8X or RG-174/U coax.

Radio Shack has a two-conductor speaker wire with clear insulation (RS 278-1301) in 50-foot rolls for $2.99. They also sell two-conductor twisted pair alarm wire (278-860) in 100-foot rolls for $5.99. However, making your transmission line from the remaining cable is cheaper, and will be less visible in indoor installations.

Making the Transmission Line

If you wish to make the transmission line from the remaining length of seven-wire cable, strip the needed length of three adjacent wires from the remaining four wires so you have two pieces of cable. The one you will use is the three-wire section.

Separate all three wires at one end of the transmission line and remove the insulation from the two outer wires for about 2 inches, depending on the length of the center insulator used at the feedpoint of the antenna. Now cut off and discard the short length of the center wire.

Only the two stripped outer wires will be used for the transmission line. They approximate a 72Ω line. The unused center wire maintains the constant spacing and provides additional strength to the transmission line.

Connect the stripped bare wires at the end of the transmission line to the bare ends of the antenna halves at the feedpoint. Solder both connections.

Prepare the other end of the transmission line in the same way, again removing the unneeded short length of the center wire. Now, solder the ends of the transmission line to an RF connector which matches the output connector on your transceiver or antenna tuner.

Erecting the Antenna

You'll find this antenna to be extremely portable. It rolls up into a nice compact package. When operating outdoors just find some cooperative trees to support the antenna and you're on-the-air.

The following are some hints for indoor installations in a motel room, apartment or condo.

The best and most inconspicuous place to mount the antenna is on the longest wall available, centered, or with the feedpoint at one corner to form a vee shape, which will give slight directivity. Whichever method is used, the antenna should be snugged up against the ceiling. The red 40 meter wire should be at the upper edge of the cable, making it less obvious. Because adults very seldom look above their own eye level, few visitors, including landlords and building managers, would even suspect the existence of your antenna. And, if you use white or clear glass or plastic coat buttons as a center insulator, your antenna will, for all practical purposes, be invisible.

Attach the antenna to the wall with office staples. They are wide enough to span the width of the cable without penetrating it. If you use thumb tacks, be sure that the metal tack does not short the actual antenna wires. If neither is available and you are in a hurry, cellophane tape used generously will probably hold the antenna up for a while. However you mount the antenna, it will be easy to strip it from the wall later. Pulling it loose will leave only tiny invisible holes as evidence.

As much as possible of the central portion of the dipole should be horizontal, but bending the ends to fit the available space will not greatly affect the operating efficiency of the antenna as long as the ends are not bent back parallel with the horizontal portion. Considering the height of the ceiling in most indoor locations, this antenna can also be used as a vertical-horizontal L-antenna, especially on 15 through 10 meters (see Figure 3). Simply tack the feedpoint in one corner of the room, roll out the horizontal leg along one wall, and tack the vertical portion at the top of the wall, and also on the ceiling if the end must be bent because of low ceiling height.

If you do not need 40 and 30 meter capability, you can shorten this antenna considerably, making it much easier to install indoors. However, it is not necessary to remove the 30 and 40 meter wires. This antenna provides full-size dipoles on all seven bands, whether you use them or not.

Performance

This antenna is not as efficient as 50-foot high individual dipoles erected outside. However, it will give a good performance in operation on all seven of the ham bands for which it is designed.

If an SWR of about 1.5:1 is acceptable—most modern transceivers will operate successfully into this high an SWR—you won't need an antenna tuner, but if there's one available you'll probably want to use it.

The transmission line will probably radiate some of the power supplied to the antenna. So what? Radiated RF goes somewhere, and it may well fill out a "blind spot" and result in contacts otherwise missed.

A dipole is not an especially directional antenna. This is particularly true when the dipole is either fairly close to ground or installed in the vicinity of hidden wires and pipes in indoor or outdoor walls of a motel room or apartment. These elements distort the free space doughnut radiation pattern shown in antenna literature. But, this project will give you a simple and effective seven-ham-band multiple dipole which is easy to build, install and use, light and portable, and at a cost of only $5, is within the budget of probably every ham. 73

Ten for 10

Build a high performance, 10 meter beam for $10.

by Michael Harris KM4UL

I have always enjoyed home-brewing ham radio equipment, and especially antenna projects, because the components are relatively inexpensive and the results are tangible. My wife says that I build and tinker more than I operate. Guilty as charged!

This article is a result of my tinkering, providing a practical example of constructing an X-beam for 10 meters. The antenna uses components commonly available in hardware stores, but it's also very inexpensive even if you have to buy all the materials. I purchased the primary components at my local hardware store for less than ten dollars.

I got into this project because I couldn't establish a schedule with Robin N7NHF in Idaho. His vertical and my delta loop weren't reliably making the trip. After discussing the matter, we decided we needed to improve our antenna situation.

Robin had both an interest and local expertise with quads, so he began his project. I remembered an interesting article, "Designing X-Beams" by Brice Anderson W9PNE in *The ARRL Antenna Compendium, Volume 1*. This article also appears in *The ARRL Handbook*, 67th edition (1990), Chapter 32, "Designing X-beams." The X-beam promised good performance and appeared to be relatively easy to construct. The article discusses design, construction, and tuning in general, but does not focus on a particular design. I picked up the ball from there and the result is an operational X-beam, a regular schedule with Robin, and this article, an explanation of how to duplicate the antenna I built. It contains construction alternatives and hints on prototyping.

Performance

The design article claims gain figures of 6 dBd and a front-to-back ratio of 15–18 dB. What I noticed was an improvement from "headphone copy" to "solid copy" during my schedules with Robin. Good enough for me!

Several hams have mentioned reading "bad things" about X-beams, frequently referring to L.A. Moxon G6XN's *HF Antennas for All Locations*, Chapter 5, "X-Beams and Slopers." These "bad things" relate to getting an acceptable pattern and a characteristically low feedpoint impedance.

The general problem of X-beam patterns was solved in Brice's design by adding the tails. These effectively prevent side lobe radiation and provide a good pattern.

Photo A. The completed X-beam.

The problem of low feedpoint impedances is common to all antennas with close-spaced elements—including yagis. The antenna exhibits a feedpoint impedance of approximately 10 ohms. This is easily matched by techniques commonly used to feed yagi antennas. I used a "Collins balun" as described by George Badger W6TC in "A New Class of Coaxial Line Transformers," *Ham Radio Magazine*, February 1980, Part 1; and Part 2, March 1980. I describe construction of a suitable transformer in this article. I highly recommend this class of coaxial baluns for all antenna work.

I have performed extensive computer modeling of this antenna using MININEC3 (J.C. Logan and J.W. Rockway, *The New MININEC, Version 3: A Mini-Numerical Electromagnetic Code*, NOSC Technical Document 938, National Technical Information Service, 1986). This modeling confirms the gain figures reported by Brice, the effectiveness of the tails, and the feedpoint impedances. The general predictions of the computer modeling have been confirmed by antenna measurements and in-service observations.

Materials

I enjoy reading articles about how somebody built this or that with some exotic material or tool they just happened to have around,

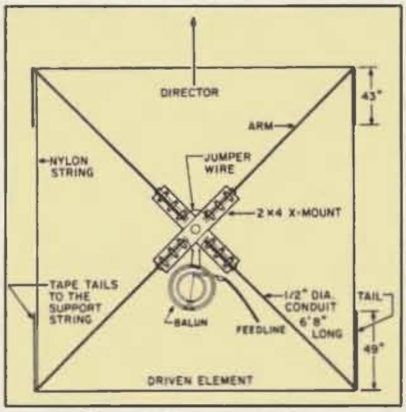

Figure 1. X-beam overview.

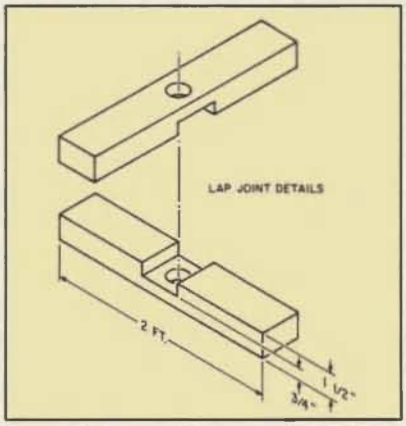

Figure 2. Lap joint for assembly of the X-mount.

but I've never been that fortunate. Fear not—this antenna can be readily constructed using common materials such as wood, steel conduit, and PVC pipe.

I bought the conduit, the PVC pipe, the pipe clamps, and the two-by-fours for less than ten dollars. The miscellaneous hardware alone, if purchased, should cost only a few dollars.

Antenna Components and Construction

The electrical components of the antenna consist of four tubular arms with a wire tail attached to the end of each one. Two arm assemblies are connected and tuned to form a director element; the other two are tuned and form the driven element.

The mechanical components of the antenna consist of a small X-hub in the center, along with a cord which strings the arms together. The hub supports the radially configured arms, and the cord supports the tails in the same plane as the arms. The electrical components of the coaxial transformer consist of six 50" pieces of 50 ohm coax.

The Hub

I built my hub with two 2' pressure-treated two-by-fours. Join them at the center with a lap joint (see Figure 2). Cut the lap joint with

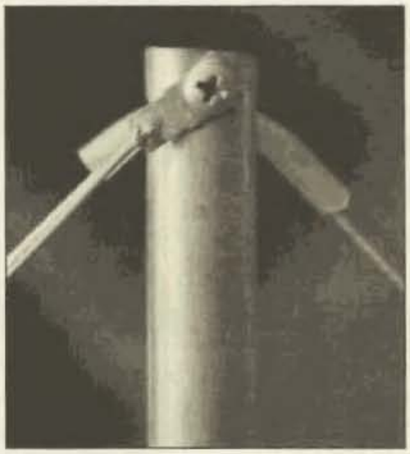

Photo B. Tail attachment and support method. Note the use of silicon tubing to protect the tail support cord.

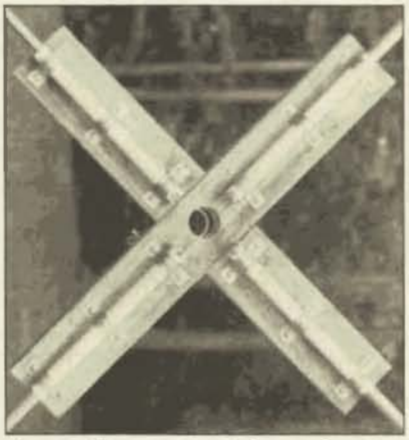

Photo C. The completed hub assembly of the antenna, prior to installation.

a saw and chisel or with a dado blade. Join the pieces with screws and epoxy or waterproof resin glue. Cut a hole in the center to accommodate the mast.

As an alternative, especially for prototyping, substitute a piece of plywood for the two-by-fours. Use exterior plywood and varnish it. I chose the two-by-fours so that the hub wouldn't ice up as much.

The Arms

My local hardware stores don't carry 6061-T6 aluminum, but they stock a nice selection of steel conduit. For this antenna, the steel conduit is an acceptable substitute. The ½" size is close enough to the 200-to-1 length-to-diameter ratio specified in the design article.

Buy four 10' lengths of ½" EMT conduit. Cut each piece to 6'11" with a hacksaw. Clamp the conduit to your workbench and drill a vertical hole at each end to accept the electrical connections.

The Tails

My installed antenna uses #19 AWG stranded hookup wire for the tails, but I've also used #12 AWG home-wire. The wire size will affect the length of the tails required to achieve resonance. The smaller the wire, the longer the tail. I prefer the larger, more solid wire as it remains straight even if the support cord shifts or stretches.

For a center frequency of 28.3 MHz, cut two director element tails, each 43" long, and two driven element tails, each 49" long. These lengths provide about 2" extra for tuning if #19 AWG wire is used. Solder a wire terminal to one end of each wire.

The most important consideration is to always maintain a difference of 6" between the driven and the director tail element lengths. Using two different colored wires for the driven and director element tails can help to reduce confusion later.

The Tail Supports

The tails must be supported in the same plane as the arms. I used 3/32" nylon cord threaded through holes drilled in the end of each arm. I used silicon tubing to provide strain relief for the cord.

Put the tail support holes 90 degrees and ½" in from the hole drilled for the electrical connection. This inset prevents the nut and bolt from touching and rubbing through the tubing.

Drill the tail support holes at one end of each arm using a ¼" drill bit. De-burr the holes with a piece of emery cloth. Cut four 2" pieces of silicone tubing and set them aside. Do not install the tubing until after the arms are insulated and installed. Silicone tubing is sold at aquarium shops as airline tubing, and at hobby shops as fuel tubing. Dacron™ or Kevlar cords are preferable, as they weather well and won't stretch as much as nylon.

Insulating the Arms

The arms should be insulated from the hub for consistent performance. I used ½" type SDR PVC pipe (not schedule 40). It provides

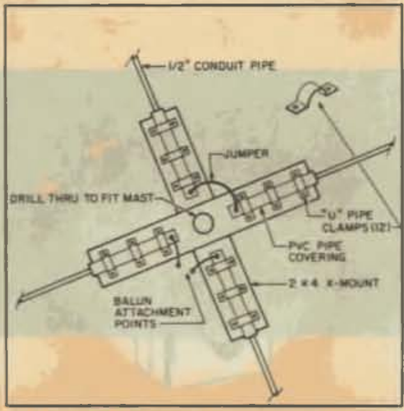

Figure 3. X-mount construction details.

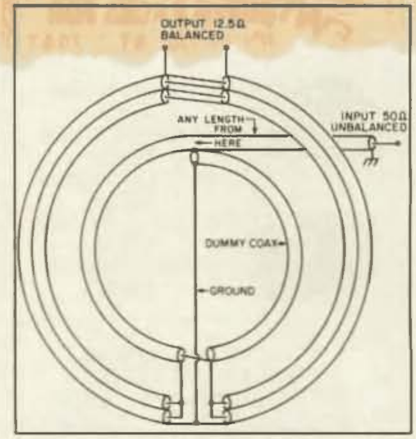

Figure 4. Collins balun.

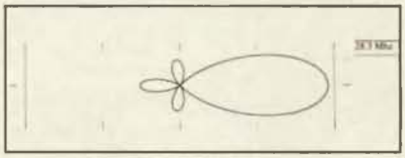

Figure 5. X-beam pattern.

a good, albeit tight, fit around ½" EMT conduit.

Cut four 11" lengths. The fit is very tight, so use warm soapy water as a lubricant. Start a length of PVC over the inside end of the arm. Install it fully by repeatedly driving it against a concrete floor. Repeat this procedure for the remaining arms. Substantial force can be used without damaging the PVC. Sanding the conduit may help, but be careful not to sand through the zinc coating.

Open up the electrical connection holes you drilled by cutting away some of the PVC. I used a ⅜" spade wood bit in my drill to shave it away. You can use a knife, but the PVC is difficult to cut.

Building the Coaxial Balun

This Collins coaxial balun consists of two stages. The first stage matches 50 ohms unbalanced to 50 ohms balanced; the second matches 50 ohms balanced to 12.5 ohms balanced. Use a compact low-loss coaxial cable such as RG-8X—this balun is bulky.

Build each stage separately, then solder them together in series. To prevent confusion

later, mark the ends of the lengths of coax before you begin winding them. Keep the interconnections short. Use the coaxial braid at the 12.5 ohm output to connect directly to the antenna feedpoints.

Figure 4 shows the interconnections and layout as if the balun wasn't coiled. In practice, the lengths are wound into a coil with a diameter of six or seven inches. This diameter isn't extremely critical; it depends on the coaxial cable you use. The ground wire should be short, but its length isn't critical, either. The dummy length of coax in the input stage can be replaced with a wire, provided it is the same length (50"), and is wound in the same manner.

Use electrical tape to hold the windings together—sparingly during construction, and with a vengeance prior to installation. Waterproof the balun by using a polyurethane spray or a silicone rubber compound.

Putting it Together

Prepare the hub. (Refer to Figure 1 and Photos B and C for detailed views.) Start by marking a centerline on each two-by-four. Next, place the pipe clamps. I used three pipe clamps per arm: one at each end, and one in the middle. Be sure to use the proper type of clamps—½" electrical clamps for clamping conduit directly, and ½" plumbing clamps for clamping the insulated arms. Locate the inner edge of each innermost clamp 1¾" from the center to provide clearance for the mast. Drill pilot holes for the clamp screws. Install the clamps loosely.

Install the arms by slipping each arm, in turn, under the clamps, then snugging the clamps. Allow the inner end of each arm to extend ½" beyond the edge of the inside clamp. This provides access to the end of the arm for electrical connections. Clamping the hub to a workbench or your deck reduces the number of hands required for this procedure. Rotate each arm to properly align the electrical and tail support holes, then tighten the clamps securely.

Next, attach each tail loosely to the arm. If possible, use stainless hardware. Be sure to install the director element and driven element tails properly. This step is best performed before you install the tail support tubing.

To support the tails, install a 2" piece of silicone tubing through the hole at the end of each arm. Thread the tail support cord through each arm in turn. Pull the cord tightly, as it will sag when the tails are attached. Line the tails up along the cord and secure them at several points with electrical tape. Tighten the tail-to-arm connections securely.

To wrap it up, connect the director element arms. I used a short piece of #12 AWG copper wire. Coax braid will also work well.

Feeding the Antenna

The feedpoint impedance of this antenna is 10 ohms at resonance. With proper matching to 50 ohm coaxial lines, this antenna provides a 2:1 VSWR bandwidth of about 600 kHz on 10 meters.

For my prototype antenna I used a coaxial "choke" balun consisting of 10 turns of coaxial cable wound into a 6" diameter loop. I matched the transceiver to the line using a transmatch.

For my installed antenna I used the two-stage Collins balun described in this article. This balun provides a 12.5 ohm balanced to 50 ohm unbalanced transformation. A 2:1 VSWR bandwidth of 600 kHz is exhibited without the use of a transmatch.

I strongly suggest the use of a balun, and I heartily recommend the Collins class of baluns, but the coil-of-coax type will work in a pinch.

Tune-Up

Install the beam on your test tower. I used an 8' wooden ladder for my test tower. It's high enough off the ground, yet access to the tails is convenient.

Tune-up is accomplished by trimming the tails. Be sure to keep the director element tails and the driven element tails the same lengths, respectively. Also, be sure to maintain a difference in length of 6" between the director element tails and the driven element tails.

Use a dip meter, noise bridge, or SWR meter to test for resonance. I borrowed a dip meter for the tune-up procedure. If you use a dip meter, be sure you are familiar with its limitations. During my tests, I found that the antenna was resonant at a frequency 5% higher than that indicated by the dip meter.

Proceed by trimming the tails ½" at a time, testing for resonance until the correct resonance is achieved. Note that the antenna is fairly sensitive to nearby objects, such as your body.

Perform the final tune-up with the antenna installed. I ended up with director element tail lengths of 41", and driven element tail lengths of 47", for a resonance at 28.3 MHz.

Prototyping

This is a very easy antenna to prototype. The difference between my prototype and the installed antenna was about $3, plus an hour of labor.

I prototyped mine by directly clamping the conduit to a scrap piece of wood. I attached the wire tails with ground wire clips, supported the tails by taping them to a cord drawn around the perimeter, and made the connections at the hub by clamping the wires under the pipe clamps. I completed my "installation" by clamping it to an 8' wooden ladder in my living room.

Installation

I installed the beam at the base of the top section of my 36' push-up mast, inverting the beam and attaching it to the underside of the guy ring. I had to do this to prevent mechanical interference between the hub and the clamp for the top mast section. I did not have to worry about interfering with guy wires, as my mast is not guyed. The mast's sheltered location, light antenna load, and mechanical attachment to the house, precluded the need for guy wires.

To prevent rotation about the mast, I fashioned two L-shaped pieces of plumber's metal strapping and screwed them to the guy ring. I secured the assembly to the mast with a hose clamp. This is adequate for me, as I don't have a rotor, and I am using the antenna for fixed direction schedule work. As an alternative, especially if you are using a rotator, use a heavy-duty L-bracket with pipe clamps that fit your mast.

Complete the installation by securing the balun to the mast. I wound electrical tape through each stage of the balun, and around the feedline below the balun.

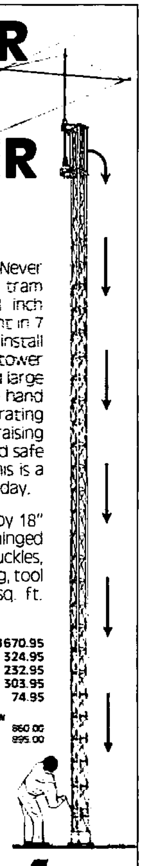
I'm confident that you'll find this to be a compact, high performance beam which is easy to build and won't lighten your pocket book. Enjoy it! Be sure to remember that "59" means "armchair copy" and "20 over 9" means "You woke up the kids." You'll be hearing this new jargon often!

Contact Michael Harris KM4UL at 5917 Crabapple Rd., Durham NC 27712.

Parts List

4	10' lengths of ½" EMT conduit
1	10' length of ½" SDR PVC pipe
12	½" plumbing pipe clamps
1	8" length of silicon tubing
4	4' lengths of wire scraps
2	24" lengths of pressure-treated two-by-four
6	50" lengths of coax (RG-8X preferable)
	Misc. Hardware as required

Enjoy NEVER CLIMBING YOUR TOWER AGAIN



Are you too scared or too old to climb? Never climb again with this tower and elevator tram system. Voyager towers are 13 and 18 inch triangular structures stackable to any height in 7 1/2', 8 3/4' or 10' section lengths. Easy to install hinge base, walk up erection. Next plumb tower with leveling bolts in base. Mount rotor and large heavy beams on Hazer tram and with one hand winch to top of tower for normal operating position. Safety lock system operates while raising or lowering. At last a cheap, convenient and safe way to install and maintain your beam. This is a deluxe tower system that you can enjoy today.

SPECIAL TOWER PACKAGE: 50 ft. high by 18" face tower kit, concrete footing section, hinged base, HAZER kit, Phillystran guy wires, turnbuckles, earth screw anchors, 10' mast, thrust bearing, tool kit, ground rod and clamp, rated at 15 sq. ft. antenna load @ 100 MPH, **$1974.95.**

57' by 13" wide tower, same pkg as above	**$1670.95**
HAZER 2 for Rohn 25-hvy duty alum 12 sq ft wind ld	**324.95**
HAZER 3 for Rohn 25-std alum 8 sq ft wind load	**232.95**
HAZER 4 for Rohn 25-hvy galv. stl 16 sq ft wind ld	**303.95**
[illegible] thrust bearing [illegible]	**74.95**

HAMS WITH CLASS

Carole Perry WB2MGP
P.O. Box 131646
Staten Island NY 10313-0006

A Family Affair

"How can I get my own children interested in ham radio?" is the second most-frequently asked question. You've probably guessed that the most popular query is still, "How can I get my wife to become a ham?" Let's address the offspring problem in this column now. We'll save the spousal issue for another time.

Helping parents and children work together on any project is a worthwhile endeavor. Throughout the last 10 years of teaching ham radio, I've always encouraged the youngsters to study at home with their parents. The parents love the idea of learning new material along with their children. Here at last is a subject where parents and children can be on equal footing with each other. It's a chance for real active participation in their children's academic lives. Most parents are quick to see the benefits of encouraging their youngsters to get involved with a technical and stimulating hobby.

In order to motivate the 6th, 7th, and 8th graders in my "Introduction to Amateur Radio" classes to include their parents in their own quest for a license, I tell them to "study at home with the person who has the money. If your mom or dad gets a license too, they'll probably buy ham radio equipment for your family to use." The kids love the idea that they're putting something over on their folks. Years later, when I get the siblings of these children in my class, they come back with their parents during Open School Week to tell me how much ham radio has contributed to the quality of their family-time together. The burden then falls to the young sibling in my class to carry on the family tradition. I've gotten enough positive feedback about the fun that ham families have, that I make it a point to encourage it whenever possible.

Getting back to the original question, many hams have written to me over the years, perplexed at why their own youngsters don't seem to share their love of amateur radio. Of course, those of us who are parents know all too well that sometimes the more we encourage, cajole, or bribe our kids to do something that we'd like them to do, the more they pull away from it. Some degree of rebellion is a natural part of growing up. Children have a need to assert themselves and establish their own identity. Much to our chagrin, at times this means rejecting whatever mom and dad may consider a real good idea.

Through the trials and tribulations of child rearing, there are many proud and happy moments that help counter the negatives. Keeping all this in mind, the best advice to a ham parent is not to use overkill when attempting to convince your children to become hams. Just be yourself and let the youngsters see you enjoying your time on the radio. Enjoyment and enthusiasm tend to be contagious. Never underestimate the vibes that children pick up as they watch you having fun and being challenged by your radio activities. There's a time when the smile of satisfaction or the expression of excitement on your face says a lot more than any words you can say.

Among the countless benefits I've experienced in my role as a ham radio teacher has been the privilege of having children of hams in my class. Don't think for one minute that these parents had an easy time of it. Not one of the nine youngsters in this category were licensed when they were assigned to my class. That should tell you something right there. Another statistic is that they all became licensed at the end of the program. There are simply times when an eleven-year-old thinks it's OK to do something because their peers are all doing it, not because a parent would be overjoyed to have them do it.

The following are stories of some boys and girls whose parents were ready to move heaven and earth to get them involved in ham radio. They wound up in my ham radio program which provided them with the opportunity to be in a class with other children who were eager to get a ham ticket. Working and having fun with other teens was just the extra motivation these kids needed. Before we knew it, they were going home and proudly reporting their new-found radio experiences to their ham parents. At first the dads were surprised that the children acted as if it were their first exposure to ham radio. Then they realized that this was just the kids' way of asserting their separateness. Smart parents should listen attentively to their children's reactions and anecdotes. Encourage them to tell you about their experiences with the other students. We all need to feel we have something unique to offer our families.

So, getting your offspring enrolled in a local ham radio class in a school or club is a great idea. Don't ever assume there's a genetic predisposition to becoming a ham. Set the stage with your own enthusiasm and then encourage them to go with a friend to a structured class. You've already planted the seeds; now sit back and let nature take its course—with the help of an objective, good ham radio instructor.

Gerald D. Fox, D.D.S., WA2VKS

"One hundred baby chicks!" That's what the man said. I was 12 years old; it was late at night in 1960, and I was lying in bed listening to WWVA on the radio, all the way from West Virginia. The commercial on the radio reminded me of how different life in other parts of the country must be from my life in New York. What would a city boy do with a hundred baby chicks?

Photo A. Jerry Fox WA2VKS visits his daughter, Loren KA2JNV, at the school ham shack.

That summer, I went to my friend Larry's house to sleep over. Larry reached under his bed and pulled out a shortwave radio. Voices from other lands speaking many languages filled my ears. Larry tuned around the dial and suddenly the voices sounded different. I wasn't hearing polished, professional broadcasting. This was conversation. These people were talking to each other. Then I heard a British accent; people were talking across the ocean! I was hooked.

The next summer I went to a camp, and I was delighted to discover a new activity. The camp had a ham shack, complete with a Gonset "gooney box." Myles, the counselor, taught me code and theory, and that summer I passed my Novice test.

Ham radio has stayed in my blood. I worked my way up the ladder, getting each class of license, including amateur Extra. It was time to pass it on!

I now have a 12-year-old daughter attending Intermediate School 72 in Staten Island, New York. You can imagine how thrilled I was when I found out that they had a ham radio program. I met Carole Perry, the instructor, whom I'd spoken to many times on 2 meters. I knew my daughter would have to take this course!

Carole made it fun. Loren called me at work each day and told me what she'd learned. Hearing of her progress almost made me cry. The class has both an HF and VHF setup, and I had the pleasure of talking to Loren in class via the local repeater.

Loren did get her Novice license after studying in Carole's class. She is still a little mike shy, but she told me today she'd like to get some practice on the air. You know, I loved it!

Shaun Gartenberg KB2JNW

I am a 13-year-old amateur radio operator. Both of my parents are hams as well. My father, Martin Gartenberg WA2YYX, has been a ham radio operator for about 30 years. He was introduced to the hobby at an early age by a friend. He holds a Technician class license, and is active in several Staten Island radio clubs. He was also president of the Chaverim Radio Club in Perth Amboy, New Jersey. He's been good friends with Mrs. Perry for over eight years. He was always telling me how much fun it would be to get into her ham radio program when I went to Intermediate School 72. He was right!

My mother, Rachelle Gartenberg KB2DBF, has been a ham for two years. She was introduced to the hobby by my father who helped her study for the Novice license. She is a schoolteacher who plans to upgrade in the near future.

Photo C. The Tropps: Charles N2CDV, Laura KA2WUH (in the middle), and Deborah KB2KXU

Photo D. Lori Perry KA2TCC and Carole Perry WB2MGP.

I became a ham in January 1990, and I love it. It's an interesting and exciting hobby. I was in Mrs. Perry's radio class when I was in the 7th grade. It was here I found out how much fun my friends and I could have in ham radio. I'm a Novice now, but I'm studying for my upgrade. This year as an 8th grader, I'm in Mrs. Perry's homeroom class. Many of the other students in this class are hams, too. It's great in the morning when we're in homeroom. We're right near the ham shack. Not only is it fun to talk on the air in the morning from school, but in my case, it's great because I can talk to my dad. He's so proud of me.

I have a 9-year-old sister named Meredith. She's not a ham yet, but my parents and I are sure she will be in the future.

Charles Tropp KA2AHA

Although interested in ham radio since grade school, I didn't get my first license with callsign KA2AHA until 1978, after completing an adult education course at Susan Wagner High School. I started operating in the spring of 1979, and I got my General license as N2CDV in 1980. Laura KA2WUH received her Novice license as a student of Mrs. Carole Perry in 1985 at I.S. 72 on Staten Island. Deborah KB2KXU got her Novice license in 1990 also at I.S. 72. Our station consists of an ICOM 751 and a dipole at 40 feet. We also have 10 meter FM capability, and we can operate on all HF bands. We enjoy being a ham family.

Lori Perry KA2TCC

My name is Lori Perry, callsign KA2TCC, and I'm 20 years old. Nine years ago I attended Intermediate School 72 where my mother taught a ham radio course. At first I was mortified to learn that several of my friends were going to be in my mother's class. For years, my mother tried to get me involved with her hobby. Actually, it wasn't until my friends started talking about it that I began to consider it seriously.

Today I'm a communications major at Hofstra University. Ham radio has been influential for me from the moment I went for my entrance interview, to my present choice of media courses. The woman who interviewed me spotted an HT antenna sticking out of my bag and asked about it. In retrospect, it was obvious that she was impressed.

I haven't been very active in the last few years, but I am very pleased and proud to be a ham. There have been many family activities, like vacations and trips, where it was really nice to have a ham for a mom. ■

SPECIAL EVENT STATIONS

VERMONT Throughout the coming year, Special Event Stations from Vermont will be on the air to help Vermont celebrate its 200th birthday. A special 200th Anniversary Certificate is available. SE Stations will be operating 25 kHz up from the bottom of the Novice and General bands. RTTY/AMTOR/etc. will be in the digital sub-bands. For certificate, send $1 and a SASE to *Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654.* Foreign stations, send only SAE and IRC's to cover postage.

APR 15

FORT PIERCE, FL The Fort Pierce ARC will operate KJ4YF from 1400Z–2100Z to commemorate the 4th Annual Trail Ride of the Florida Cracker Trail Assn. Operation will be on the 40, 20, 15, and 10 meter phone bands, and the Novice portion of 10 meters. For certificate, send QSL and large SASE to *FPARC, PO Box 0004, Fort Pierce FL 34954.*

APR 21

DELAWARE Never ones to learn from past mistakes, the members of the Warminster ARC will conduct their third annual DXPedition to the rare state of Delaware, operating WA3DFU/3. Frequencies: 7.275, 14.275, 21.375 and 28.375 MHz. CW contacts will be made on request. QSL with SASE to *Warminster A.R.C., Box 113, Warminster PA 18974.*

ST. LOUIS, MO The Suburban ARC will operate WØDCW, from 1800–2400 UTC, to celebrate the 44th Anniversary of the Club. Operation will be on the lower portion of the General Bands and 28.425 MHz (Novice 10 meter). Please send SASE for a QSL card to *Henry G. Schaper, Sr. KAØAWS, 241 Tapestry Dr., St. Louis MO 63129.*

APR 20-26

MADISON, WI The West High School ARC will operate Station KB9NG from 1300Z–2200Z, to commemorate West High School's Fine Arts Week. Frequencies: Lower 30 kHz of the General 20 meter and 15 meter phone bands and 10 meter Novice phone band. QSL, SASE to *WHARC, 30 Ash St., Madison WI 53705.*

APR 25-28

PADUCAH, KY The Paducah ARA will operate W4NJA to celebrate the annual American Quilters Society Convention. Frequencies—CW: 7.125, 14.050, and 21.150 MHz; phone: 3.875, 7.250, 14.250, 21.375, and 28.450 MHz; packet: 145.010. For QSL, send QSL and large SASE to *Paul Smith N4FFO, 229 Nickell Hts. Rd., Paducah KY 42003.*

APR 27

THOMASVILLE, GA The Thomasville, Georgia ARC will operate W4UCJ from 1830Z Apr. 26th until 0200Z Apr. 27th, and 1530Z–2300Z Apr. 27th, to celebrate the 70th annual Rose Festival. Frequencies: Lower CW portion of the General bands and Novice SSB portion of 10 meters. For a certificate, please send QSL and SASE to *Thomasville ARC, PO Box 251, Thomasville GA 31799-0251.*

POUGHKEEPSIE, NY The Poughkeepsie RAC will operate Station K2KN from the Young/Morse Nat'l Historic Landmark on the Hudson River from 1400 UTC–2000 UTC, to celebrate the 200th birthday of Samuel F.B. Morse. Frequencies—CB: 3.710, 7.110, 14.050, 21.110, 28.110 MHz ±10 kHz. SSB: 3.90, 7.235, 14.235, 21.335, 28.40 MHz ±10 kHz. DX QSL cards responded to via the ARRL DX Bureau. USA QSL cards answered when receiving SASE, and if a special certificate is desired, a 9"x12" SASE. Send to *Ted Zulkowski K2JMY, 4 Bishop Dr., Poughkeepsie NY 12603.*

INTERNATIONAL MARCONI DAY This year's event will be celebrated from 0000Z–2400Z. There will be about 15 stations representing Marconi communication sites around the world. North American sites are VE1IMD, VO1IMD and K1VV/IMD. Most site stations will use the suffix "IMD" or "/IMD." A certificate (modeled after an actual Marconi stock certificate) is offered to those who work the most Marconi sites (the number will be announced on the air). More award details will be given by site stations. All modes may be used this year; CW, RTTY, SSB and packet. The event is coordinated by the *Cornish RAC, PO Box 100, Truro TR1 1RX, Cornwall, England.*

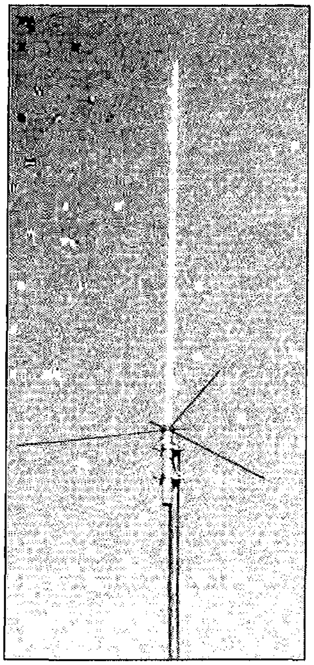
APR 27-28

U.S.S. OLYMPIA The Olympia ARC will operate Station WA3BAT from aboard the U.S.S. Olympia, from 1300 UTC Apr. 27th–2000 UTC Apr. 28th, to commemorate the 92nd Anniversary of Admiral Dewey's triumph over the Spanish Fleet at the Battle of Manila Bay during the Spanish-American War. Frequencies—CW: 7.133 MHz; RTTY: 40, 20, 15 meter bands; 2 meter FM: 145.270; phone: 3.895, 7.245, 14.245, 21.365 and 28.365 MHz (±5 kHz QRM). For certificate, send QSL and 9" X 12" SASE with three units of postage/IRC's to *Olympia RAC WA3BAT, PO Box 928, Philadelphia PA 19105.*

NEW PRODUCTS

Compiled by Hope Currier

PRODUCT OF THE MONTH

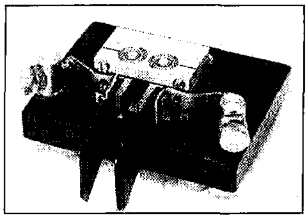


NCG Model CX-908

The Model CX-908 from NCG/COMET Antenna is the world's first triband base antenna for 144, 430 and 900 MHz. This one-piece, Fiberglas™ antenna will withstand wind velocities of 134 MPH, and is completely water/pollution-proof. It is extremely wideband, so it doesn't require frequency adjustment. Its lightning protection guards your transceivers. Using the CX-908 with a COMET triplexer (CFX-431, CFX-4310) will allow three-band TX/RX communications at the same time.

For prices and more information, contact *NCG Co., 1275 North Grove St., Anaheim CA 92806; (714) 630-4541; FAX (714) 630-7024.* Or Circle Reader Service No. 201.

Palomar Engineers



Many top CW operators consider the Kent key to be the world's best. The design and machining of the precision brass mechanism is by R. A. Kent Engineers in England; the key is assembled at Palomar Engineers in the United States. It features rotary ball bearings, fully-enclosed springs, and individual knurled thumbscrews to adjust dot and dash contact spacing and spring tension. The key has a smooth, effortless action because it has rounded paddles that are easy on the fingers. The small footprint (3" x 4") steel base weighs over two pounds.

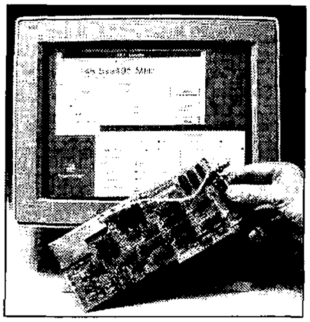
The price is $100, plus $4 shipping for the United States and Canada. Contact *Palomar Engineers, P.O. Box 455, Escondido CA 92033; (619) 747-3343, FAX (619) 747-3346.* Or circle Reader Service No. 203.

JDR Microdevices

JDR Microdevices has just released a new "Power Up" catalog, filled with products to help computer enthusiasts maximize the speed and efficiency of their equipment. The new products include JDR's own FrontPanel, a bus extender and instruction execution detector in one, perfect for hardware and software debugging; and JDR's Breadboard-on-a-Card Series, with decode, for faster, easier prototyping. Other new items include an accelerator card for A2000 with a high speed 28 MHz 68030 CPU, a modular circuit technology 486 motherboard, Amiga products, and an expanded software line with numerous software products for Windows.

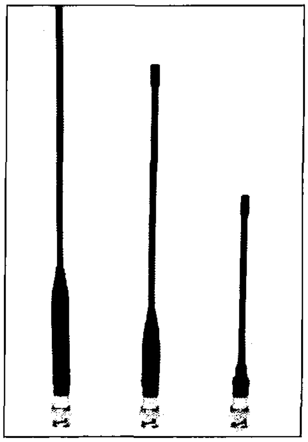
For a copy of the catalog, contact *JDR Microdevices, 2233 Branham Lane, San Jose CA 95124; (408) 559-1200, FAX (408) 559-0250.* Or circle Reader Service No. 204.

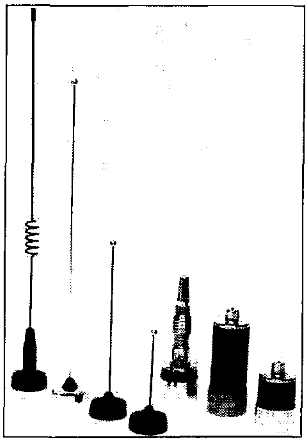
Optoelectronics



Optoelectronics has announced a radically new type of universal frequency counter-timer: a 9-inch drop-in card for personal and laptop computers. It uses Windows 3.0 as a control panel and display window, and it directly tunes radio receivers such as the ICOM R7000, resulting in a uniquely-configured self-tuning radio. The Model PC-10 is a 10 Hz–2.4 GHz radio instrument that competes with more expensive big name products. It measures, captures and analyzes discrete and average frequency readings, pulse width, time interval, period, and the ratio between two frequencies. It provides a useful "reciprocal counting" feature for 8-digit resolution of low frequency readings.

The Model PC-10 is priced at $335 in unit quantities. The Model AP10H option ($295) provides custom input amplifiers, signal conditioning and frequency prescalers. Contact *Optoelectronics Inc., 5821 NE 14th Avenue, Fort Lauderdale FL 33334; (800) 327-5912, (305) 771-2050, FAX (305) 771-2052.* Or circle Reader Service No. 205.





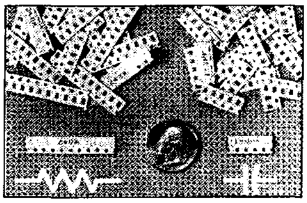
Valor Enterprises

Valor Enterprises has introduced a new line of rubber ducks (above left) available for 140, 220 and 440 MHz. These new portable antennas feature a BNC connector and a long-lasting vinyl dip coating for years of reliable service.

Valor, a longtime leader in the manufacturing of cellular and CB antennas, is also offering the new Omni-Gain line of land mobile antennas (above right) in all frequency ranges, including 900 MHz. A wide variety of mounting hardware is available.

For prices and more information, contact *Valor Enterprises, Inc., 185 West Hamilton Street, West Milton OH 45383; (513) 698-4194, (800) 543-2197, FAX (513) 698-7273.* Or circle Reader Service No. 202.

Communications Specialists



Communications Specialists, Inc. is now offering surface mount resistors and capacitors in small quantities and in individual values. The unit of sale is "per strip," and there is a $10 minimum requirement per order. Resistors come in strips of 10 for $2.50 per strip; capacitors come in strips of five for $1.25 per strip. Each strip is clearly marked with the value.

Contact *Communications Specialists, Inc., 426 West Taft Avenue, Orange CA 92665-4296; (800) 854-0547, (714) 998-3021, FAX (714) 974-3420.* Or circle Reader Service No. 206.

Number 20 on your Feedback card

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

User Rights, Revisited

Since I began writing this column back in 1972, the single question that I have been most often asked to address is that of the rights of repeater users in determining the overall operating standards of a given system. I'm not just referring to the technical aspects of system operation, I'm thinking in terms of every aspect: technical, social and legal.

Where I live, repeaters come in three categories: open machines, closed machines and private machines. Actually, if you add the so-called "super private" and the "pirate/uncoordinated" systems, there are really five very different operational categories. Thankfully, the rest of the nation is not as title-conscious as Southern California. Almost everywhere else, all you find are open and closed coordinated boxes and a smattering of the "uncoordinated" pirates.

In my travels nationwide, I have noticed one amazing thing: Whether a repeater is open or closed, it usually falls under one distinct form of internal operation. Either it is a club repeater whose operation is governed by a repeater trustee elected by the membership, or it is an individually owned and operated system, run by what has become known as a "benevolent dictator." In either case, the outcome is the same. An individual or a small group determines what all others who pass their audio through a repeater can or cannot say. There is a monarchy, so to speak, where there are essentially "gods" in the form of repeater owners, and "peasants" in the guise of a repeater's usership. This is the basic and tenuous relationship that really has been around since the days of the old AM repeaters in the late '40s, and out of it has grown the vast repeater network that spans the length and breadth of the United States, as well as its neighbors to the north and south.

At this point, it is probably fair to say that if the system works, why change it? I think you can answer this question by asking, "Why change apartheid?" If you think about it, what is going on in South Africa and on the VHF/UHF repeater subbands is really the same in essence—a small minority lording over a vast majority. Be it for racial reasons or ego fulfillment, playing God over others is just not tolerated in this society or age.

The truth is that the system has not really worked. Oh, I'll admit that it is staggering to have almost 10,000 repeaters on 2 meters in the United States. According to listings in the *ARRL Repeater Directory*, that is. The number approaches 15,000 when you take all other bands into account. And that is not even considering the thousands of remote bases that sit atop mountains and tall buildings, giving a single individual with a handheld total access to all modes on all bands. So, on the surface, there is a look of success.

But when you listen closely, you find that there are a lot of very unhappy people out there. These are people who, by virtue of the fact that they have invested money in a handheld, a mobile, and a base radio installation, feel that it is their God-given right to also demand a say in the way every aspect of every repeater they use is to be run. In the '70s, these people were openly called "fanatics" by their peers. In the '80s, their call began to get some valid attention as their numbers began to grow. Now, with the end of the first year of the 1990s, the concept of user rights has surfaced again, and this time it has the backing and support of a wide segment of the population of Southern California.

In fact, like it or not—and that depends on whether you are a repeater owner or a repeater user—the demand for so-called "user rights" is now the hottest topic in this part of the country, and as word of the coordination board action of October 6, 1990, begins to reverberate across the nation, it is sealing the fate of repeater "gods" everywhere. It is saying to repeater owners—be they clubs or individuals—that the day of total owner control is at an end. It has now ended in my part of the world, and you can be pretty certain that it will eventually end in yours. It ended because a repeater coordination council has said to the world that the wants, wishes and desires of repeater users take precedence over anything that a system owner may want or demand. TASMA has said that users do have rights!

The TASMA Meeting

TASMA, Southern California's Two Meter Area Spectrum Management Association, is the 2 meter by-band coordinator for all activity across the state, and south from the Tehachapi mountain range down to the Mexican border. The other two are SCRRBA, the Southern California Repeater Remote Base Association, taking care of 6 meters and all UHF/Microwave coordination; and the 220-SMA which, as its name implies, coordinates 220 MHz. But, unlike repeater councils, both TASMA and 220-SMA are chartered as overall spectrum management groups. In other words, repeater coordination is only supposed to be a tiny part of all-around band management. All three groups can trace their lineage to the original California Amateur Relay Council, the nation's first coordination body in the late '50s.

As such, TASMA is hardly a Johnny-come-lately to the arena of settling disputes between repeaters, but until now, even it has shied away from tackling a repeater-user versus repeater-owner fray. But when it broke away from the now-defunct Southern California Repeater Association in 1979, it also widened its sphere of influence to include every signal that would ever be put onto 2 meters in the region, and its bylaws gave the promise of equal representation before the membership to any individual or group that requested it. So, TASMA agreed to listen to the complaints of a group of users who claimed that the owner of the repeater they used was literally pulling the rug out from under them. They claimed that the owner, Dave Witt KE6HN, was using the repeater to punish them because he did not like the way that they operated. He did this by locking out the repeat function and playing Gordon West Radio School CW training tapes—music and all—whenever he or his control operators did not like what was being said.

The user group bringing the matter to TASMA was from the 147.435 machine, a high-tempered system that has gone through more than a half-dozen owners since its inception over two decades ago, starting out as WA6TDD in the late 1960s. The .435 system, whose callsign when this story began was KE6HN/R, sees and talks to much of the southern portion of the state, with coverage into northern Baja California, Mexico. Even on its odd-split frequency pair of 147.435 in/146.40 MHz out, it was one of the nation's most populous repeaters, with a user base in the late '70s nearing 700. But numbers brought problems. Unlicensed operators, jammers, and a smattering of foulmouths worked their way into the daily regimen of .435 operation. The situation kept getting worse and worse, and the system owner wanted to clean it up, but the users of .435 wanted a free and open forum for discussion of any and all subject matter. They wanted no prohibitions on language, and said that each would take legal responsibility for what he or she said on the air. This conflicted with recent interpretations of the Part 97 rules which place shared responsibility for content of repeated communications on the originating station and the licensee of the relay operation. This notwithstanding, the usership demand was for minimal control by the system owner, Dave Witt KE6HN.

The Winds of Change

In mid-1990, KE6HN petitioned TASMA to permit him to close and make private the long-established open .435 machine. Reportedly, this was to be a part of the way in which he would change the atmosphere on .435 and clean out the "rat's nest." TASMA told Witt that the frequency pair was reserved for an open operation system, and that he must continue operation in that category. (In Southern California, once a system's operational format has been established, no changes can be made without the approval of the coordination council.)

Witt was also told by TASMA that the code practice tapes that he was running to censor user comments and counter what he felt to be abusive user behavior must be stopped. While the precedent of using code practice tapes to control user abuse was established in the 1970s on the old K6MYK repeater, not until now has this system owner practice been challenged by users before a coordination body.

TASMA Acts

Based on audiotapes provided, and a petition from the users written by Professor Roy Tucker N6TK and circulated by Jensen Woods WB6ZFU, TASMA's membership voted to issue a "Show Cause" order to KE6HN, giving him until the next TASMA meeting (approximately 30 days) to show the coordination organization why he should not lose his right to operate the repeater bearing his callsign. He was also admonished in absentia for changing the repeater callsign to one of another ham, and TASMA has indicated that it will not recognize such a change because its coordination guidelines call for pre-approval of any such operational modification.

In issuing its decision against Witt, the TASMA Board of Directors made it clear that the repeater's user base, and the system owner adhering to the long established use of the channel for open operation, were their prime interests. They also indicated that repeater users have a right to expect that repeaters will always be run as the channel pair sanction stipulates—a stand that many coordinators have held privately, but never before shown so forcefully in public.

TASMA then stripped Witt of his sanction to operate the .435 repeater and recoordinated the frequency pair to Jensen Woods WB6ZFU. Witt was given a chance to file an appeal, which he did. But before the appeal could be heard, Witt surprised everyone by selling off the repeater hardware to Roy Tucker N6TK and Woods, thus codifying the TASMA decision as a "de facto" coordination regulation for the region. As we go to press, Woods is doing everything humanly possible to rid .435 of its jammers, foulmouths, carrier-throwers, unlicensed operators—and its bad reputation in the area. At this writing, what he has undertaken seems to be an almost superhuman task, and we wish him well. Will WB6ZFU succeed where many others have failed? Only time will tell.

A Public Utility?

There is a caveat to this change. In effect, TASMA has unintentionally codified what many hams have felt for the better part of two decades. That is, repeaters are now not as much ham radio stations as "amateur radio public utilities." They, along with the newer packet digipeaters, are the de facto "telephone and telegraph relay stations" of the world of amateur radio. Hams expect repeaters to be there, 24 hours a

QSO Tutor

Study Aid for the Amateur Radio Exams

All you need to join the ranks of Amateur radio operators.* Obtain your Novice license or upgrade to a higher class the easy way on your personal computer with *QSO Tutor*.

Mac® IBM®

Program Features:

- Runs on IBM Personal Computers and compatibles with minimum 256K RAM or Macintoshes with minimum 512 K.
- Programs are available for Novice, Technician, General, Advanced and Extra Amateur class exams as well as Commercial Radio Telephone and Commercial Radar Endorsement. Each program sold separately.
- Work with the entire question pool, selected areas, or additional questions automatically selected by the program from your weakest areas.
- Includes full screen graphics, explanations on appropriate questions and a pop up calculator on the IBM version.
- Logs multiple study sessions and allows resuming at a later time. Returns to review missed questions if desired.
- Creates randomly generated sample tests on-line or written on Epson/IBM or Macintosh graphics printers.

Now Available - Similar Commercial Radiotelephone license Tutor. $39.95. Commercial Radar endorsement $29.95.

"The most advanced program I've tried... Graphics are extraordinary... This program should be your first consideration."
Gordon West WB6NOA, Worldradio Nov. '89

"Do I recommend the QSO Tutor? Heartily, yes! It really motivated me and it's a great way to test my progress. The learning is a natural by-product of the fun I am having."
Jim Bail KA1TGA, 73 Magazine Review Jan '90

"Thanks to your study program I was able to handle the examination confidently and passed with flying colors. If the Extra Class program is as helpful as the Advanced Class was, I look forward to working with it." **WA0NDF**

"Using QSO Tutor made studying for the exam enjoyable and interesting, thanks to your program I passed the technician test with a perfect score." **N3GME**

"I easily passed my Advanced Class test on the first try thanks to your great software!" **WA3WOM**

"Thanks for thinking of us hams. Your program has eliminated the worry of the Theory part of the test for me." **KA3RHW**

day, seven days a week, 52 weeks a year, at the beck and call of anyone with a ham ticket and the money to purchase a transceiver of his own. Therefore, the TASMA decision regarding .435 in Los Angeles will impact on all of the nation's repeaters and repeater owners in ways never dreamed of before.

Like it or not, TASMA's decision concerning .435 means that organized user groups can now place demands on repeater operators, and those owners will be forced to comply with their whims or be run off the air by someone who will comply. On the negative side, it could mean that a budding system owner who can't find a spot for his new machine might "raid" another repeater's user base for support. On a more positive note, since the user group's voice will be heard as well as the repeater owner's voice, the owner will be able to more actively challenge co-channel and adjacent channel systems to abate any interference. The greatest impact of all may be that of making "closed" and "private" repeaters vulnerable to decoordination in favor of high volume user-load open systems.

If you think that none of this will ever take place, you know little about human nature, and even less about the crowded repeater subbands. I'll bet that it actually begins to happen long before this reaches print. In our litigatory society, it will also only be a matter of time before TASMA's decision to favor user groups over repeater owners leads to court challenges to other repeater coordinators who fail to consider user complaints. It will also most assuredly lead to litigation between user groups and system owners, and vice versa. Then again, no decision made by man is perfect, and TASMA, like all other repeater coordination groups, is made up of human beings.

Hindsight is Wonderful

Ten years ago, in this same column, I predicted that it wouldn't be long before user rights became the most important issue to surface in the world of VHF/UHF relay communications. I was off by about half a decade, but not wrong on seeing the problem. Now it is here, and with it the distinct possibility that tens of thousands of potential repeater owners and users will come to the hobby with no-code Technician class tickets, and the right to put up repeaters of their own.

How do the repeater coordinators and repeater owners of today see themselves? The users—hams like you—are demanding a full measure in determining the way a repeater—all repeaters—will be run. The owners and coordinators may have no alternative but to listen and act on your desires, or take their repeaters off the air forever. As Bob Dylan sings, "...the times they are a changin.'"

Special thanks to Rich Yarigian N6PVP for attending the TASMA meetings and researching much of this story. ■

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

No Fooling

I hate April Fool's Day. I really do! Somehow, there is nothing so low as tricking someone into believing some untruth or fantasy. Unfortunately, so many hams become such fools when they purchase this or that RTTY communications program. This month, I'd like to tell you about a program that won't "fool" you or take you to the poorhouse with cost.

After several editions, Skyline Associates' TRTY.EXE program has matured into one that rivals commercial offerings. Originating in the Heath Computer Radio Net, this program, authored by T.L. Vinson and coauthored by all the participants of the net, features a dual port and split screen radioteletype interface that allows full computer control of a RTTY station.

The TRTY.EXE Program

Highlighted features of TRTY.EXE version 3001.00 include:

•Support for two serial ports simultaneously, in half or full duplex.

•Ability to run AMTOR, packet, or RTTY communication, in any combination of two modes.

•Support for Baudot and 7 or 8 bit ASCII, with baud rates of 45 to 9600.

•Software and hardware handshaking.

•User-selectable screen colors, text, background, window edges and borders.

•Configuration of files, recalled by name.

•Ability to assign different callsigns to each port.

•Option to set the program to BEEP when it recognizes your callsign.

•Full-screen editing.

•Scrolling option, through previously shown text.

•Ability to edit text in one window, while monitoring one or both ports in other windows.

•Compatibility with IBM PCs, clones, and the Zenith Z-100, with 300K RAM, and MS DOS or PC DOS versions 2.0 or higher.

When the program is booted, the logo screen, shown in the figure, is displayed. If this bothers you, it can be switched off. The split screen display is where the bulk of communicating is performed. Hitting the F1 key brings up the HELP menu. This menu leads to a variety of submenus for both help and editing program features.

A look at some of the specifics of this program makes you realize what a finely honed tool it is. For example, TRTY supports 3rd and 4th level Baudot. This is a programming technique in which the full ASCII character set is represented in 5-bit Baudot, by using Blank-FIGS or Blank-LTRS combinations to indicate a shifted set. Received on a conventional teleprinter, normal Baudot is printed; received on another TRTY station, upper and lower case data can be exchanged.

There is also a RELAY mode, which allows remote stations access to relay messages through your station, without operator intervention. In this mode, a timer prevents messages from staying too long in the program's buffer, and ensures practical use of the feature.

Full keyboard remapping is also supported. This means, on one level, that any command normally assigned to a control key combination may be shifted as desired. Such a facility allows you to customize the command structure and syntax to suit both what you are used to (with other programs, for example) and what you find easy to remember. Hams speaking languages other than English may benefit from this by translating commands into their native language, which often changes the initial letter.

Remapping may go so far as to change any letter key, number key, or control combination on the keyboard. Thus, if an alternate key arrangement, whether it be alphabetic or Dvorak, is appealing to you, TRTY can accommodate your needs.

There are 26 callable strings per session, or 52 in all, which can be called individually or in tandem through the use of control sequences placed within the strings. Written in plain ASCII, these strings are limited to 80 characters each. But they may contain short, usually two-character, control sequences to insert a callsign, carriage return, a fancy margin, another string, a transmitter turn-on signal, or some other function.

Remote control of another station, through a relay, is even possible, through the use of a WRU (Who Are You) function, as long as all stations involved are using TRTY or one of its variants.

Tested with many packet TNCs and AMTOR setups, this appears to be quite a powerful package. A listen across 80 and 20 meter RTTY the other night turned up several stations using TRTY, and several more discussing it. My kudos to T.L. Vinson and the members of the Heathkit Amateur Radio Net for making this program available.

You can get your very own copy of TRTY from several sources. Certainly, the easiest way would be from another ham, or a ham club. Lacking that, the program is available both on CompuServe HamNet, and also on Delphi, where it may be found in the PC Forum, telecommunications library; and the Hobby Forum, Ham library. If all else fails, I will provide a copy to readers of this column who send me a disk, either 5¼" or 3½", a stamped, self-addressed disk mailer, and two dollars, to the above address. This will be for a limited time only, and as my schedule permits.

```

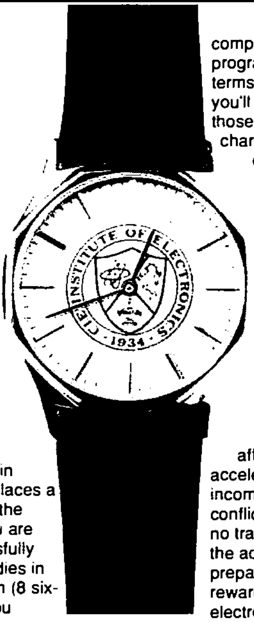
Figure. The opening logo screen of TRTY, version 3001.0.

We've got a lot in the hopper over here. A few more pieces of software, and a few more updates from things gone by. But I can always use more. Keep those comments and suggestions coming, by mail, to the above address, or via CompuServe (ppn 75036,2501) or Delphi (username MARCWA3AJR). 73

Tick. Tick. Tick.



That familiar adage, time is money, means just that at CIE. CIE makes it possible for students who can study at an accelerated pace to realize significant savings off the cost of an Associate Degree in Electronics. CIE places a restriction only on the maximum time you are allowed to successfully complete your studies in our A.A.S. program (8 six-month terms). If you complete the entire program in two terms, three terms...or seven terms you'll only be charged for those terms... no additional charges for books, lab equipment, or lesson programs.

At CIE, the world leader in electronics home-study, you'll learn from the best and you'll learn at your own pace in your own home at a very affordable price (even more affordable at an accelerated pace). No income interruptions, no conflicting class schedules, no traffic, no hassles, just the academic curriculum to prepare you for a richly rewarding career in electronics.

Mir on Packet

Since late January, the callsigns U2MIR and U2MIR-1 have been covering the Earth with FM packet signals from the Soviet Mir Space Station. This activity was not expected until March, but there have been no complaints. Signals have been very strong, although Musa Manarov (U2MIR) turns the power down to 2 watts when the system is running unattended.

How to Hear and Copy U2MIR

Any station that is packet-ready, with a synthesized 2 meter transceiver, can hear Mir and display packet activity from the space station. HTs with rubber ducky antennas are usually insufficient for two-way contacts, but with a slightly better antenna they can at least provide good copy. Several hams have established "connects" with the onboard BBS (U2MIR-1) using mobile packet stations with at least 10 watts to whip antennas.

Mir operates on 145.55 MHz over the United States. Simultaneous activity can occur with the onboard BBS via U2MIR-1. Figure 1 shows an early example of BBS activity. (The system date and time had not been initialized, yielding "0's" for those parameters.)

Doppler shift causes signals to appear off-frequency for fast-moving objects like the space station. When Mir is approaching, the apparent frequency will be high by as much as 3.5 kHz. To counter this effect and get good copy of the incoming packets, your ground-based 2 meter rig should be set to 145.555 MHz for the beginning of any pass exceeding 20 degrees elevation. When Mir is at its closest approach, the frequency should be set to 145.55 MHz. As it heads for the opposite horizon, best copy will occur around 145.545 MHz. An FM rig with tuning increments less than 5 kHz, and a discriminator, can be continuously adjusted to give true centering on the signal from above.

Doppler shift also affects the uplink from a ground-based station. Unlike the U.S. space shuttle activity, there is no frequency offset for signals to space, but the Doppler effect will make uplink signals appear high in Musa's radio during approach, and low during departure. The easiest way to counter the effect is to transmit on 145.55 MHz, with deviation set no greater than 3 kHz. For those with frequency-agile radios, the transmitter can be set a few kHz low during approach, and a few kHz high as Mir leaves.

If the signal from aloft is heard 2 kHz above 145.55 MHz, then the transmitted signal should be 2 kHz below 145.55 MHz. For most passes, a setting of 145.55 MHz for both uplink and downlink will suffice, with minimal loss of packets. The example in Figure 1 was obtained with a simple mobile rig with 5 kHz tuning increments and a typical crossed yagi used for amateur satellite activity.

Tracking Mir is not as easy as tracking other hamsats. The space station is in a very low orbit with passes lasting no more than 12 minutes. For those with satellite tracking programs, the element sets defining the station's orbit must be updated on a weekly basis for high accuracy. Month-old data sets can give errors as much as 20 minutes off if the station has been reoriented. (The cosmonauts on Mir reposition the craft for docking with resupply ships, and to counter the effects of atmospheric drag.)

If you do not have a satellite tracking program, there have been several free offerings on various computer bulletin board systems. AMSAT, the Radio Amateur Satellite Corporation, sells many extremely good programs for several types of computers. Complexity ranges from InstantTrack for PC machines with at least EGA graphics, to simple HP-41 calculator-style programs, and everything in between. For information on the many offerings, call AMSAT's office at (301) 589-6062, or write to: AMSAT, P.O. Box 27, Washington DC 20044. Discounts are available for AMSAT members.

Getting current element sets for Mir used to be very difficult. Although NASA prediction bulletins are available for the asking, they are usually too outdated by the time they show up in the mail. The best source is AMSAT bulletins via packet radio. Every week, N3FKV puts together the latest element sets for the amateur satellites and sends them out through the packet network.

Most packet BBS's carry AMSAT News Service items, and the latest element sets. Two formats are supported: the standard "AMSAT" format, which lists each orbital parameter with the appropriate description, and the "two-line" format, which appears as a cryptic list of numbers. While the AMSAT format is accepted by most computer programs, it is most useful for those programs that do not allow automatic updating. Programs for older computers and calculators cannot support automatic updates. The two-line format is most appropriate for advanced software packages that recognize the location of the numbers in the listing and know where to place them in the element-set data strings. Either way, the end result is the same: Current orbital data is available and can be loaded and put to use within a day or two of its uploading into the packet BBS network.

In Figure 1, there is a line stating, "No third party mail allowed." This may mean that only messages for U2MIR or other cosmonauts are allowed on the system. Many times the BBS is off the air. Musa may have turned the ham equipment off for sleep periods or other reasons. He might even be available for voice contacts.

This new BBS in the sky is easy to hear and very popular. Don't be surprised when "connect" requests are met by "busy" signals, with the associated "disconnect" message. A lot of hams are monitoring 145.55 MHz and waiting for an opportunity to connect and try out their systems. QSLs for current Mir contacts should be sent to: UA6HZ, Valery Agabekov, Box 1, 375600 Yessentuki, USSR.

STS-37

The latest U.S. ham-in-space activity is about to take off with a full crew of ham astronauts. The most recent launch date information targets early April. Packet, voice, slow-scan TV and fast-scan TV experiments have been planned. A space-mobile to space-mobile voice or packet QSO from Mir to STS-37 is also a goal. For information on the system configuration and mission goals, see "SAREX-90, Ham-in-Space Shuttle Missions" by Tom Clark W3IWI, Ron Parise WA4SIR and Bill Tynan W3XO, *73*, May 1990, p. 9. Unlike Mir packet activity, the U.S. equipment typically uses a 600 kHz offset for uplink signals. For a downlink of 145.55 MHz, the uplink is 144.95 MHz. DO NOT call the shuttle on 145.55 MHz. ■

ABOVE AND BEYOND

VHF and Above Operation

C.L. Houghton WB6IGP
San Diego Microwave Group

San Diego CA 92119

Microwave Devices

I'd been planning to construct an RF sweeper for portable operation, mainly for use in a spectrum analyzer, but I didn't have the circuits for driving the wide-frequency YIG (Yttrium Iron Garnet) oscillator.

When the schematic was presented to me, and I'd picked up a surplus log amplifier (from a military radar test set) for the IF system, this project was off and running. The log IF amplifier, a key item in the spectrum analyzer, works at 160 MHz and gives the system 90 dB of dynamic range. The unit has 12 transistorized IF stages which feed a logarithmic diode summing network that feeds a video output amplifier. This output is the vertical input to the oscilloscope.

I bought my scope, a cardiac oscilloscope, at a local flea market for $5. It is battery-operated (12 volts) and has a very slow (long-persistence) trace, but a regular o-scope will work just fine.

YIG Description

YIG oscillators are, I feel, the "dilithium" crystals used in warp-drive oscillators from the future. The YIG crystal forms a highly polished, spherical microwave resonator less than 1/100" in diameter. It behaves like a resonant circuit coupled to an oscillator transistor, usually of common base configuration. The YIG sphere generates a very strong magnetic field about the main coil. By varying the strength of the magnetic field, you change the sphere's resonance and the oscillator's frequency.

The main coil consists of two large electromagnet coils on each side of the crystal chamber in series with the DC supply. This coil is polarized, with one DC positive lead for current drive input.

DC current from the main coil is applied at right angles to the sphere's microwave coupling loop. The YIG is fussy. If the current through the main coil is too high or too low, the circuit will not oscillate at all.

I do NOT suggest that you take a YIG apart to see what is going on inside. Although you can separate the magnetic poles in the main coil to look at the construction, to go any further requires extreme diligence.

Now there is both good news and bad news. The bad news is that these devices cost big bucks new, and you can't home-brew them. The good news is that you can get them from surplus in a frequency range from 1500 MHz to over 12 GHz. Low frequency YIGs cover just over 1 GHz, and high frequency YIGs can cover greater frequency ranges. They differ in the amount of current, from 150 mA to over 800 mA, they require to drive the magnets.

This main coil current is critical. My oscillator requires about 425 mA to begin oscillating (low frequency) and 580 mA (high frequency) to stop oscillating. Adjusting the current through the main coil from 430 to 550 mA produces a resultant CW frequency at whatever current setting you stop at between the stated limits.

Frequency adjustment of the YIG oscillators is linear and proportional to the magnetic current. My YIG, with a frequency range of 8 to 12.4 GHz and current requirement of 400 to 600 mA, was made by YIG-TEK. Frequency adjustment (magnetic) sensitivity is about 40 mA per GHz. Power output from YIG oscillators can typically vary from 10 to 100 mW. There are types of YIG's available that are not used in oscillators but rather couple in and out of the resonant sphere, or several spheres, forming a very wide-range tuned filter.

Probing the YIG

An ohmmeter revealed that the high current coil of my YIG-TEK 10 GHz measured 15 ohms. The DC bias input (oscillator and amplifier transistor power circuit) showed a high resistance and capacitor-charging characteristic. My YIG had a heater circuit of 100 ohms for the crystal.

The YIG crystal can have an additional, smaller coupling loop as the drive coil for modulation (the FM coil). It is 90 degrees offset to the oscillator coupling coil, and adds to the main coil's magnetic field.

The (oscillator) coil is coupled to the sphere and provides input to a single transistor-oscillator stage. In turn, the transistor drives a second-stage amplifier for higher output, as well as providing isolation to the oscillator stage, which reduces frequency pulling on the oscillator. Most YIG oscillators and filters are quite small, and use SMA coaxial connectors for RF connections.

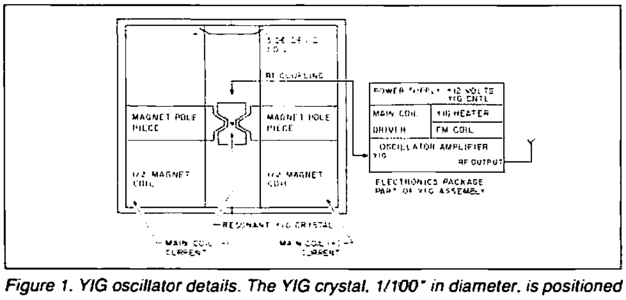

Figure 1. YIG oscillator details. The YIG crystal, 1/100" in diameter, is positioned close to magnetic pole pieces.

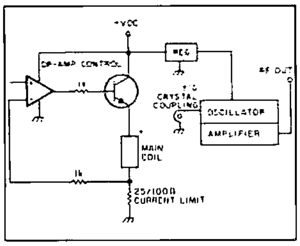

Figure 2. Basic YIG drive control circuit.

Power input to my YIG was via a DB-9 connector for all pinouts, making DC testing easy. The power connections are as follows: pin 1, +15V; pins 2 and 9, ground; pins 4 and 5, heater coil; pins 6 and 7, main high current coil; and pin 8, the FM coil input for modulation.

> **"This compact ramp generator has multiple applications."**

Some high precision types, perhaps designed for extreme conditions, have a heater in the cavity to maintain a stable environment for the YIG crystal. You don't have to connect this heater for microwave operation.

The circuit to drive a YIG includes your basic power supply with features to provide fine control. It can be made to sweep over the YIG's entire range, or be a CW source at a spot frequency. If you use it as a CW source, place a large electrolytic capacitor across the main magnet coil. The magnet coils are resonant at a very low frequency (below 30 kHz), and anything that helps swamp out the low frequency resonance improves stability. Glen N6GN gave me this little trick, and it really improves CW operation. (See Figure 1.)

John W7HQJ was willing to share the YIG driver circuits, which he assembled from multiple sources. John used three different YIGs in his sweep oscillator, which covers a broad frequency range of near-DC to 10 GHz: 0–2 GHz, 2–6 GHz and 6–10 GHz. While you might not build John's sweeper, with minor changes you can adapt his circuitry for a single YIG at any frequency.

The frequency range of 0 Hz–2 GHz is actually obtained from the 2–6 GHz YIG oscillator by limiting the sweep to 2–4 GHz and mixing a 2 GHz fixed oscillator, therefore producing a low mix product of DC–2 GHz. Of course, a small area from 0 to some MHz is not usable, due to rest frequency leakage in the RF filters. This arrangement might not give competition to Hewlett-Packard, but for our use it works just fine.

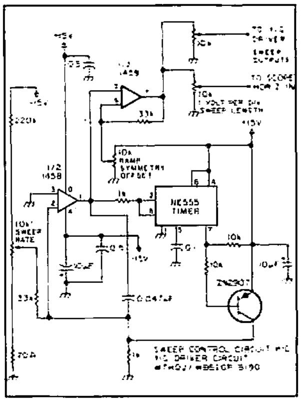

Figure 3. YIG sweeper circuit from W7HQJ.

The Sweep Ramp

This month I will go into the construction of the sweep ramp portion of the circuit. It provides sweep to both the YIG power supply control circuit and the oscilloscope horizontal drive external input. It only requires two op amps, a 1458 dual op amp, and a 555 timer chip, mounted "dead-bug" style (top of the IC glued to the board with the pins sticking up) on a single piece of PC board. The layout is helter-skelter, but easy with a little practice. Try not to stack up components one on top of the other; route leads between components in an orderly manner.

I usually start by soldering the ground pins to the foil, then adding bypass capacitors to ground on the power pins, giving the chip a support structure. Next I add secondary chips and inter-stage components between chips. You can develop a breadboard in a matter of minutes for testing. If the circuit is simple and the chips inexpensive, the breadboard might just be the final product!

This compact ramp generator has multiple applications. It offers clean sweep ramp, minimal noise output, good DC bus decoupling, variable sweep rate, adjustable offset voltage, and an output attenuator for driving an oscilloscope horizontal circuit. The YIG driver will work with almost any current range YIG. John mentioned that he has used this circuit with YIGs requiring from 60 to 800 mA.

The sweep ramp generator provides adjustments for variable sweep rates in sync with both outputs, one for the YIG driver and the other for the horizontal input of your oscilloscope. Controls for ramp symmetry and sweep length are also provided. Pin 7 of the 1458 op amp couples to both the oscilloscope's input and the power supply drive circuit. It is capable of producing a sweep ramp of +14 to −14 volts DC. A typical drive circuit is shown in Figure 2. Full details on this part of the circuit will be covered next month.

As always, I will be glad to answer any questions related to our VHF/UHF microwave bands or similar topics. Please send a SASE for prompt reply. 73's, Chuck WB6IGP

Avoiding the Slammer

Last Saturday night, I fell into the dragnet again.

WA6OPS and I, with ride-along observer Phil Gray KJ6UV, were cruising through downtown Fullerton. We had lost the hidden transmitter's 2 meter signal upon our descent from the starting hill, but that's not unusual. It was probably at least 20 miles away, and we planned to follow our original bearing until we got in range.

Hider Wes Printz KA3DSE announced on the 220 MHz coordination repeater that he would raise the hidden transmitter power briefly for a couple of late-arriving hunters. Good, maybe we can get another fix.

Wait a minute! What are those flashing lights behind me? I'm being stopped by the police!

Two cruisers were behind me as I stopped in a nearby parking lot. The officers were smiling as they approached the van. They flashed their lights all over the inside and outside as I offered my license. What a time for this to happen—there goes our chance to get another bearing.

These wide-eyed cops were the youngest rookies I had ever seen. They looked just like the Police Explorer Scouts we see doing traffic control duty at public service events. They seemed to be in awe of the 4-element quad on top of the van, with the mast going through the roof.

"What did I do?" I asked, as April offered one of them a copy of my T-hunt information sheet.

"Nothing," was the reply. "We just wanted to see if you had a scanner in there."

"Why?" I asked, silently wondering if he recognized the Regency MX-7000 on top of the dash, hooked to the Roanoke Doppler DF box. It has only ham frequencies in it, of course. (Well, mostly.)

"We've had a lot of burglaries," the neophyte cop says, "and it's illegal to have a scanner in your car."

That was my cue to give him a friendly briefing on the fun and usefulness of competitive radio direction finding (RDF). I also pointed out that we weren't listening to his frequencies, but it would not be illegal to do so in California. One of them disappeared for a minute. After a check on the radio with the Watch Commander, he sheepishly admitted I was right about the scanners and sent us on our way. Well, at least now we had a good excuse for finishing second in the hunt.

Getting stopped in the city during a T-hunt is very unusual here in laid-back Southern California, where VHF hunts have been going on for 35 years or so. Veteran officers are used to our strange antenna arrays and slightly erratic driving. They give friendly waves as they pass by the hilltop starting points lined with hunters' vehicles, and usually ignore the fact that a couple of them protrude into the traffic lanes. Normally, it takes something blatant to get them to pull you over—like the hunter who backed down a freeway on-ramp a few years ago.

It was different in the early days. Ken Walsh K6ZRL remembers the 2 meter hunts of 1960, complete with Gonset Communicators and dynamotor B+ supplies. One night, he and several other hunters found themselves under arrest, albeit briefly. They weren't doing anything illegal, but a homeowner had complained about the strange people with radio gear tramping through the countryside. One hot-shot officer crashed his patrol car in the fog during that caper.

Worried residents still call in, but now dispatchers call the helicopter patrol to check out the scene. Several times, my hiding spots have been in the spotlight from above. Usually Angel (that's what they call the chopper) hovers just long enough to give away the spot to the close hunting teams (drat!), and then disappears.

Occasionally, it gets dicey. Four years ago, April and I hid at the site of a new home that was being built in Anaheim Hills by its owners, a couple of our friends. These folks discovered at the last minute that they couldn't be there to hide with us. We decided to go ahead anyway.

After a dozen hunters converged on the place, it wasn't long before the chopper and spotlight arrived, followed shortly by a patrol car. The neighbor who called in came over to insist that we were trespassing. We had no proof that the owners had given permission. There was a hurried autopatch call to the owners—no answer. Eventually we prevailed, but we learned an important lesson: When hiding on private property, be able to prove that it's okay to be there.

By the way, that was a great hunt from a technical standpoint. The AC wiring for the house was complete, except that there was no breaker box, and no lines to the power company. We connected the output of the fraction-watt transmitter to one of the long Romex cables, then buried the transmitter next to the foundation (see Photo A).

You have probably seen the ads: "Turn all your house wiring into a giant antenna!" That's just what happened. Everyone DFed their way to the house with no problem. Then they wandered around the property for hours trying to identify the antenna. (No wonder the neighbor panicked.) "All the outlet boxes sure are hot," they kept saying. Yup.

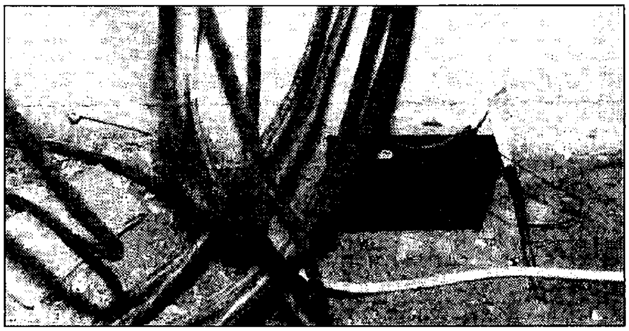

Photo. We've hooked the house wiring to the mini-transmitter's output, and now we'll bury it next to the foundation. It's going to be a great April Fool foxhunt.

Befriend a Cop

Consulting with the authorities ahead of time can pay dividends. One night we hid the little rig in an outhouse (that's right, a rent-a-biffy) in a new construction area in Yorba Linda. While setting up, we made friends with the security guard at the site. He got so enthusiastic about our prank that he let us use one of the vacant houses as a lookout post and hide our car in its garage.

For a while, Orange County hunt rules recommended advance notice to the police of the transmitter's location, so the dispatchers could reassure concerned citizens who called in to report strange sightings. That practice didn't last long. It was a lot of bother, and there was suspicion that advance hiding spot information was finding its way to some of the hunters. (I think I would have been tempted to "plant" some false stories when hiding, to see what happened.)

Certainly there are enough hams with police connections to make me think twice before disclosing my clever hiding spots. It was only two years ago that Don Lewis KF6GQ put on a hunt with the low power transmitter in a box under the reception desk at the Monrovia Police Station! All the bearings from every outside corner of the building pointed inside, of course. But, it took a lot of courage to walk through the door with a handheld "sniffer" to probe the lobby of a precinct house.

Get the Burper

Peace officers depend on their radio equipment, so they should be able to appreciate the need for RDF. Dean Hale KF7CR sent in a clipping from the Eugene (Oregon) Register-Guard, describing the antics of "The Belcher," who has been annoying the users of police and tow truck radios in 11 communities in the Monongahela Valley of Pennsylvania. He has whistled, made body sounds, and even played "Jingle Bells" on a kazoo.

So far, "The Belcher" has managed to elude DFers from the FCC's Philadelphia field office. Pennsylvania T-hunters, are you listening?

200 Hunts a Day

Bob Howle WA4ZID has an idea how T-hunters could perform a public service, save taxpayers' dollars, and add to our foxhunting fun, all at once. It all started when he discovered a 6" x 6" x 18" box in deep woods on his 20 acre property. It turned out to be the electronics package from a weather balloon.

Later, Bob had a chance to visit the National Weather Service (NWS) office in Jackson, Mississippi. He learned that two NWS offices in each state launch radiosonde weather instruments daily at 1100 and at 2300 UTC.

Bob writes: "These instrument packages are carried aloft by a helium-filled balloon and can attain an altitude of around 96,000 feet. Telemetry is transmitted back to a receiving station by an on-board transmitter that operates near 1680 MHz."

"To me," continues WA4ZID, "this translates into 200 opportunities per day to T-hunt! By finding and returning the radiosonde packages to the weather service for reuse, we could all do our part to reduce government spending (or at least get some enjoyment from same). Another benefit to DFing radiosonde transmitters would be that no one has to hide the transmitter."

Bob goes on to ask for information on directional antennas and receivers suitable for DFing these balloon-borne rigs. He suggests using a downconverter driving a 2 meter receiver. Perhaps a 1.2 GHz ATV converter could be modified for this purpose. [Ed. note: Radiosondes have been successfully DFed using a R-7000 in wide band FM mode and a small beam or dish.]

DFing transmitters, as they fall from the sky, can be an exciting challenge, as *73*'s editor, Bill Brown WB8ELK, and those who have participated in his ATV balloon experiments, can attest. The NWS radiosondes transmit a 400 mW AM or wideband FM telemetry signal to quarter wave vertical whip.

After the balloon reaches maximum altitude, it breaks and the payload parachutes back to Earth. This descent period (30–45 minutes) is the optimum window of opportunity for RDF. The range of a low power transmitter at 1680 MHz is limited once it hits the ground, unless you are lucky enough to be DFing from an aircraft. The batteries last about 3 to 4 hours, so you should have about an hour or two to locate the sonde.

So Uncle Sam is hiding transmitters for us. But radiosonde hunters (R-hunters?) will have to get a fix and get within "sniffing" range before impact. What a challenge! Do you think it's worth trying? Let me know. 73

The Universal Transmitter

If you have been keeping up with the QRP column these last few months, you should have two very useful pieces of equipment in your shack: the T/R controller and perhaps a Drake receiver capable of receiving some WARC bands. All you need now is a universal transmitter. Well, don't you know, that is exactly what we'll be building this month.

The transmitter is a lot different from some of the designs I've had in the past. It features five active transistors, your choice of either VXO or crystal control of the transmit frequency, a keying transistor for easy hookup, and three-stage output filtering for a really clean signal.

Most of the parts are easy to obtain. In fact, a lot of them can be purchased from your local Radio Shack store. The only problem parts will be the toroids. You can mail-order them from several companies advertising here in *73 Magazine.* There is plenty of room for substitutions of parts, so you don't have to sweat too much if you don't have a 47 pF cap. A 33 pF will work just as well. Just don't get too carried away when changing part values. The only values you should not mess with at all are output filter capacitors, of course. Not unless you want to change bands!

Output and Coverage

The transmitter will cover 3.5 to 21.0 MHz with no problem. Ten meters might be some trouble if you get a soft crystal. VXO of the crystal is possible, the only restraint being that you MUST isolate the VXO capacitor from ground. This requires an isolating mount and coupling shaft. Junk box stuff will work great. I'll tell you how I did my mounting in a little bit.

The transmitter will produce about 1.5 watts of RF. A little more or a little less, depending on supply voltage, crystal activity, and band. The lower frequencies will produce more bang than the higher frequencies because of the gain of the transistor used. My version of the transmitter drew 220 mA of current at 12.5 volts. At the time, I was using an old FT-243 crystal on 40 meters into a 50 ohm dummy load.

Four Stages

Let's look at how the universal transmitter works. There are four stages to the transmitter. An oscillator, a buffer, a driver, and the final or PA stage.

A Pierce oscillator is built around a bipolar transistor. Simple and very easy to get running. In fact, I changed a lot of the values in the oscillator and the thing still worked. The only critical part is the coupling capacitor to the buffer. You don't want to use too large a capacitor here or you'll load down the oscillator to the point of stopping it.

The next two stages, the buffer/driver, work together. Again, simple bipolar transistors are used. Transistor Q2 has some negative feedback to keep things stable. Emitter current is limited by the 100 ohm resistors in each emitter lead. The buffer transistor Q2 has an extra 10 ohms to keep the gain down a tad. Voltage to Q2 is supplied via the 250 µH choke. You can use either a commercially-made choke—any of the Miller mini-series will work here—or you can wind your own. To do this, use 18 turns of #28 on an FT37-43 toroid core. The small resistors in the supply line to both Q2 and Q3 act as cheap RF chokes.

Both stages are turned on via Q5, a PNP switching transistor. Grounding the base lead turns on the transistor and applies +12 volts to the buffer and the driver. The oscillator runs all the time and is not keyed. The 0.1 µF capacitor on the base of Q5 softens the keying. You can add to or reduce the value of this capacitor to suit your liking. The transmitter keys very well with the value shown, but it may be a bit too soft for some people.

The driver can be configured as either tuned or broadbanded. If you include the 10–60 pF trimmer on the collector of Q3, you can tune the stage for maximum power (with the best CW note). As you might well know, changing bands will require changing the number of turns, and the core type, if you go with the tuned circuit. On the other hand, if you leave the capacitor out of the circuit, and keep L4 and L5 (L4, 35 turns #26; L5, 4 turns #26) as is, the circuit is quite broadbanded. To change bands is really easy. Just change crystals and output filters.

The PA is simple and easy to get running. A 36 volt zener diode keeps the PA transistor from being zapped should the antenna not be connected to the transmitter. A three-pole filter provides excellent filtering of the output signal. RF decoupling is provided by the combination of RFC3 and the associated capacitors. The 100 µH RF choke is an off-the-wall part from Radio Shack. Without question, you could dig out the calculator and number-crunch the values and come out with an exact value of the RF choke. However, the one specified works fine.

Construction is easy, thanks in part to the fine PC board from FAR Circuits. The single-sided PC board shown here will operate just fine. The FAR board has a top ground-plane side to add a little extra stability. When using the FAR PC board be sure to connect the ground points together on both sides. Use what you have in the junk box. My PA transistor came from an old junk box CB.

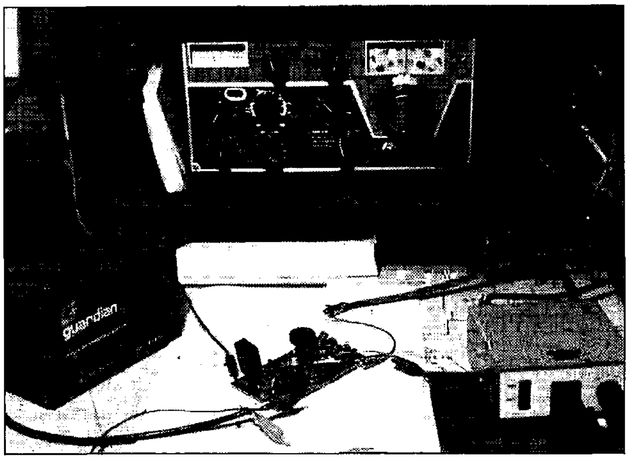

Photo. The universal QRP transmiter.

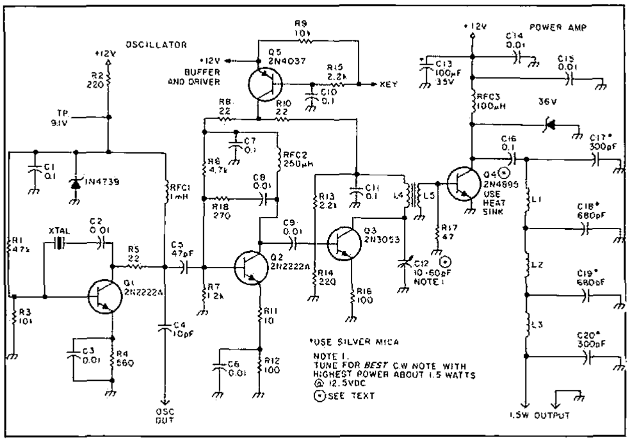

Figure 1. Schematic diagram of the universal QRP transmitter.

First, the Oscillator

If this is your first transmitter project, go slow and check each stage before going on to the next. There is little to gain by troubleshooting the entire transmitter if you can't get the oscillator to run. So, build the oscillator first. Stuff the board with the parts surrounding Q1. Connect the transmitter to +12 volts, and with the spot switch closed, check for 9.1 volts at the junction of the zener diode and the 220 ohm resistor. If all is as it should be, add the crystal. By using either a frequency counter coupled to the collector of Q1 (or taken from the 10 pF capacitor at the junction of the 22 ohm resistor and the 47 pF cap), or the station receiver, listen for the crystal's frequency.

Continue with the buffer/driver stage. Check for +12 volts at the collectors of both Q2 and Q3 when applying a ground to the key jack. Stuff the board now with the PA transistor and the output filter. With the output terminated into a 50 ohm dummy load via a QRP wattmeter (you do have one, don't you?) apply +12 to the board and

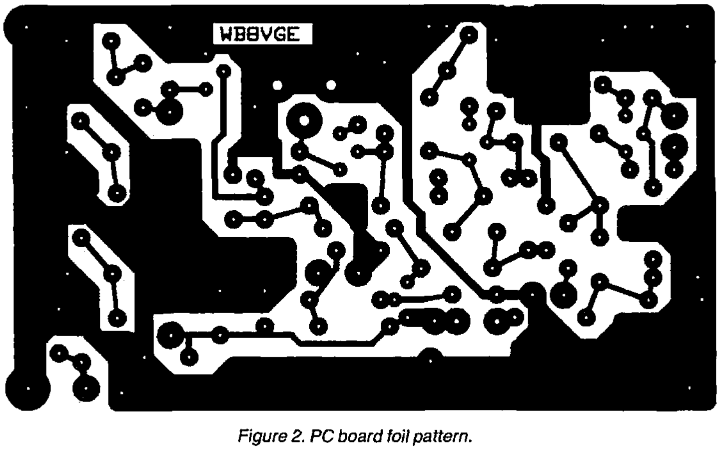

Figure 2. PC board foil pattern.

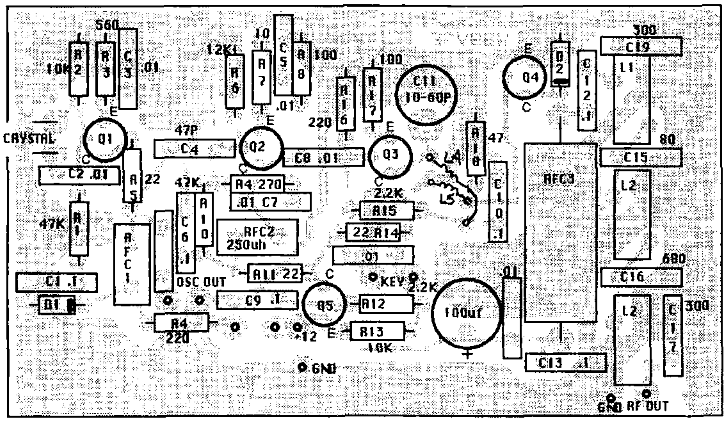

Figure 3. Parts placement.

key the transmitter. Using an insulated tuning tool, tweak the trimmer capacitor on the collector of Q3 until you have some power showing.

Don't go for max power, but rather for best power out with the best sounding tone. With a little bit of luck, you'll have about one watt or so of RF. Listen to the signal in the station receiver. It should be nice and clean without chirps, buzzes, or other noises.

If you built your version broadbanded, there will be no trimmer cap to adjust. Just add a crystal and go.

Receiving Adjustments

Before we run off this month, some notes about the transmitter. Since the oscillator is running all the time, you can hear the oscillator in the receiver. This makes it nearly impossible to hear a station calling us. So, the T/R controller will supply the +12 volts to the oscillator when you hit the CW key. If you are not using the T/R controller featured in the February issue, you need some means of turning off the oscillator during receive. For spotting the transmitter, a switch passes +12 volts to the oscillator. You can zero-beat to this signal without having to put a signal out on the band.

The small coupling capacitor from the oscillator can be used to couple a frequency counter to add a digital readout. Or you can use this output for a direct conversion receiver. Just route this signal into the mixer of the DC receiver and you're on your way to a transceiver.

To VXO the transmitter, add a 365 pF variable capacitor in series with the crystal. You don't have to remove the 0.01 µF capacitor from the board, since it seems to work the same with or without this capacitor. If you do remove it, you must place a jumper in its place. The capacitor MUST be isolated from ground. A small piece of plastic will work. The capacitor shaft must also be isolated from ground. I used a coupling shaft and a ¼-inch plastic rod. The main VXO tuning knob is connected to this plastic rod; not fancy, but it works!

All and all, this is a very nice transmitter to build and get running. The second version I built with the parts I found on the workbench netted me three states on 30 meters in less than 15 minutes. All the switching was done by the T/R controller. I added a small relay inside the transmitter to switch in two different crystals. The VXO gives me about 5 kHz of movement. That's not much, and I'm sure it's the fault of the crystals.

One final note. After four years of work, the *HW-8 Handbook* is done!! Completely re-worked with lots of new modifications for the Heath HW series of QRP radios. Lots of new modifications for the HW-9. To get your hands on one, send $7.95 ($12.95 for DX airmail) to me at the address above. 73

Parts List

XTAL	40m frequency	R7	1.2k ¼W resistor
Q1,Q2	2N2222A transistor	R11	10 ohm ¼W resistor
Q3	2N3053 transistor	R12,R16	100 ohm ¼W resistor
Q4	2N4895 (or 2N3866)transistor	R13,R15	2.2k ¼W resistor
Q5	2N4037 transistor	R17	47 ohm ¼W resistor
D1	9.1 volt zener diode	R18	270 ohm 1.4W resistor
L1,L3	17 turns #22 wire on T50-2 toroid	C1,C7,C10, C11,C15,C16	0.1 µF ceramic capacitor
L2	19 turns #22 wire on T50-2 toroid		
L4	35 turns #26 wire on T50-2 toroid	C2,C3,C6, C8,C9,C14	0.01 µF ceramic capacitor
L5	4 turns #26 wire over L4		
RFC1	1 mH RF choke	C4	10 pF ceramic capacitor
RFC2	250 µH, 18 turns #28 on FT37-43 toroid	C5	47 pF ceramic capacitor
		C12	10–60 pF variable capacitor (* see text)
RFC3	100 µH, R.S.# 273-102		
R1	47k ¼W resistor	C13	100 µF/35V electrolytic capacitor
R2,R14	220 ohm ¼W resistor		
R3,R9	10k ¼W resistor	C17,C20	300 pF silver mica capacitor
R4	560 ohm ¼W resistor	C18,C19	680 pF silver mica capacitor
R5,R8,R10	22 ohm ¼W resistor		
R6	4.7k ¼W resistor	Misc: XTAL socket case & hardware	

Note: All values indicated are for 40 meters. Values for other bands will be listed in next month's column. A double-sided blank PC board is available for $6 + $1.50 postage from FAR Circuits, 18N640 Field Court, Dundee, IL 60118.

Amateur Software and Hardware for the Commodore User

ART-1: A complete interface system for send and receive on CW, RTTY (Baudot & ASCII) and AMTOR, for use with the Commodore 64/128 computer. Operating program on disk included. $199.00

AIR-1: A complete interface system for send and receive on CW, RTTY (Baudot & ASCII) and AMTOR, for use with Commodore VIC-20. Operating program in ROM. $99.95

SWL: A receive only cartridge for CW, RTTY (Baudot & ASCII) for use with Commodore 64/128. Operating program in ROM. $69.95

AIRDISK: An AIR-1 type operating program for use with your interface hardware. Both VIC-20 and C64/128 programs on one disk. $39.95

AIR-ROM: Cartridge version of AIRDISK for C64/128 only. $59.95

MORSE COACH: A complete teaching and testing program for learning the Morse code in a cartridge.
For C64 or C128. $49.95
VEC SPECIAL $39.95

INDUSTRIAL COMMUNICATION ENGINEERS, LTD.

Models 420 (250W) and 421 (5KW PEP) feature the lowest cutoff (-3db at 31mhz) of any filter ever built for this application, and their sharp attenuation slopes go to work on spurious products immediately above the 10 meter band, reaching a near block before the TV I.F. frequency of 41mhz. Most filters made in the past 30 years that we have sweep tested don't even begin to attenuate before 45mhz, making them nearly useless for some of the most delicate forms of interference caused to consumer services.

Better yet, the brute-tough, robust construction of 420 series units mean long term dependability for serious operators and station owners. Both filters are built in split rectangular chassis, mill-finished 1/8" thick aluminum with 1/4" thick RF containment walls. Feed through fittings are machined from teflon TFE. Capacitor sections sheared from Phosphor-Bronze plate stock, smoothed & finished, and also Teflon insulated (421). Through coils wound from 3/16" copper tubing.

Both units feature all stainless steel ground fittings and construction hardware, have extended bottom plates for mounting, and are individually boxed with mounting screws, slip-off connector covers, and manual.

Notes from FN42

Ah! April has finally arrived. Here in New England that means we've made it through the winter and have come into the "mud season." It also means that it's time to start working on the antenna projects we've been planning all winter. And soon, Bill Brown WB8ELK, our resident ham balloonist, will be preparing for more balloon launches from the **73** *parking lot* [A sure sign of spring -the Ed.]. *Field Day is just around the corner, and the summer flea markets will be opening their gates.*

I hope those of you in the Southern Hemisphere, where summer is turning into fall, have had lots of fun with ham projects. If you did something special, why not write it up and send it to 73, either to me or the editorial staff? You don't have to be a Hambassador to get your name in print. Don't wait until tomorrow, do it today.—Arnie N1BAC.

DXpedition to Malpelo Island

Submitted by Ricardo Trujillo Velez HK4BHA. Last November some members of the Colombian Radio Amateur League went on a DXpedition to Malpelo Island. It took four days of hard work to pack the 10 tons of food, gas, generators, and amateur radio equipment.

The group onboard *Sebastian de Belalcazar*, a venerable ship of WWII vintage, arrived at Malpelo at 2 a.m., November 1, 1990, after 36 hours of travel. At exactly 0000 UTC on November 3, three of the planned five stations were operating. We continued operating until 1100 UTC on November 8.

On the steep side of the island, we set up the "top station on the rock" to take advantage of propagation toward the U.S. West Coast and Japan. As soon as Beto HK3DDD, Jorge KH6BDX, and Tibe HK4HHG turned on the IC-765, the JAs were booming. From that moment on, it was a solid pile-up (at times, 50 kHz wide).

Rigs used on the expedition were the IC-765, which performed flawlessly except for a blown fuse and an erratic keyer. The linear amplifiers used for 80 and 160 meters, Kenwood TL-922As, also worked fine, except for one of the 3-500Z tubes that developed a short and had to be disconnected. The TA-33M antennas were great. We lost part of one of them, and it became a TA-23M, but it still worked fine.

Ignacio HK3CC took equipment for satellite operation, including a HUGE box that contained all the antennas, fully assembled! Before getting on the ship, with a despairing Ignacio looking at us, we took the antennas apart and discarded two-thirds of the box.

When we had the satellite antennas set up, I tried to hit one of the repeaters on the Pacific coast, and after replacing a faulty connector on the downlink antennas and slowly turning the stack, I got an S-2 signal from 146.76 repeater at Horqueta mountain, near Cali, Colombia. With this link, we also had a big pile-up on the 2 meter band. Disobeying specific orders, I took my PK-232 with me, and had the opportunity to activate HK0TU on VHF packet.

After all the hard work, the results were just great! More than 40,000 QSOs. We worked 160, 80, 40, 20, 15, 10 and 2 meters. Modes were CW, phone, RTTY, and packet. We also worked OSCAR 13.

A week later, with the weariness slowly draining from our bodies, and the task of answering the QSL cards for more than 40,000 QSOs, we look back and ask: Would we do it again? The answer is definitely YES!

Always Fascinating Trindade Island

In a lucky mood, Tino PT7AA and Karl PS7KM got the Navy's call to go to Trindade Island just two days before the Light House Ship, *Almirante Graca Aranha*, departed on the usual trip of every two months, with supplies; and with mariners to change half the garrison of about 40 on a four-month duty period there.

Gathering all equipment and antennas and whatever else, running to their local airports praying for an extra place left free, and getting to the docks three or four hours later than specified by the Navy, after a last minute repair, the expeditioners got onboard just in time. . . after a 10-month planning period!

After an 80-hour trip, there it was, Trindade Island, where Tino and Karl disembarked from the ship's helicopter. . . . Lucky mood, as we say. . . .

We took our luggage to the meteorological station, the usual operating site on the island, and mounted the equipment and antennas so that at 1236 UTC June 11, we were able to have our first QSO, on 28 MHz, starting our log with OK3CCC, with ZY0TW for Tino and ZY0TK for Karl

As equipment, we took a Kenwood TS-130S, TS-430S, ICOM IC-725, two ground-planes for 10 to 40 meters, an inverted-vee for 10/15/20 meters, and another for 40/80/160 meters.

Even though the propagation was not so good, we were able to make 870 CW/SSB QSOs on 21 MHz, 809 on 14 MHz, and 560 on each 7 and 28 MHz, with 48 countries on CW and 57 countries on SSB. We would liked to have stayed longer, but the supply ship stays there for not more than two days, and we didn't feel that we could take two months, the time between supply ships, out of our busy schedules. So, radio amateurs have only six chances a year to get to Trindade Island, and those going on these trips are based on a waiting list. The waiting list is enormous with scientists, biologists, sociologists, oceanographers, and so on.

But afterall, if you get to Trindade Island, you'll have something really unforgettable to remember as long as you live. By the way, Trindade Island is also IOTA-SA 10 for the Islands On the Air Award.

Photo C. Tino ZY0TW at the key on Trindade Island, June 1990

4X90BS at the National Stamp Exhibition

During the Succoth holiday season this past fall, for eight days, Beer Sheva, the capital of the Negev, hosted the National Stamp Exhibition, an event of importance to every philatelist. 17,000 visitors graced the heavily guarded show of 3 million dollars worth of exhibits, which included rare stamps, the history of mail, and collections according to themes. Although not a stamp collector myself (I pass stamps from my QSLs to my wife's parents) *[Joyce at 73 gets mine from my letters!—Arnie]*, I was duly impressed by the scope of the displays.

The exhibit was opened by the Minister of Communications, the Mayor of Beer Sheva, the general manager of the Postal Service, and other dignitaries. Each day a new stamp was issued with first day covers available on location, and a special stamp was issued to commemorate the event.

During the duration of the exhibit, special station 4X90BS was on the air. Approximately 5,000 of the visitors took the trouble to go upstairs to visit the station. They received a leaflet explaining amateur radio and inviting them to get in touch with the Israel Amateur Radio Club to join our hobby. Thirty-five amateurs visited the station, some of them leaving their QSL cards to decorate the wall.

Seven Beer Sheva hams kept the station going under the capable leadership of Shalom 4Z4UT, who must be commended for setting up the station and being on hand almost all the time. Four thousand QSOs were logged with stations all over the world. Band conditions were really hopping, as witnessed by contacts with California on 10 meters!

On the opening day of the exhibition, Minister of Communications Pinchasi visited the station, and was seated in front of the rig and photographed. Yehiel 4X6YA prevented him from speaking into the microphone, politely explaining to the Minister that only a licensed amateur may talk over the air! *[Looks like a new amateur candidate, Ron!—Arnie]* The QSL card depicts the old and new Beer Sheva, city of 130,000. At the top is the bridge over the Nahal Beer Sheva river bed, in the center ground is the new city, and in the foreground is the well of the Biblical patriarch, Abraham. This card is sent out in reply to all QSLs received. Those wishing QSLs sent directly, instead of through the bureau, should QSL via 4Z4UT and enclose return postage.

Photo E. Some of the operators at 4X90BS. Rear (left to right): 4Z4UT, 4Z9GAG, 4X6YY, and 4X6EA; front: Ziv (SWL), 4X6DE, 4X1MK (73 Hambassador), and 4X6YY's son.

Wine Cellar Operation As in past years, during the Easter/Passover vacation, the Israel Amateur Radio Club is conducting a special 100-hour operation on all bands, on SSB and CW. This year, look out for stations operating from Israel's wineries! They will be on the air from Sunday, March 31, at 0600 UTC through Wednesday, April 3, to 1000 UTC. We expect three stations: at Golan Vineries in Katzrin in the North, Carmel vineries at Rishon Le'Zion, and the wine cellar of Zikhron Yaakov.

Special callsigns, unknown at present, will be used, and a certificate will be available for those working all three stations. As soon as final details are known, "73 International" will be notified. It is possible that a small sample bottle will go along with the award! *[Looks like many hams will be busy on the bands during those few days! Me too!]* 73

SG-230
SMARTUNER
HF ANTENNA COUPLER—SSB, AM, CW & DATA
FAST—INTELLIGENT—ACCURATE
OPERATES WITH ANY HF TRANSCEIVER

The *Smartuner* high technology coupler intelligently tunes any length antenna (8 to 80 ft) in the HF band. This unit will operate with any HF transceiver within its' specifications. The *Smartuner* switches 64 input and 32 output capacitance combinations plus 256 inductance combinations in a "pi" network resulting in over a half-million different ways to ensure a perfect match for the transceiver. And, *it remembers the frequency and the tuning values* and will re-select these values in less than 10 ms next time you transmit on that frequency.

SPECIAL HAM PRICE: $555.00

Gordon West, WB6NOA, "the Smartuner is the best coupler I've ever tested or used"

Hamfesting!

Ah, at last spring is nearly here. Some folks love the warm weather, the twittering of the birds, or the new flowers thrusting eagerly toward the sun. But we hams know better—spring means hamfests are coming!

While a good hamfest has plenty of variety, including parties, forums and lectures, the center of attraction is always the flea market. For many, myself included, nothing in all hamdom feels as good as getting that great bargain. (And nothing feels as bad as getting it home and discovering that it's a disaster!)

Of course, it's also fun to sell off your own junque to make room for the new junque you're about to buy. So, let's take a look at these activities, from both practical and technical points of view.

It's Your Move

Hamfesting is like chess. You want to sell your stuff for a good price, and buy stuff as cheaply as you can. Of course, the other guy wants to do the same thing. But money isn't the only consideration.

Before you sell a piece of gear, ask yourself: Do I really want to sell this? There are plenty of reasons to sell something, such as:

1) I need the money to buy something else.
2) It doesn't work and I can't fix it and I don't want to pay to have it fixed.
3) I just don't use it anymore.

Reason number one is the worst one. If you like the thing, don't sell it, especially if it is not easily replaced. For example, I have an ICOM IC-202 2 meter sideband portable rig I got several years ago at a hamfest. Here in northern Vermont, there is practically no 2 meter SSB activity. I have made maybe three contacts on the rig in as many years. But 202s are getting quite hard to find, so I know if I sell it, I may never be able to replace it. Heck, I might not live here forever, and my next QTH could be brimming with VHF SSB. So, here it stays. Of course, if I didn't like the rig, that would be another story.

If you can't fix something and don't want to pay to have it fixed, then by all means sell it, but tell the truth, please. Don't say it works great when, in fact, it is deader than the proverbial doornail. Sure, some hams will be scared off by its nonfunctional status, but others will jump at the challenge, especially if the price is right. The majority of the stuff I buy at hamfests is broken and cheap. For me, fixing and using gear given up for dead is one of the most enjoyable parts of the hobby. In fact, I highly recommend it as a learning tool, if you're so inclined. Also, once you set it straight, you can turn around and sell it at the next 'fest, making a few bucks in the process.

If you have a nice radio but just don't need or use it, and you're sure you won't miss it, selling it might not be a bad idea. At some hamfests, you can get good money for nice gear. At others, though, nobody comes with large amounts of cash, so you may sit all day trying to sell an $800 rig. Before you waste your time, ask around about the nature of whatever 'fest you're going to.

By the way, you will have a much better time if you go with someone else, because one of you can watch your table while the other one goes scouting around. *Never* leave your stuff unattended. Hams may, for the most part, be honest, but some are not *that* honest.

How Much Ya Want Fer That?

Once you've sold your extra gear, your wallet should be stuffed, and you will want to get to the really fun part: buying. Sometimes, you go to the 'fest looking for something in particular, and other times, you just browse. Let's look at the different kinds of things you can buy.

Parts is Parts

If you home-brew or do much repair, you need to keep a stock of parts on hand. Sure, you can get some of what you need at Radio Shack, but you'll pay retail prices, and their selection of components is limited, so you may not find what you need. Hamfests are a great place to stock up.

Most of the larger 'fests I've been to have a few people selling parts from plastic bins. The parts are new surplus, and the prices are low, low, low. I've gotten everything from resistors and caps to FETs and ICs. Almost always, the parts have been fine.

Be wary, though, of surplus electrolytic capacitors, especially big ones. Take a good look at them before you buy. If they look old or corroded at all, steer clear. Those things just don't hold up well on the shelf.

You will probably also find some unusual parts, like air variable caps, toroids, waveguides, tubes, etc. Many of these parts have such a limited market that they have all but disappeared, even at mail order outlets. And, of course, if you need a specific part for an older ham rig, the hamfest may be your only choice.

By the way, I always go to the parts bins last, because the primary hamfest rule, "Grab it when you see it, or it will be gone," doesn't usually apply here.

Computer boards, especially expansion and I/O boards for IBM-type machines, are showing up more and more. Apple II stuff is common, too. Even hard disk drives are being offered, although I'd be leery, given their rather fragile nature. RAM ICs, floppy controllers and other roll-your-own computer parts, right on up to complete motherboards and whole machines, are in great supply.

Respect for the Dead

The other great source of hamfest parts, of course, is dead gear. There's always lots of that around. Sometimes, you can pick up an old, dead rig for $2 and get a $20 part from it! If you know what you're looking for, it's a great way to go. I often buy dead VCRs, because they are loaded with good stuff and can be had for as little as $5. Heck, the headwheels are worth 10 times that alone. Occasionally, I even fix the machines and use them, but they make great parts sources for coils, caps, Japanese transistors, motors, etc.

Once in a while, you can buy something really cheap for parts, and then discover that it is easily fixed! I once bought a 15 watt synthesized 2 meter mobile rig with a nice DTMF mike for $25. The seller said it "won't transmit," so I figured on a blown final transistor at best, and serious damage at worst. I expected to use it either for parts or perhaps just for the mike, but when I got it home, I discovered that the only problem was a dirty TX/RX relay! I cleaned it and have been using the radio with no problems for almost five years now.

> ***"Hamfests are a great place to stock up."***

Need a tube? There are usually a few guys selling loads of them. You aren't likely to find a high-power transmitting tube (although it is not unknown), but there are lots of 12AX7s and the like to be had for very little cash. If you've priced tubes lately, you'll want to grab what you need at the 'fest. Some tubes may be new, but others will be used. Usually, the seller will be up front about that.

I Feel Lucky...

Buying a radio at a hamfest is always a risk. Unless you happen to know the seller, you have no idea what is inside. It could work fine, or it could be butchered and ruined by an incompetent service attempt. Typically, something will be wrong with it, but it may not be too bad. If you are technically oriented, it may be worth the gamble. If not, you are probably wisest to stay away. Naturally, if you can see the rig work, you know at least that it is not wrecked. Well, actually, not always. I once bought a walkie, at a fairly high price, after seeing it work. Ten minutes later it literally poured smoke out the bottom and died. The seller didn't care and wouldn't refund my money. Although his butcher job had mangled the radio, I ultimately rebuilt it to good-as-new status, but it was quite a mess, and I never would have bought it if I'd known. But such cases are rare. Usually, if it seems to work it probably does.

Look for obvious signs of sloppy tampering, such as stripped screws, solder burns, damaged cords, etc. Also, check to see if the rig is clean. If it is covered with cigarette residue (which is a sticky, yellow gunk), you can bet that the stuff is all over the inside, too. And, in my experience, heavy smokers tend to be the most careless with their equipment. I don't know why that is, but it seems to be so. As a general rule, try to stay away from dirty, abused-looking gear. A clean rig is more likely to be well maintained.

Ask if there's a manual included in the sale. Sometimes the seller will promise to mail it to you. He may do it, and he may not. I've bought some fairly expensive stuff and been unable to pry the manual from the previous owner. But I also remember a guy who spent $2 to send me the manual for a $5 purchase! What you want most, of course, is the schematic. If the rig is a common one, you can probably get it from the manufacturer or a local ham. If, on the other hand, you're buying a Hamatsitsi X-2900, made in 1974, you may be out of luck.

I'll Give You Three Shekels and a Lame Camel...

Bargaining is not the norm in America, but flea markets are an exception. Almost no one expects you to pay the asking price. If you have no idea what the gear is worth, ask around before you plunk your money down. If you really want the thing and need to decide in a hurry, you'll just have to wing it. You might get a popular, late model rig such as the FT-757GX for 10 to 30 percent less than the asking price. For an old, beat-up boat anchor or a dead chassis, try offering one-third and go from there. You'll be surprised at how often you can get real bargains if you're not shy about asking.

Although flea markets are sometimes called "swapmeets," very little actual trading goes on. Most transactions are for cash. But, sometimes a real trade can be had. If you've been unable to sell your own items, try offering them for what you want, especially near the end of the day. I once traded a color video camera, which had been sitting unsold all day, for a Macintosh computer. I then sold the computer 10 minutes later for exactly what I had been trying to get for the camera! Everybody went home happy.

Well, I know this month's column is a bit off my usual beaten path, but I hope this advice will help you enjoy the hamfest experience. If you've never been to a 'fest, you don't know true happiness until you've seen 8,000 people walking around with callsign hats and rubber duck antennas sticking out of their pockets. Enjoy! 73

Continued from page 4

While I'm sure that I'd have no problem in getting equipment donated, I'd rather see you pack up your own portable rigs and antennas that you know and take 'em over. This should be a people-to-people effort, not a commercial one.

Yes, of course I'll turn the promotional faucets on and make sure every newscaster is aware of what you're doing. With some good PR we might be able to attract tens of thousands of youngsters to amateur radio. At least we can make the general public aware that amateur radio exists and that it isn't just some kind of citizen's band offshoot.

I'm not talking CW or SSB here; I'm talking high speed message handling via RTTY and packet. We'll need stations on the American end in major Arab communities such as Brooklyn (NY), Lowell (MA), etc.

I've operated from the area—from Jordan, Lebanon, Syria, Iran and Afghanistan, so I'm familiar with the propagation. We should be able to relay messages from Iraq a good part of the day and night. We'll need some relay help from Europe part of the time. That's the nice part of digital communications—relaying is a snap.

I've initiated contacts with our government to see how interested they are in such an effort being organized and made ready for implementation. I think they'll like it because we're going to need all the people-to-people friendly contact we can make in order to cool off the Arab/American hostilities resulting from the war. Maybe you've noticed that the Palestinians aren't exactly cheering us on.

We'll need hams with laptop computers for message inputting. We'll need operators to keep the traffic moving around the clock. We'll need the capability to handle millions of messages, not thousands. I think we can do it.

My little Model 100 laptop would be fine for this action. It's simple to use—takes maybe five minutes to learn. It automatically counts message words and characters. It dumps to disk for message transfer to the rig's computer—probably another 100. Everything we need is small and portable enough to be carried over as luggage. I even have one Model 100 with packet built right into it.

If you're interested, let me know. In the meantime I'll see what I can do as far as working up the transportation and accreditation that'll be needed.

This will be the first real opportunity for us to provide a desperately needed high speed communications service—one which no other service can possibly handle—so I hope we're up to it. Not only can we do a lot of good toward repairing the war wounds and possibly helping ease general Arab/American tensions, but we can gain the visibility we need to assure our growth and preserve our bands. This could make the big difference we need at WARC in 1992.

How about the ARRL? Well, despite endless opportunities, they've never come through before, so it doesn't seem rational to bet everything we've got on their getting into action this time. When the big hurricane hit St. Lucia, the League never noticed. I packed up several suitcases of ham gear and sent 'em down with *73* editor Tim Daniel N8RK. Our effort helped the island get back on its feet.

I've got plenty to do without trying to organize an Iraq emergency communications system, so if the ARRL will actually do it—and will see that amateur radio gets the credit instead of the League—I'll be a solid supporter. I'm not going to hold my breath.

I'll be surprised if Baxter isn't all over this self-promotion opportunity with endless talk, reams of press releases and little action. We'll see.

My own agenda is to spend as much time as I can working toward my goals of improving independent music sales and getting a basic electronic educational course into our schools. It's just that this Iraq situation seems to provide an opportunity for amateur radio and America to both benefit.

Governments and bureaucratic organizations such as the ARRL tend to be difficult to get into action. When disturbed, they slowly move from the sleep mode to dither. If the pressure continues they'll move from dither to action. So we'll see. I want to see action, even if I have to do it. But that's a last resort.

How about you? Are you game for the adventure of your life? Or do I hear a bunch of throat clearing and foot shuffling? I noted that 95% of the Americans who signed up to go to Cannes for the recent music industry meeting canceled out in panic when the war started. Even class trips to Washington were canceled. Phooey.

Amateur radio provides many opportunities for adventure—opportunitites which are lost on most hams. Sad. There's adventurettes on mountaintop VHF expeditions. There's DXpeditions to Caribbean islands—even to tough ones like Navassa. Even hidden transmitter hunts and Field Day can be adventures.

It isn't the cost which is stopping most hams, for many of these adventures cost little. I explained how Sherry and I visited hams in Munich, Vienna, Krakow and Prague last year for under $1,000 complete. We've just gotten back from Cannes where we spent under $200 for everything, including the airfare, hotel and meals. No, it isn't the money; it's a shortage of the spirit of adventure that's keeping most hams at home.

How much does it cost to go on an African hunting safari? A fortune, right? Sure. Well, I talked two other adventurous hams into going with me on a two week safari in Kenya where we spent $690 each. We had a hunting trip none of us will ever forget. So how about a little visit to Baghdad, dad? It's a great city with beautiful mosques and a fascinating bazaar, if we haven't leveled too much of it. They'll really hook you on the taxi fares if you aren't careful, though.

Dayton? Again?

What is it that drives more than 30,000 hams to Dayton every April? Cars, trucks, motor homes, planes, RVs, motorcycles and even bicycles, that's what.

And what kind of homing instinct is it that forces otherwise crazy old men to drop everything in late April and home in on the Hara Arena on the outskirts of Dayton? What attraction is there that results in hundreds of convoys of vehicles, all sprouting weird antennas, heading in from all over the country?

Well, one attraction is the world's largest electronic flea market. There's everything there from 1920s' radios to WWIII surplus. Computer hackers have been known to lose bladder control over some of the hard disk bargains. It's a ham builder's heaven: parts, parts, used gear, modules, brand-new, old, ancient.

All the ham manufacturers are there, showing off their newest products. Ham dealers, with their razors honed, are ready to cut their competitors' throats. Their booths are hard to get to because there's always a swarm of fanatic price shoppers shuttling from dealer to dealer, working the price of some piece of gear down, dollar by dollar.

There's an ambulance on hand for hams who try dealers' patience beyond endurance... and for old-timers whose walkers have broken under the strain.

There are technical sessions for every imaginable facet of our hobby. The DXers get together and get their jollies over DXpedition videos. Indeed, one of the great attractions of Dayton is that it is the one big hamfest of the year where you can get together with others who are into your own special ham fetish.

The traffic handlers all reassure each other that it's everyone else that's crazy, not them. There's an ARRL forum which is oh, so carefully orchestrated so as not to allow any dissension to be evident. The MARS hams have in the past couple of years gotten together to commiserate over slackening military support. There's nothing like a nice war to perk up MARS, so this year we should see some smiling faces.

The slow-scanners, AMSAT, packet, RTTY, moonbounce and other groups all caucus at Dayton. The better heeled have hospitality rooms where they can get together and lie.

Yes, of course there's a Wayne Green forum. Every year a crowd gathers and I tell 'em the same thing. I explain how amateur radio is going to hell in a handbasket. Worse, I explain what happened to make it happen. You know, all the same things I write in my editorials. There seems to be no end of interest in my telling what I've written.

For some reason they keep coming back every year. Perhaps it's because they're all old and they need a memory refresh once a year to keep them going. Whatever it is, the Dayton Hamvention organizers tell me I pull the biggest audience of any forum every year.

If you'll let me know what you'd like me to talk about this year, I'll cover anything you like. I usually cover our slow growth and its effect on America. I explain what went wrong and who, exactly, did it. I then explain what we can do about it.

I do some blue sky about new technologies we can pioneer. We have so many possibilities for new modes that it's incredible. And the pioneers, if they do it right, can easily make zillions. I've personally known several youngsters who've done well recently... one is a billionaire now. Another is only worth a few hundred million. It's out there if you play your cards right.

I don't think you want me to get into any technical discussions of how electromagnetic fields can screw us up and increase our chances of getting a listing in *QST* (Silent Keys). Or an explanation of how the mind works, why it gets screwed up and how to fix it.

Sometimes I ask for a show of audience hands on various ham activities. How many are on packet? How many are DXers with over 300 countries confirmed? How many are active on 10 GHz? How many have been on a DXpedition? Things like that. It becomes obvious that we have a whole huge mansion of possibilities in amateur radio and most of us are living in one little closet and never even opening any doors.

This is why I sometimes may seem testy that over 40% of all hams have never even progressed to a General Class license. Yes, I've heard all the feeble excuses and rationalizations. Baloney. With kids of 10 making it through to Extra, we're not talking a rocket scientist achievement. Now why are you getting defensive when you know I'm right?

You know as well as I do that if you ever decided that you were going to go for an Advanced ticket, you could do it easily. It's like anything else—you have to make the decision, from there on it's easy. Decisions are difficult to make. I mean real decisions, ones you aren't going to change.

You can go on DXpeditions. You can lose 85 pounds. You can become an expert in a new technology. You can do this at 20, 40 or 60. You can become one of the best conversationalists we've got over the air. First comes the decision to do it. Then comes one heck of a lot of work. Nothing of value comes easy. And those of us who take the easy road end up with little of value ... in skills or accomplishments.

Hey, we're in need of good rocket scientists, so how about taking up that business? You don't go to school for it, you have to learn it all by yourself—like almost everything else.

Oh yes, Dayton. It's a madhouse. 30,000-plus hams, all with HTs on their belts. Two meters is jammed solid from one end to the other. It usually rains a little while on Saturday, chasing 20,000 inside and packing the exhibit areas solid until the sun comes out

again. Good time to eat popcorn and maybe a sloppy Joe.

Drop me a line, a fax or even leave a note for me at the *73* booth and let me know what you'd like me to cover in my talk. It'll be from 1:00 to 2:45 on Saturday. Now ask me if that's AM or PM. If it was an ARRL convention it would probably be AM. I shouldn't complain, for many years they wouldn't let me even exhibit at ARRL conventions, much less speak.

If you haven't done Dayton, don't miss another year. It's one of those experiences you'll never forget. I'll be all over the place, so watch for me and say hello. Tell you what, ask me for a "Buck-Off" worth a dollar toward any of Uncle Wayne's stuff. I'll have a pocket full to help prod you into spending some money. And you aren't going to miss my talk, are you? It's right after lunch on Saturday, so you can catch a short nap.

Wayne Makes Mistake!

Well, it had to happen! After 40 years of writing editorials I finally made a mistake. Sure, I've got a whole bunch of feeble excuses and rationalizations. But it comes down to a dumb mistake.

In my January editorial I had a nice picture of the Mobile (AL) Amateur Radio Club that I took while I was there giving a talk. I put 'em to sleep once a year when I'm in Mobile for my yearly USS Drum submarine reunion. It's a great club and they're doing wonderful work in getting youngsters licensed.

From Mobile I drove to New Orleans to look for a spot to take a good picture of Scott Kirby for the cover of his second Greener Pastures CD release. From this I managed to mislabel my club photo as being in New Orleans. Wasn't. I don't even know if they have a ham club in New Orleans. I know they sure won't talk to me over the local repeaters when I check in.

Scott's still playing every day on the streets in the French Quarter. If you get to New Orleans, say hello and put something in the hat, boy. He'll be coming up here to New Hampshire soon to record his third CD in our new state-of-the-art recording studios.

Yeah, I've gotten into the record business. My Greener Pastures Records label has issued three CDs (and cassettes) so far... two of Scott playing Scott Joplin's music and one bluegrass. My Adventures In Music label has 11 releases so far and is gearing up to put out four a month. My Auditions label has one CD almost out and a bunch more in the works. The music business is great fun and it's growing fast, despite the recession.

Anyway, I hope the Mobile club members will turn down the fires under that vat of tar and forgive me for screwing up. 73

HIGH PERFORMANCE PRESELECTOR-PREAMP

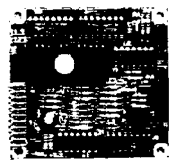
The solution to most interference, intermod, and desense problems in repeater systems.

- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N, BNC, and SO239 connector options

Typical rejection:
±600Khz @ 145 Mhz: 28db
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs)
± 5 Mhz @ 450 Mhz: 50db (60db GaAs)
±20 Mhz @ 800 Mhz: 65db
±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

How's the Weather?

Showing off the latest computer program or graphic creation has got to be one of the most popular ATV "programs." It's always fun to see the most recent computer goody displayed via ATV. Recently I ran across a computer program and service that really excited me since it incorporates a topic of great interest to hams: "the weather".

In previous columns we've talked about ATV repeaters that provide weather radar feeds from the National Weather Service (or from TV and radio stations). As the unsettled spring weather approaches us, it always pays to have an edge on Mother Nature. It's great to know just where those nasty storms are, and when to head for cover.

But what if you don't have a local weather radar feed available? Let's take a look at an alternative.

Enter WeatherBrief

It turns out that a computer dial-up service called WeatherBrief is available from a company called WeatherBank, Inc. The WeatherBrief service gets its information from the National Weather Service and supplies it to their customers in a readily usable form.

Other, similar services that I've investigated have cost incredible amounts of money for the initial software package along with an exorbitant connect time charge. They were really geared up for commercial forecasters. Fortunately, WeatherBrief came along to give the average home user forecasting capabilities that only your TV weatherman had in the past.

What makes WeatherBrief so unique is its really inexpensive software package (only $49) and very reasonable connection charge (as low as 20 cents/minute). In fact, some free connect time is included with the software price, making this a real bargain! They also have a toll-free dial-up number, but you'll pay more for the connect time (35 to 43 cents/minute depending on the time of day).

The WeatherBrief package gives you the ability to view all kinds of nicely done custom graphic weather maps for various regions of the country. This package runs on just about any IBM PC or compatible clone with an EGA or VGA graphics card.

One of the nicest things about the program is the ability to select just those items you want to look at. The program is designed to log onto the main number, grab the information you're looking for in the shortest possible connect time, and log you off. Once the information is in your computer, you're free to view the weather maps and save them to disk (PCX graphics format). Since all of the high-res color maps are already part of your program, only the weather data is transmitted over the phone lines, saving tremendous amounts of connect time. These are high-quality maps your local TV weatherman would be proud to display on the evening news! You'll have a great time showing off your very own weather forecasting station on ATV.

Available Maps

All kinds of weather maps can be brought up. Weather front information (both regional or national), cloud cover, jet stream location, real-time lightning strikes, precipitation (current or forecasted) as well as actual satellite images for three areas of the U.S., are also accessible.

Download time is quite fast, typically about 10 to 30 seconds at 2400 baud for each item selected. For example, I selected a weather front map, precipitation forecast, weather radar, and a lightning stike sequence. I received all these in under two minutes. Quite a bit of information for 40 cents of connect time. This quick download capability is

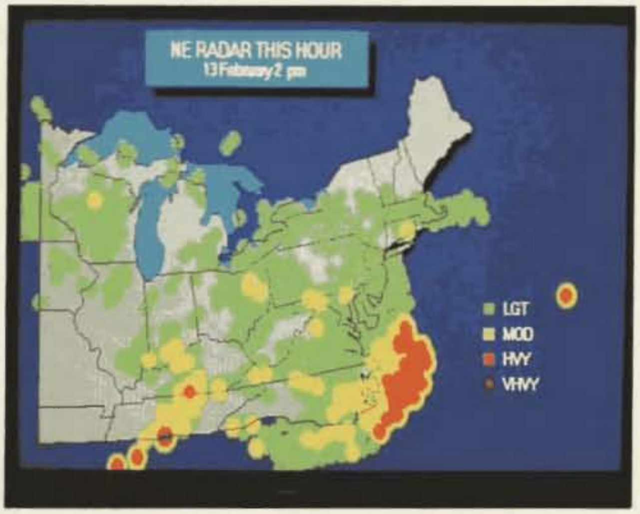

Photo A. Radar map of the northeast

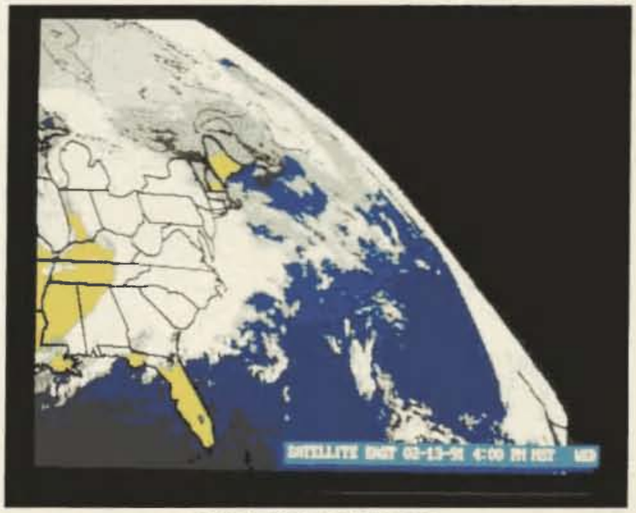

Photo C. Weather satellite map.

Photo B. Real-time lightning strikes over the southeast

Photo D. Map of the jet stream

due to the fact that the map graphics are already stored in your computer as part of the WeatherBrief software. Only the actual weather data needs to be retrieved. The only files which take a lot of time to download are the satellite images. These files are 30k plus in size and take about two to three minutes to download at 2400 baud. Also any custom map not already in your package can take some time as well. You can use a 1200 baud modem; it'll just take longer to download the information.

Once the information is in memory and you're offline, you can display the maps individually or in a continuous loop sequence.

One thing to note, however, is that these maps are divided up into either national or multi-state, regional coverage (not individual states or counties). Don't expect the weather radar screen resolution to equal that of a local weather radar feed. The resolution on the WeatherBrief maps is usually a 20 by 20 mile area. Their new version 4.0 does have the option of a single state map with 1 mile by 1 mile resolution. However there is a per month surcharge if you use this service.

ATV Uses

What can you do with this on ATV? Become your group's ATV weatherman! Know when weather trouble spots are approaching. Look at the weather radar map and real-time lightning strikes for your area, let your friends know when to unplug their antennas!

You can set up the latest version (4.0) of WeatherBrief to automatically dial-up for information periodically and display the results in a loop sequence. This would be a nice addition to any ATV repeater system. Set up a PC at the repeater site and let your whole group tune into the current weather.

Since certain weather patterns can be responsible for enhancement of UHF band conditions, try your hand at predicting the really big band openings! Hint: A clear, still and humid summer night in the Midwest with a big high pressure area stuck overhead is usually a winner.

For those of you really serious about studying temperature inversions, WeatherBrief allows you to access atmospheric sounding data from radiosonde flights nationwide. You can see the altitude and strength of the inversion just by reading this data. Also winds aloft forecasts and current wind profiles at various altitudes are obtainable in text format as well.

Where to Get It

If you can't find WeatherBrief at your local computer store, try calling Software Toolworks at (415) 883-3000, ext. 779. You can also order it from WeatherBank, Inc., 5 Triad Center, Suite 315, Salt Lake City UT 84180 or call (801) 530-3181. 73

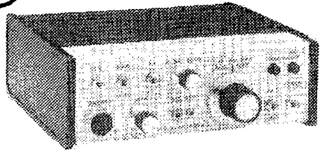
SMILE! YOU'RE ON TV



Only $329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

Current DX News

According to Karl PS7KM, the Natal DX Group will activate St. Peter and St. Paul Rocks in May 1991. The list of operators includes PS7KM, PT7AA, PY5AKW, PS7AB and DJ9ZB. Karl notes that the cost of the DXpedition will be $11,000.

Next item: *DX Around the World*, edited by Larry Cox WA6AIL, is a Braille reference manual available from San Diego Braille Transcribers Guild, Inc., 1807 Upas St., San Diego CA 92103. The 55-page manual lists the current DXCC countries by prefix and name, compass headings, distance, time differences, zones, etc. Sunspot cycles and the Solar Index are also discussed. The cost of the manual (for materials only) is $4.15 (on paper) or $7.40 (on plastic pages). Thanks, "Long Skip."

Special Canadian Prefixes. In March and April, to commemorate the 100th anniversary of Ukrainian settlements in Canada, the following prefixes may be used by Canadian amateurs: VA1-8 in VE1-8 call areas; VC1 and VC2 in VY1 and VY2; VC9 in VY9; and VO7 and VO8 in VO1 and VO2. Note: The VY9 prefix is allocated for use by the Canadian Department of Communications.

Additionally, special event station VA1ØØU will be active during this period on 10–80 meter CW and SSB (possibly some 160 meter activity too); 2 meter CW/SSB or FM upon request. QSLs for VA1ØØU go to VE3IPR. Thanks VE3IPR, editor of "Long Skip."

DXing in 1990: A Brief Review

There should be no doubt that 1990 was a great year for DX. Some very rare countries, that had not been active for several years, were activated; several new DXCC countries were created; and conditions were generally quite good. There were a few disappointments, too, such as the DXpedition to South Georgia and South Sandwich Islands, which was postponed, and no DX from Albania. Perhaps this year. . . .

Bouvet Island. The year began with a bang with the 3Y5X DXpedition to Bouvet Island, one of the rarest DX countries. 3Y5X was operated by LA1EE, LA2GV, F2CW, JF1IST and HB9AHL to the tune of more than 45,000 contacts (42.2% with stations in the U.S.).

Bangladesh. JA1UT, JA3UB and others ended Bangladesh's radio silence by operating as S21U.

Bhutan. Jim VK9NS, after several years of negotiations with the Bhutanese government, put Bhutan back on the air, making almost 15,000 contacts. He signed A51JS. He is planning to return to Bhutan during 1991 (probably in May). Other operations, promised for 1990 by other operators, never happened.

Southern Sudan. John PA3CXC led a group of operators to Southern Sudan and operated as PA3CXC/STØ. The operators were John, PA3DFT, PA3CWM, DJ9ZB and IK1HJS.

Spratly Islands. A group of Soviet operators, led by Romeo UB5JRR (and 3W3RR), activated the islands during April as 1SØXV, and one or two other callsigns. The Spratly operators were later active as 3W1PZ, 3W6PY, 3W9CZ and 3W1ØØHCM. Romeo postponed another trip to the Spratlys in order to activate Afghanistan (YAØRR during January 1991).

Yemen. 9K2CS and several other operators from Kuwait operated from the newly proclaimed Yemeni Republic as 7O1AA, the first legitimate operation in many years. 9K2CS, the QSL manager for this operation, is now living in Saudi Arabia, but the logs are thought to still be in Kuwait. The new Yemeni Republic was the result of a merger between North and South Yemen (4W and 7O) on May 22, 1990. The ARRL officially deleted the two former DXCC countries of Yemen from the DXCC countries list and added the Yemeni Republic (a two-for-one swap). A second operation from Yemen during late July/early August by J28AA, F6EXV and F2VX, was signed 7O8AA.

Malawi. Operators in Malawi returned to the air after many years of silence. For some years, only Les 7Q7LS was allowed on the air, and he went QRT several years ago. It was great to hear numerous 7Q7 stations on the air again. It was especially nice to hear Ron 7Q7RM who signed ZD6RM back in the '50s when the country was called Nyasaland. Times change.

Mozambique. Lloyd and Iris, W6KG and W6QL respectively, did it again and obtained permission to operate. They signed C9QL for several weeks. There had been no legitimate activity since the two-days-per-month activity by C9MKT several years ago.

Malpelo Island. A group of operators from Colombia once again operated from this rock with the callsign HKØTU. It was a very successful operation. QSL via HK3DDD.

Germany. Effective October 3, 1990, the German Democratic Republic (Y2–Y9) was deleted from the DXCC countries list after it was absorbed by the Federal Republic of Germany (DL, DK, etc.).

San Felix Islands. Beginning in late 1990, John CEØZAM began his operation from San Ambrosio Island as XQ/ØX, a very welcome operation.

Mount Athos. SV2RE/A and SV2UA/A removed Mount Athos from a large number of need lists. They were there to train Monk Apollo SV2ASP/A.

DXCC Activities. During 1990, the ARRL received several applications for separate country status. Other applications were processed by the DXAC and Awards Committee.

Walvis Bay. (ZS9) became a new DXCC country. Grosse-Ile (CIØGI) and the Puyallup Tribe of Indians (K7SS/PTI) were not approved for separate country status.

[Editor's Note: According to Terry Robinson VK3DWZ, Mr. Barry Wilton of the Victorian Division of the Wireless Institute of Victoria informed him that a QSL bureau for incoming cards no longer exists in the State of Victoria, Australia. Please do not send any cards to VK3 via the bureau.

Next, Douglas A. Donley, KG4 QSL bureau manager, says that QSLs will no longer be forwarded to people no longer residing in Guantanamo Bay. This is because people do not keep their addresses updated at the bureau. For more information, including a list of callsigns you can currently QSL via the bureau, send an SASE to Doug Donley KB4DD, Box 692, F.P.O., New York NY 09593-0055. Remember, only KG 2X2 calls are in Guantanamo Bay.] 73

Continued from page 96

worked great. I finally made a "real" vertical dipole out of a 19" piece of a mobile whip and copper tubing. It hung off of the curtain rod in our living room for over a year. I used the rest of the coat hanger (from the original vertical dipole) to build a basic quarter-wave ground plane. I tacked it up on the ceiling above my bedroom operating desk. Now I could work 2m from both rooms. Being on the second floor gave me enough height to make it into a local packet node, so I was on packet, too!

Determined to be a multiband operator (what good is a General Class license if you can't gloat to your Technician friends about all the great DX on 20 meters?), my antenna construction went into high gear. I wrapped the entire apartment in a twisting longwire so I could work 80m during Field Day. My wife put up with that for the duration of the contest, and I made a few 80m QSOs, but it was impractical for permanent installation.

I wrapped a multiband folded dipole around the bedroom ceiling. It was made entirely out of 300 ohm twin-lead. . . and it didn't work.

I spent all afternoon wrapping wire around an 8-foot pole, contructing my own helically-wound vertical. I wrapped about 130 feet of wire and attached 12" of whip to the top. Unfortunately, living on the second floor didn't make for the best grounding system. I cut counterpoise wires for every band and wrapped them around the base of the room. (As far as I know, the counterpoise wires are still hiding under the rug in that bedroom. It was too much of a hassle to dig them up when we moved, so I just left them.) Reception was pretty good, but I couldn't touch anything that even looked like metal without receiving a jolt that sent my heart into overdrive.

I finally decided that a loop was the way to go. I wrapped the room with a horizontal loop, fed it into my antenna tuner, and fired up. The antenna loaded fine. So did the TV, the telephone, the microwave, the stereo, the toaster oven, the blender, and the landlord's cat. I think maybe the ground controllers at the New Haven airport also had a few unkind words.

Still holding out for a loop, I strung a 10m, full-wave loop vertically around the bedroom window. With a jumper wire at the top, it also gave me a dipole on 20. I fed it with 400 ohm ladder line into my tuner. 10 meters. . . . no problem. 15m. . . Hey, I just worked four countries in Western Europe, and that's a Venezuelan calling me! This is great! 20m. . . "You're a little weak, old man, but I copy 100%." I'll accept that. 40m. . . SWR a bit high, but 5 and 9 reports all over the Eastern Seaboard.

That little loop stayed up for the rest of our time in that apartment. It caused terrible TVI on any band but 10m, so I had to self-monitor my operating times so as not to bother the neighbors. . . or the landlord. I worked close to one hundred countries on that indoor loop, including a few semi-rare ones pulled out of pile-ups. Even in the middle of a busy pile-up, I would always mention the indoor loop, and the DX amateurs would always stop the "5 and 9, QRZ" stream to ask a question about it or compliment my determination. A few of them even mentioned it on their QSL cards.

Now that we live in the country, I finally have a few normal dipoles strung up in the trees at a respectable height (though it cost me about 2,000 mosquito bites to get them up). I get a pretty good signal out on every band except 80m and 160m. . . and I do OK on 80m if the wind is right, if there's ice on the antenna, and if I'm careful with the antenna tuner. I can work Europe, Asia, South America and Africa any time the band is open. I'm not a "Big Gun" on any band, but if I hear it—and there's not an incredible pile-up—I can work it. I have my own radio room, so my wife doesn't have to put up with a wall of wires in the bedroom anymore.

I've been thinking about stringing up a LONG longwire—like a couple a' thousand feet—now that the warm weather is here. We've got the land, and I could spend all summer experimenting, adding a few hundred feet every weekend, but it's hard to get motivated when you're already doing fine with what you've got up.

I miss my indoor loop. 73

Some Weird Antennas I Have Known

Ah spring. . .when a young ham's fancy turns to antennas. You folks in southern climes have no idea what it feels like to live through a long, cold winter—watching the ice build up and strain your antennas, knowing that it will be several months before you can repair any damage. When the mercury starts climbing again, the ice on the lakes is all but gone, and the only snow left is the stuff that lingers in the shadows under the pine trees, we in the North can't wait to get out the ladder, slingshot, climbing belt, bow and arrow, and fishing line, and start stringing copper wire. The local hardware store quickly runs out of aluminum tubing, as the sweet sound of hacksaw blades cutting into metal can be heard.

As the spring antenna bug bites once again, I got to thinking of all of the antennas I have tried. We tend to associate the passage of time with certain things—popular songs, political events, the birth of children. I guess a ham marks the passage of time with the different antennas he has used.

The first time I put my own callsign out on the air, I was operating an HW-16 into a 15m dipole. That in itself wasn't so unusual. . .until you got a look at the dipole! It was made out of a spool of solid 24 gauge wire, bought at Radio Shack for about $1.49. Its insulation was bright red. It was fed with about 6 feet of RG-58 coax, and it was about three feet off the ground. It came straight out of my first floor bedroom window and was tied off to a fencepost on one leg, and to the branch of a bush on the other. I ran in and out of the house, trimming one-quarter inches, until I hacked off too much. Then, of course, I started adding pieces until I got a respectable SWR. My mother let me keep that antenna up for quite a while, bless her. My dad had to duck under it to mow the lawn. I didn't work any DX with that antenna, but I did work as far away as Texas. I was ecstatic!

A year or so later, my dad got his ticket. You have to understand something about the men in my family—we don't do anything halfway, especially when it involves gadgets, gizmos and anything that requires electricity to operate. Just ask my mom, my wife, or any of my sisters-in-law. The Cassidy boys just can't resist anything with a panel meter or an LCD on it. Needless to say, my dad quickly took to amateur radio.

One of the bedrooms became the radio room. An HW-101 and all of the matching accessories took their places on a custom-built desk. Upon the swift and inevitable upgrade to General Class, the various dipoles strung at the proper height off the peak of the roof were joined by a rooftop tripod tower and a triband beam. After a while, a complete Kenwood station replaced the homemade Heathkit stuff. It was a high school ham's dream: A beautiful, state-of-the-art station. How many members of my high school radio club could even compare their stations to this monument to global communications? And. . .it hadn't cost me a dime. Dear ol' Dad had provided everything. All I had to do was sit down and power up.

Wrong!

I never got closer than the kitchen to that dream station. Dad chased counties. He chased DX. He chased me right out of the operator's chair! Oh, sure, I snuck in a few QSOs after school, before he got home from work, but Dad took the unbelievably short-sighted attitude that he should actually be able to use all the stuff he bought, built and paid for.

During and after college, I was more concerned with partying (during) and paying bills (after) than amateur radio. It wasn't until after I was married that I was re-bitten by the radio bug. It's then that my antenna building became an obsession.

Dad's old HW-101 was still sitting around, so a rig was no problem. Putting up an antenna was a definite problem. We were living in a one-bedroom, second floor apartment in Connecticut. The first floor of the building was a busy florist/garden center, with a parking lot all around. All of our windows looked out over a busy street, so hanging a wire out the window was out of the question. At this point, my antennas started becoming weird.

First, I wrapped dipoles around the bedroom. That was OK on 10m during the peak of the sunspot cycle, but I wasn't getting out on any other band. Next, I tacked up a random length of very thin wire outside the bedroom window, along the front of the building. Aha! An outside antenna. . .and the landlord couldn't even see it. With my wife holding onto my legs so I wouldn't fall out of the window, I stretched every inch I could out of that wire. I ran back to the rig, fired up the HW-101, and started turning knobs on the antenna tuner. I got a beautifully flat SWR on 10m, but couldn't get any other band to tune up.

Working the local 2m repeaters was easy, even with 5 watts and an HT. I threw together a twin-lead J-pole, which worked but the SWR was too high. I taped a horizontal dipole to the window. Being on the second floor and close to several repeaters, it worked OK but looked kinda' strange. I finally decided that a vertical dipole was the answer. The first one used a piece of coat hanger for the top. The bottom half was a cardboard tube wrapped in tinfoil. It looked like something out of a 1950s science fiction movie, but it

First Two Weeks Best

April ought to provide some excellent DX for your logs. However, looking at the table, you can see that the first couple of weeks will be better than the last couple of weeks. Overall, there will be good and fair days intermixed in a generally poor outlook for each week.

April has traditionally been a good month for propagation on the HF bands. Once again, you will find the 20 through 10 meter bands open from shortly after dawn to shortly after dusk on many days of the month.

Last month we talked a bit about using the charts with WWV announcements to plan your DX efforts. Here's the way I work them: First, I look on the daily chart for those days marked "Good," and verify the forecast by monitoring WWV at 18 minutes after any hour for trends in conditions.

Second, I use the band-time-direction chart to find the most likely times that the HF bands will be open to a specific area of the world. As you can see, some areas are open on some bands and not others, and during a specific time. I choose the band most likely to be open in an area, and listen slightly before, during, and after the times indicated. Sometimes a higher frequency band will open up sooner than expected.

If you like the WARC bands, as I do, then look at the chart for 15 meter conditions and expect similar conditions on 17 meters. Sometimes the 10 meter band will be a better indicator of conditions on 12 meters, but also check 15 meters to see what's coming through. Thirty meters is an evening and early morning band for DX, and a short-skip band during the daylight hours.

In April, my best guess is that between the 20th and 25th, you might do better to take up another hobby temporarily, as the bands should be extremely poor. . .but there's always a chance that the forecast will be wrong, so check the bands anyway! See you next month, and happy DXing. 73

LETTERS

From the Hamshack

Joseph W. Bento N6DGY, N. Chicago IL Do things never change? Or should I put it, does the ARRL never learn from mistakes? I recently picked up a 20-year *73* collection (1960–80) and have been enjoying your old editorials. Old doom and gloom Wayne actually knows what he is talking about. The vast majority of your predictions from the '60s are a reality today. You said 220, use it or lose it in the '60s. The ARRL's incentive licensing scandal. Thought I'd let you know how right you've been all these years.

It is fun to read those old editorials. On the doom parts I wish I'd been wrong . . . . Wayne

Marv KB9KYV Several months ago, after receiving my Novice license, I subscribed to *73*. I find it to be quite interesting and informative, especially your editorials on the state of the ARRL and the ham bands, electric blanket nightmares, the electromagnetic/cancer connection, microwaved brain cells, ad infinitum. I'm feel that I'm getting a perspective on ham radio that I would not get in another publication. I am a computer teacher, and can certainly see the value of including radio theory in the school curriculum. As for project building, I do like to experiment when I find the time, but keep in mind that readers such as myself may not have the level of expertise that the hams who are writing the articles have.

Noted. By the way, "time" is a rationalization. You have the time to do what's important to you. It's not time, it's priorities. We all have the same 168 hours a week. . . . Wayne

Name withheld, ARRL employee "I get tired of all the lids complaining on packet, SSB, CW, etc., about 'those idiots in Newington.' If they put half the effort into at least writing to their directors instead of bitching over the air, they'd probably be much happier. You try to solve problems, the world will be a better place. Keep up the good work and keep on bashing the lazy members."

W. Richard G. Duane, Jr. WB2VAT, Long Valley NJ I was amused by what your staff did to Dave's (W5UN) article, "Two Meter EME Primer" in the March issue. On page 52, bottom of column 2, the word "libration" (the oscillation of the moon's face as seen from earth) was changed to "libation" (drinking)!

I agree that libration effects are short-term. However, I do not agree that libation effects are very short-term! I enjoyed the article all the more for the laugh it gave me unexpectedly in the middle of a very informative and interesting piece.

If only all our mistakes were so entertaining! . . . Linda KA1UKM

Walter Lindley NL7VM After all your nagging I have finally upgraded from Technician to Advanced. It seems that everyone who talks about code claims it is either easy or nearly impossible to learn. Nonsense; code is tough to learn, but with some practice it *will* come. I think a codeless license is great because technically-oriented people (as opposed to code-oriented people) are needed in this hobby. Let's all welcome any new people attracted to ham radio through the no-code license.

Malcolm G. Bowen VE6MGB, Ft. McMurray, Alberta I just finished reading "Random Output" in the January 1991 issue, and I would like to shake your hand!! I agree with you wholeheartedly.

In November 1989 I became interested in amateur radio. I approached a member of the local ham club, and he was very helpful. I purchased a used FT-101 at a garage sale from a ham operator and it turned out he became a good friend. A month or two later, I joined the ham club. I was informed that night classes would be starting soon.

I turned up the first night along with 12 other people. The second week, only 10 turned up; the following week, six came, and in the last 10 weeks of the 18-week course, only two of us showed up. Myself and the other participant appreciated both amateur operators teaching this course, and expressed our thanks. I took my exam and passed, the other person didn't try the exam.

Now this is the part that burns me, and I have told all the club members so!! At a general meeting at the end of summer, 18 people turned up, and we talked about everything. But not one word about myself and the other gentleman sticking out the night courses through winter at −25 degrees, or even that I had passed my exam. I waited until the meeting ended, and there was nothing said, and I swore I would never attend another club meeting. Can you imagine how a new member would feel in that kind of atmosphere? I thoroughly enjoyed your article and found myself agreeing with everything you wrote. Thank you for your patience and the opportunity to voice my opinion.

Thanks for sharing your experience. Unfortunately, we've received dozens of similar letters. I'm glad you told your club how you feel. Maybe it will help (but I doubt it).

What struck me most about your letter was the fact that your licensing class took 18 weeks. 18 weeks!!!??? No wonder you had so many dropouts! If it's run correctly, it shouldn't take more than 8 weeks (or is there something peculiar about the Canadian license that requies 1/3 of a year to learn?). . . . David N1GPH

Fred Smith K3MOA, York PA After following the code vs no-code debate for what seems like an eternity, I am pleased to see that the FCC finally made the most logical and rational decision on the matter. I am one of the many unfortunate ones who had to suffer through learning code to obtain my license, but I would not wish that "rite of initiation" on my worst enemy. . . . Though the FCC has made its decision, I expect that the debate will go on forever or until the code fanatics die off. Max Planck summed it all up when he wrote: "A new scientific truth does not triumph by convincing its opponents and making them see the light, but rather because its opponents eventually die and a new generation grows up that is familiar with it."

I hope that we are able to spawn that new generation so that amateur radio doesn't die out with the code fanatics.

Nice quote. Max was too science-oriented. The quote holds water even when you take the word "scientific" out of it. . . . Wayne

Joe Plitnick KA1WPD, S. Meriden CT While attending the 31st Tropical Hamboree Amateur Radio/Computer Show in Miami, Florida, a situation developed that I think is quite amusing. While visiting your exhibition booth I was given a copy of *73* at no charge. I really appreciated it and I signed up for a subscription. While visiting other displays I came up to . . . *[another ham magazine.]* It was kind of strange to see that they were charging one dollar for their current issue. I commented to the staff working the display that I received a free copy of *73*. The reply was, "Well, that's all it's worth." Amazing. I have since decided to stop purchasing this magazine and sister publications. I enjoy your *whole* magazine. Thanks again for the free issue. Keep up the good work.

Hi, Joe—I remember meeting you in Miami. This kind of adolescent name-calling has been going on for years among the major ham magazines. Kinda' stupid, isn't it? . . . David N1GPH

E.J. Kidd, III, WD4ILS, Naples CA Over the years, I have been a retail purchaser and subscriber to your magazine. I have never agreed so completely with your observations on the general wrong-headedness of many of our ham brethren.

Every leisure activity which can be divided into groups seems to suffer from periodic infusions of petty authoritarians bent upon enforcing the "rules." Small Minds will find a way to smite the assembled faithful with the Rules, and attempt to convince them that some particular loss of individual freedoms is Good For Them.

There is a scatological Southernism that, to paraphrase it, attributes the desire to enforce discipline upon smaller groups to a void in one's sex life. So, for years I have assumed that old men with callsigns from the first and second districts, holding ARRL posts and Extra tickets, tended to be petty authoritarians and general noxious busybodies because the lack of ultraviolet rays in the Northeastern winters attenuated their libidos. What a revelation, if your hypothesis is correct! Facing Newington and genuflecting five times daily doesn't make one an old fart: CW makes one an old fart!

Having read much on EMF and cancer, becoming interested due to your editorials, I often chastise emergency services workers and hams for using those cute microphone/rubber duck antenna combinations which they gleefully pin and clip to their lapels and epaulets. Two meter energy radiated 8" from one's eyes is probably not a great idea; 70cm radiation from an antenna closer to the brain than the elbow can be shown, according to some tests in the '60s and '70s, to be hazardous to one's eyesight. But *what* does the emission of 800 MHz cellular telephone signals from all those Nokia and Motorola units up right next to the ear do for the brain? Can we expect a Yuppie Brain Disorder in the 21st century?

The current ratio of Agreement/Disagreement between the NSD editorials and my own views is running about 70:30 in the last five years. I find this an alarming trend, inasmuch as I celebrated my 40th lap around the sun last year. Instead of a young, wild-eyed Cracker who disagreed with you about 70% of the time and burned the tires off my mobile, I now look like Wilfred Brimley, find more wisdom in the counsel of those with more experience, and am trying to cut my own personal dependence on foreign oil by a few barrels a week. Not quite ready for Old Farthood, I did reregister as an Independent this year.

It's interesting that your agreement factor has risen with wisdom—why, it's almost enough to make a person think! Perhaps it's time to dig back through old rags and recheck old editorials and see how well they've withstood the test of time—vs your take at the time. Please advise. . . . Wayne

Michael A. Sciomacco N3HUX, Pittsburgh PA I've been a *73* subscriber for a year, and I've gone from nothing to General in 13 months. I am using your advice about bringing ham radio to my students at the Greenway Middle School Teacher's Center. This past summer I instructed a Novice class sponsored by the New Futures extended day program, and elmered a new Novice, Brian KA3WXH. I am currently starting a new Novice/Tech class. I am also awaiting the installation of our Cushcraft vertical to get on 10 meters.

During a recent demo at Greenway, I had a real life emergency that required me to contact 911 and a child's parent through 2 meter autopatch. A student had fallen down a hill and cut her foot open on a broken bottle. The students were able to view firsthand how I was able to lend a hand.

I also occasionally take check-ins for a local swap and shop repeater net. This gives me great personal satisfaction, and I feel all hams should contribute to our hobby in whatever capacity that they can, and not look down their noses at the young. I.E. "Lids"! (We have a local club that screens their applicants and will not admit young hams. What a crock!)

Thanks for your inspiration. I am becoming an "unreasonable" person.

Ervin L. Sly, Nipomo CA Have been reading your editorials for a long, long time, and even though I don't always agree with everything you say, I enjoy them. Have always been very envious of all the things that you do, *but* it takes money to do it with. I "just ain't never had none of that stuff to do all those things," and your March editorial finally told me why. Just don't have the I.Q. for it!

I have had Advanced ticket for 51 years. I just retired a few years back, and I had to spend what little I made on my family, and not extras, like the hobby or traveling. Guess it's too late now to get smart!

I hope the no-code ticket brings in lots of new hams.

NEVER SAY DIE

Wayne Green W2NSD/1

FCC Screws Up!

The FCC has tried to kill an ant with a sledgehammer. Actually, though I'm dumping on the FCC, it's mainly our own fault that this nonsense happened.

By now, unless you've been living in a black hole, you know that a ham who was protesting our attacking Iraq sent a message through a packet system asking people at the other end to make a 900-number call. Since there's a charge for 900 calls, an FCC engineer, alerted to this terrible crime, started issuing fines right and left, and in general dumping on a number of hams whose packet stations relayed the message. Talk about overreaction!

Yes, it was in bad political taste to question President Bush's decision to clobber Iraq. And yes, we're not supposed to use amateur radio to generate money lor causes. But the crime here was more on the order of a yellow-line violation than a hanging offense. We've been used to hearing worse attempts at using amateur radio to sell things than that. . . like those endless solicitations for subscriptions to a ham magazine (not mine, darn it) via supposed information bulletins.

For years we've bragged about how great we are at being self-regulating and self-policing. Then, whenever an Extra Class CW-crazed ham goes berserk on the air, the first thing we do is go whining to the FCC, demanding they put the SOB off the air. Do we do anything about It ourselves? You bet we do! We sit there, wringing our hands and complaining for a while before we telephone the FCC.

The FCC engineers, delighted to find an incident where they are on the moral high ground for a change, have leaped Into this mess with an atom bomb to pacify a flea. FCC, get the heck off our backs and stop being dumb. Yes, we know we're not supposed to handle messages that involve making money for someone. That doesn't mean that some ham somewhere isn't going to do it. And it doesn't mean that you have to close down the hobby just because we have a few idiots.

A message going through a packet system, no matter how illegal, isn't going to do a lot of harm. Let's put this baloney into perspective. Most ops don't even bother to read the traffic being relayed through their stations. Like a repeater, they're providing a service.

So what should we do? Is it time to start trying to write new regulations that will allow us to cope with this dire emergency? Or is it time to stop being silly? I vote for the latter. We need fewer regulations and less unneeded harassment from the FCC.

If we are such wimps that we can't handle the creeps who've been screwing up 20m with unwanted broadcasting, officious net jamming and pile-ups on DX, then we deserve all the miseries we have. Yes, of course the ARRL could do something about it. I happen to think they not only should, but that it's their responsibility to keep our bands clean. And I think ill of you for being a member and being too afraid to tell them what you think. . . and for endlessly voting for directors who refuse to do anything.

Now tell me how you don't agree with everything I write. What part don't you agree with?

When I Grow Up . . . ?

Yes, I know, most of us are in our 60s and it's difficult to remember when we were kids and we'd wonder what we might do when we grew up. But suppose you get into a position where you are going to be a mentor to a youngster—what kind of advice would you give?

It's difficult to look back from retirement age and assess what we've done with our lives. It can be even more difficult when we think about what we might have done.

If you were to be in a position to mentor teenagers, what guidance could you give them? Could you point to your own success and the impact you've made on the world as an example of what's possible for them?

What did you want to be when you grew up? Did you make it? Or have you gone on way beyond anything you imagined? Or have you fallen far short of your dreams?

If you're short, is it loo fate to try again?

Amateur radio can be the key which unlocks a lifetime of excitement and growth. When my friend Alfie and I were given a box of old radio parts one Sunday in church, Alfie had little interest in the junk, so I took it home. The "angel" who gave that box of old parts to two kids that day changed one of their lives.

I joke that one of the great tragedies of my life was when the *Popular Mechanics* radio I built with those parts worked. It was a turning point. Perhaps this is one reason why I'm so anxious to touch as many kids' lives as possible with the magic of radio.

How can a teenager understand enough about how life works to set any realistic goals? Perhaps, as a mentor, we who've been through it can help explain about the attractiveness of the pitfalls. How can we get across the Importance and the fun of learning when kids are up to here in lousy teachers, menacing peers, impossible parents, and threats of war and destruction?

How can we explain in terms they can understand that there are an infinite number of ways in which the world will try to head them off? That Darwinian survival of the fittest really does work, even on a personal level?

We have a wide variety of drugs for the body and the mind, all geared toward keeping them from success. There's alcohol, which their parents, television and the movies try to convince them is cool. Smoking doesn't have quite the cachet it did a few years ago, but with the uneducated it's still cool. Junk food and overeating are pushed at us from every side.

How about junk food for the mind such as ball games (of all kinds), 95% of the television fare, most movies, comic books and most newspapers? There are a lot of junk books too. . . and junk music.

How easy it is to get involved with shortcuts where you substitute a belief for the more difficult work of learning and understanding. In this category I'd put politics and every religion except yours. I've put together a whole long list of very worthy causes, any of which can derail your progress through life.

I'm as aware as you of the dangers to Gaia. I keep up on the redwood loss, the rain forest destruction, the whales, dolphins and baby seal losses, the greenhouse effect, and even that poor little snail darter that sidetracked a billion dollar dam project.

Yes, I see how the world is coming apart. I know about the race problems all around the world, the tribal enmities everywhere. The wars in Iraq, Timor, Chad, Somalia, Ethiopia, the Philippines, Central America, New Guinea. The killing of students In China and Burma. And many of these are personal with me because I've visited these places and have friends in them.

My ham friends in Czechoslovakia and Poland, whom I visited just last year, are deeply Involved on a daily basis with the turmoil in these countries, so what's happening in Eastern Europe is more than a passing news item for me. I've been to Wenceslaus Square in Prague. I've seen the hundreds of candles burning for those killed in fighting communism. I've sat and talked, ham to ham, with the people who are living through this terrible period.

Amateur radio has a whole world to offer, if only you can get this message across to the youngsters around you. It isn't easy. They're probably much more interested in Nintendo and collecting bubble-gum cards.

How much do you know about amateur radio? How much have you taken advantage of this cornucopia of wonder to expand your own horizons? How can you communicate the wonders amateur radio offers if you've never yourself even tried them?

Can you get up In front of your ham club and explain how RTTY works? Are you comfortable with bauds and digital communications? How'd you like to tackle spread spectrum for the club? How about writing an article on it for *73*? Or even a book? Why not? I've written many articles and books on RTTY, so why not you? Oh, *I'm* different in some way? How? Why?

Yes, of course I'm different. We're all different. But we all have to accept responsibility for the way we are—and change it if we're not satisfied.

When I was growing up I hadn't a clue as to what I wanted to do. Which was just as well, since most of the things I've done couldn't have been predicted. How could I imagine as a high school student getting involved with amateur radio that this would lead me In a few years to being an electronics technician on a submarine in the middle of a war?

Television was just barely starting when I was in high school so how could I guess that I'd become a TV director a year after getting out of college? Or that I'd become a professional psychologist a year later? I wouldn't have believed it! And then a couple years later I was the partner in a million dollar loudspeaker manufacturing business. Things like this are completely unpredictable, aren't they?

Or are they really? Yet wasn't I following some general goals all along? Most of my life was determined when that box of radio parts was given to me in church that Sunday. Yet even then I was ready for it. Alfie had the same opportunity, but he wasn't able to take the next step. How about you? Are you missing opportunities the way Alfie did?

Through the magic of amateur radio I've sat and talked with a king in his

QRX . . .

EDITED BY LINDA RENEAU KA1UKM

New Rules Sought

The FCC has accepted a petition requesting that primary responsibility for the content ot all automatically retransmitted signals be placed on the originating station. The petition, authored by Tom Blackwell N5GAR of Dallas, Texas, was designated RM-7649. It calls for a modification of Part 97, adding to Section 97.205 a section (g).

The licensee of the repeating station, whether analog or digital, would hold only a secondary responsibility for the re-transmission. Basically, he would be held responsible only to the extent that it was humanly feasible for him to intercept and censor the violation. Conversely, the user breaking the rules of the Amateur Radio Service would be the one to suffer the most severe consequences of the violation.

Earlier, the ARRL had also submitted a proposal to the FCC on this matter, but it was turned down. Blackwell feels that his petition may be successful because it calls for some measure of shared responsibility. The ARRL proposal, he said, regarded the originator solely responsible for his message.

Last January, as reported in the April "QRX," a number of packet BBS operators were fined $300, and others were cited for allowing the re-transmission of an anti-war message urging users to call a 900 number. The message did not mention the $10 fee that would be charged to the caller's phone bill. The sysops of the packet BBS stations have responded to the allegations of impropriety, but the matter is still on hold. They don't know if they will be exonerated or penalized further.

Jim Dearras WA4ONG, one of the hams cited, says, "I believe it [RM-7649] will go a long way in taking care of the problem." He pointed out, however, that "primary" and "secondary" responsibilities ought to be better defined. He added, "I am also concerned that a lot of hams do not seem to understand what has really happened. They don't see the implication as going beyond the packet BBS systems having to screen messages. They don't realize that this can be applied to digipeaters and voice repeaters!"

N5GAR said that he wrote his rules change petition to include both analog and digital modes, so that separate regulations would not be necessary. From No. 597 of the *Westlink Report.*

Balloon Experiments

Look for a student balloon experiment which will be launched at 10:00 a.m. EDT on April 27 from the U.S. Naval Academy in Annapolis, Maryland. The balloon will take a 2m FM transmitter (144.34 MHz) up to about 80,000 feet. Telemetry will consist of a CW ID

Photo A. WB4APR atop the 40-foot tracking dish at the U.S. Naval Academy.

(W3ADO Balloon) and a series of tones indicating inside/outside temperature and altitude. Anyone within 400 miles may hear the signal. They'll be using a 40-foot diameter dish to track the payload as it drifts along. See Photo A. Contact Bob Bruninga WB4APR at the Aerospace Dept., U.S. Naval Academy, Annapolis MD 21402, or call (301) 267-4380.

Spring balloon launch schedule:

April 13 at 7:30 a.m. CDT, Franklin IN (WB9IHS). Live camera ATV on 439.25 MHz. 2m FM on 144.34 MHz. 10m CW on 28.321 MHZ. HF nets on 3.871 and 28.331 MHz. Contact Chuck Crist WB9IHS at 6455 S. Madison Ave., Indianapolis IN.

Mid-April, Hillsboro WI (WB9SBD). Two meter repeater. Input of 144.48 MHz and output on 147.48 MHz. HF net on 7.155 MHz. Contact Joe WB9SBD, Rt.1 Box 235A, Hillsboro WI 54634.

May 4 at 9:30 a.m. MDT, Denver CO (AAØP). Live camera ATV on 426.25 MHz. 2m FM with voice telemetry on 144.34 MHz. 10m CW on 28.8 MHz. HF nets on 7.232 and 28.332 MHz. Sponsored by Edge of Space Sciences, Inc. Contact Jack Crabtree AAØP at 4327 Bellewood Dr., Littleton CO 80123.

May 11 at 9:00 a.m. CDT, Houston TX (WB5HLZ). Live camera ATV on 439.25 MHz. 2m FM packet and CW telemetry on 147.435 MHz. 10m CW on 28.322 MHz (K7IRK). HF nets on 7.155 and 28.332 MHz. Contact Burns Cleland WB5HLZ at 5106 Elm St., Houston TX 77081.

May 18 (morning), Whiteville NC (KC4WDW). Students at Southern Community College plan to launch a TV camera into space. See the ATV column in this issue for details.

June 15 (morning), Mojave Desert (W6BHZ). Student members of the Society of Women Engineers (SWE) at Cal Poly University in San Luis Obispo, California, plan to fly an atmospheric sampling experiment up to 80,000 feet on a large balloon. Telemetry downlink will be on 2m FM with live camera ATV on 434 MHz. Write to the Cal Poly Amateur Radio Club, UU Box 53, Cal Poly University, San Luis Obispo CA 93407 (attn: David Fichou KB6OEN).

SWLing for News

Over the past few months, the sale of shortwave receivers has gone up 500%. Every country is selective about the news it broadcasts, and every country broadcasts some amount of propaganda, or material intentionally slanted to some degree, for its purposes. Many people have turned to shortwave to get the latest news faster, and also to compare reports of the same events.

Israel at 9435 (also at 7465 and 11605) kHz gives you right up-to-the-minute reports at 7, 8, 9, and 11 p.m. EDT. The BBC in London reports news about world events that you may not hear in the U.S.A. Listen on 5975, 6175, 7325, and 9915 kHz. A station in Dubai seems relatively unbiased; listen for it at 11 a.m. EDT on 11795, 13675, 15320, 15400, 21605, and 21675; and at 10:30 p.m. on 13675, 15400, and 15435 kHz. At 7 p.m. EDT, you can hear Moscow on 15205 or 15330; or at 8:30 p.m. on 7400, 9750, 15180, and 1770 kHz. Budapest, Hungary, is on 9835 (no time given) kHz. Iraq has been heard on 11990 or 9022 kHz in various languages. Kuwait was on 11990 (using a Saudi station?). Syria tells their side on 9950 and 12085 between 3:05 and 5:10 p.m. These are only a few of the many, many broadcasts on the air. *Frequencies listed are from* B-N-T Bulletin, *Vol. 19, Issue 3.*

Scanner Law Inquiry

Early this year, the ARRL submitted a request to the FCC, now known as Docket 91-36, that it pre-empt licensed amateurs from local scanner laws. State and local laws may prohibit the possession of ham radios—even by hams—if these radios also cover po-

QRX . . .

Tabitha Carty N1IEQ is a member of the NSRA home repeater on 146.88.

lice or other public safety frequencies deemed illegal to listen to.

Laws vary from state to state. New Jersey requires police-issued shortwave radio permits; Kentucky law authorizes officials to seize and destroy any radio equipment capable of receiving police signals; a Michigan statute exempts licensed amateurs—except for Novices and Technicians!

The ARRL pointed out that most 2m transceivers receive a range of frequencies between 139–174 MHz, which includes many public safety frequencies. The League believes that regulation is solely a federal function, and should not be left to the states. However, three of the five FCC commissioners studying the proposal have already said that they don't want to pre-empt local laws; instead, they want to know how *existing* ham transceivers and scanners could be modified to remove any capability to receive public safety radio frequencies. Under this proposal, new scanners and ham gear would have to be designed to *skip* public safety bands!

The FCC is also trying to figure out if there should be an exemption for General Mobile Radio Service licensees and equipment. Many hams, agencies, and groups use the 460 MHz GMRS, one of the Part 95 personal radio services. Then there is the Association of North American Radio Clubs, representing unlicensed shortwave listeners. It has asked for a general pre-emption for licensees and non-licensees alike.

The idea that owners of existing equipment might be required by the FCC to delete frequencies, and that newly manufactured receivers would be designed without the ability to pick up police, fire, and medical communications, is an unprecedented idea. *TNX* W5YI Report, *Vol. 13, Issue #5.*

What Counts

Tabitha Carty N1IEQ, a 13-year-old General class licensee, has been a ham for almost a year. She and her father, Joe KA1EXZ, do a lot of ATV demos at radio clubs and schools. The last demo was for an audio/video class at the Danvers High School. She is also a member of the NSRA home repeater on 146.88.

Tabitha is a student at Middle School West in Salem, Massachusetts. She holds an A-B average, and is being considered for the National Honor Society.

"I'm jealous of the kids with ham radio clubs in their schools," she writes. "Kids at my school think I'm nuts (hi, hi). I like ATV and ham radio, and that's all that counts." *TNX Tabitha N1IEQ, for responding to the request for information.*

Drake is Back!

R.L. Drake is back with a new shortwave receiver—the R8. From the early '50s to the early '80s, Drake offered a wide array of shortwave and ham equipment. For about the past eight years, it has concentrated its resources on its satellite receiver business.

The new shortwave receiver, called the R8, operates in the AM, LSB, USB, CW, RTTY, and narrowband FM modes, and covers from 100 kHz to 30 MHz. With an optional module, the R8 can also cover fire, police, public service broadcasts, and additional amateur bands in VHF (35–55 MHz and 108–174 MHz).

For more information, contact the R.L. Drake Company, P.O. Box 112, Miamisburg OH 45342.

Radio Video

"More Than Radios" highlights the importance of bringing others into the hobby. This 28-minute video was created and produced by Zman Productions, which is owned by Chuck KE7SA and Dixie N7OYY Zappala of Bothell, Washington. It was filmed in towns throughout Washington State.

"More Than Radios" video tapes are free, but there is only a limited number of them. For availability, contact ICOM America, Inc., 2380 116th Avenue N.E., Bellevue WA 98004. A tape must be ordered on ham club letterhead stationery. *TNX* Digital Digest, *Vol. 4, No. 1, and ICOM.*

Novice/Tech 80M Change

The Novice/Tech subband on 80 meters has been moved down to 3675–3725 kHz. The former privileges were from 3700–3750. If you're studying for a license, be sure to make this change in your books. If you have a frequency and mode allocations chart, you might want to note this change on it, too. *TNX* B-N-T Bulletin, *Vol. 19, Issue 3.*

Number One Ham

Ten-year-old James Catalano KC4SZT is the first of four Cub Scouts in Webelos Den 1 of Pack 1189 to pass his Novice exam. Now he is studying for his Technician ticket. He has been operating mostly 10 meters, and he has already confirmed DX QSOs with countries as far away as Australia.

Like many boys his age, he enjoys playing video games at home on TV. But he also enjoys the martial arts and playing the piano. He has recently earned his orange belt in Tae-Kwon-Do. *TNX Denis Catalano.*

James Catalano KC4SZT, a Cub Scout in Webelos Den 1 of Pack 1189, has his Novice ticket.

The Copperhead Keyer Paddle

The perfect touch!

by Charles D. Rakes KI5AZ

How many times have you wanted to try your hand at sending CW with an iambic keyer paddle, but didn't want to spend Mom's grocery money just to find out if it's really your cup of tea? Or maybe because you're just plain tired of trying to keep your mechanical monster adjusted? Or because you're still looking for that spring that took off like a ballistic missile? Whatever your reasons, you could consider building the "Copperhead Keyer," and enjoy the serenity of a nonmoving, nonmechanical, no-nonsense, electronic touch-activated keyer!

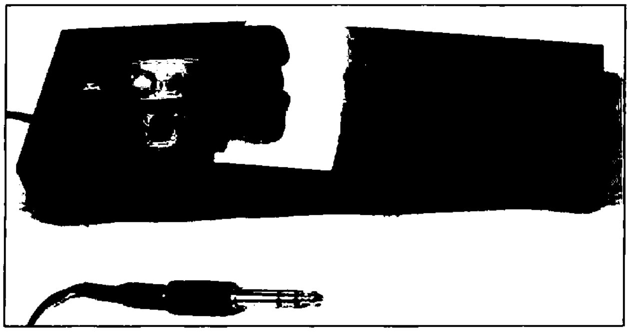

Photo A. The Copperhead Keyer—an ingenious alternative.

The Copperhead Keyer was especially designed for the home project builder who can take advantage of a few simple skills and fabricate a useful piece of equipment for a fraction of the cost of a similar commercial item. If you are a good parts scrounger—and what seasoned ham isn't?—you probably can build your own version for less than ten bucks. You can also order a kit (see the Parts List).

The paddles will operate with most commercial and home-constructed electronic keyer circuits using the Curtis chip, including the built-in versions in many current transceivers.

How the Keyer Works

Take a look at the keyer's schematic diagram in Figure 1, and you'll see just how easily electronics can replace a mechanical device. Also notice that an on/off switch isn't used or required because the standby current is so minuscule. The battery could survive in standby for its normal shelf life.

A single 4093 CMOS quad 2-input NAND Schmitt trigger IC and two 2N3904 transistors control and direct the circuit's electron flow. The two unused NAND gates are electrically stabilized by tethering their gates to circuit ground. The keyed output is fed through a mini or standard ¼-inch stereo phone plug to mate up with the majority of electronic keyers.

The "dit" (left) paddle is connected to the input of gate "A" through a 100k resistor, and back to battery positive through four series 10 megohm resistors. The very small current flow through the 40 meg resistor string holds the input high. In standby the gate's output, pin #3, is low. When the paddle is bridged, through your skin resistance, to circuit ground, the gate's output goes positive, turning Q1 on.

Q1's collector switches any positive load connected to the tip of the phone plug to ground, holding it there until the ground bridge is broken at the paddle. The "dah" paddle circuit operates in a like manner, with Q2 doing the output switching. The inputs of both gates are RF-bypassed with a 39 pF capacitor.

Bnilding Your Own Copperhead Keyer

The paddle's physical configuration can be just about anything you desire, or you can duplicate my model as shown in the figures. You can bread-board the circuit, or use perf-board. For a neat package, follow the PC board layout. If you do the breadboard method be sure to use an IC socket. No matter what scheme you follow, be sure to take special care in handling and installing the CMOS chip.

Woodchucking: See Figures 3 and 4. The keyer's base is shaped out of a hardwood block 3" x 8½" x 1¼", to match the drawings in Figure 2. A 2½" x 2¼" x 1" cavity is

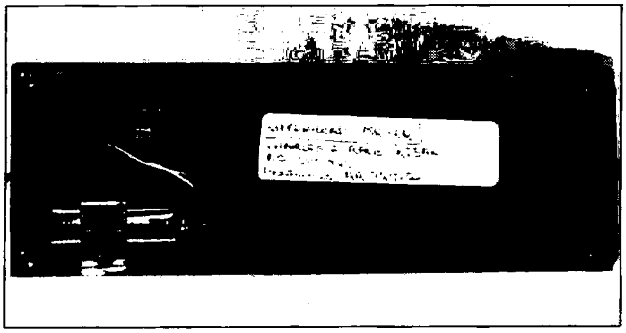

Photo B. The circuit is mounted in a compartment underneath the wooden housing.

Parts List for the Copperhead

B1	9 volt transistor battery
C1,C2	39 pF ceramic disc cap
C3	0.1 µF ceramic disc cap
IC-1	4093 quad 2-input NAND Schmitt trigger
Q1,Q2	2N3904 NPN transistors
R1,R2	100k, ¼ watt resistors
R3-R10	10 megohm resistors
R11,R12	4.7k resistors
Phone plug	stereo mini or standard, ¼-inch plug

Misc.: Hardwood material, circuit board material, battery snap, battery holder, nylon hardware, solder lugs, wire, solder, etc.

You can obtain a complete kit of parts, including a shaped base and spacer ready for stain or paint, paddles, hardware, circuit board, and all components postpaid for $27.95 from the author at Krystal Kits, PO Box 445, Bentonville AR 72712.

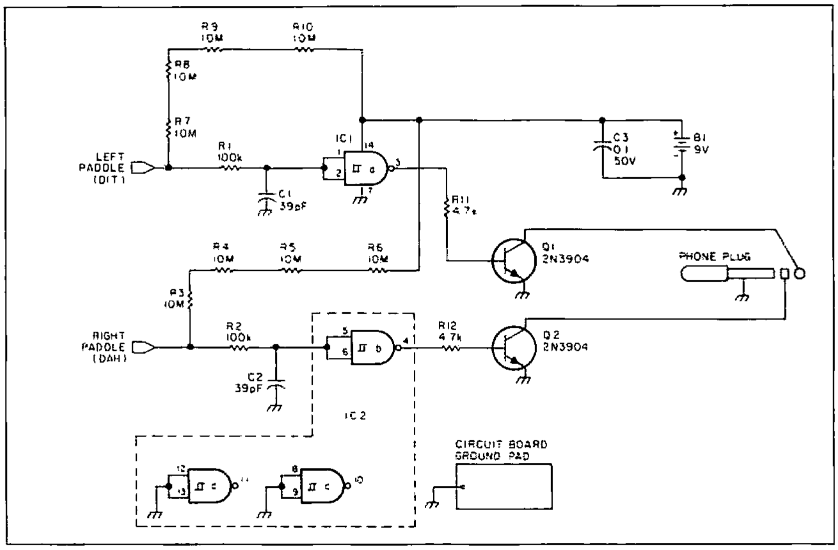

Figure 1. Schematic for the Copperhead Keyer circuit.

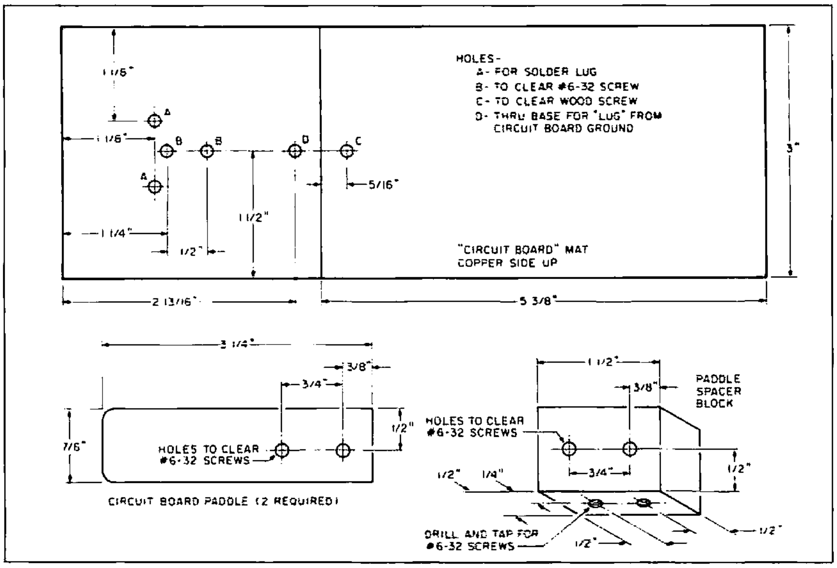

Figure 3. Plate dimensions.

carved from the base to hold the circuit board and battery.

A paddle spacer is cut to the dimensions, as shown in Figure 2, from the same hardwood material. The two paddles are cut from circuit board material to the size and shape shown in Figure 3. Two holes are drilled in each paddle to match up with the two holes in the spacer block, and the corners of one end of each of the paddles is rounded with a file or belt sander. The edges are smoothed with a fine grit sandpaper.

After the above is accomplished, you can drill the paddle mounting holes through the side of the spacer block, as shown, and then drill two holes in the bottom of the spacer. Thread each for a 6-32 metal screw. Drill four holes in the base, and mount the spacer board in place with two 5/8-inch 6-32 screws.

The grounding board, a section of circuit board 5⅜" x 3", is mounted to the keyer's base with glue and a single wood screw. A long solder lug extends from the wood screw through a hole in the base (see photo of completed keyer) to the cavity where it connects to circuit ground.

The paddles are mounted to the spacer with nylon 6-32 screws and nuts. A long solder lug on each paddle is secured by the nylon hardware and extends through the base connecting to the circuit as shown in Figure 1, the schematic.

Figure 4 shows the component side of the circuit board and parts placement. Mount the parts as shown and solder them in place. Then connect the paddles, grounding pad, battery snap, and output plug wires to the circuit board.

Mount the circuit board to the inside of the cavity with a ¼" plastic spacer and wood screw. The battery is kept in place with an L-bracket made from a spring steel, 9 volt battery holder, and is mounted to the edge of the cavity with a wood screw.

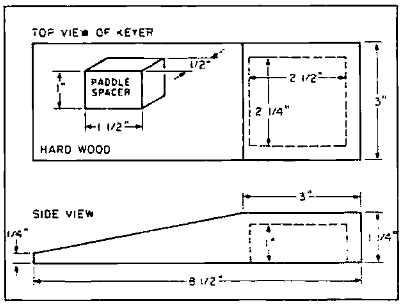

Figure 2. Dimensions for the wooden housing.

Checking Out the Keyer

With a battery in place, take a VOM in the RX-1 position and connect the positive lead (don't rely on red to mean positive, check it out) of the meter to the tip of the keyer's output plug and the meter's negative lead to the common sleeve on the plug. Position your wrist on the grounding pad and touch the "dit" (left) paddle. The meter should go from infinite resistance to near zero. To check the "dah" (right) paddle, first connect the positive meter lead to the ring on the phone plug. Next, with the negative still attached to the sleeve, touch the right paddle; the meter should drop to near zero ohms. If so, your copperhead keyer is ready for service.

Charles D. Rakes KI5AZ, P.O. Box 445, Bentonville AR 72712.

The Handy Inductance Bridge

For measuring small coils.

by J. Frank Brumbaugh KB4ZGC

Hams who home-brew antenna tuners, VFOs, QRP transmitters, and receivers are usually faced with determining the values of small inductances. While there are expensive digital and analog instruments available commercially, their cost and capabilities usually exceed the budget and actual needs of the average ham. Even most of the inductance measuring devices described in the ham literature seem overly complex, and often require hard-to-find component parts. The instrument described here is a simple, inexpensive but very useful gadget for quickly measuring the inductance of small coils.

Description

The circuit is illustrated in the figure. A Pierce crystal oscillator is isolated from the bridge circuit by an emitter follower which applies approximately 2 volts rms (root-mean-square amplitude) at the crystal frequency across the bridge.

The unknown inductance is connected in series with the bridge variable capacitor, which is then tuned to balance the bridge, as indicated on the center-zero microammeter. The inductance of the unknown is indicated on the calibrated dial.

This instrument, which operates at a frequency of 5 MHz, is capable of measuring from about 1 µH to 30 µH. This range encompases the vast majority of those small coils that need to be measured accurately.

Theory of Operation

The Pierce crystal oscillator, and the emitter follower, together comprise the generator that provides operating voltage to the bridge. The bridge is the heart of the instrument. L2 and C6 in series form the two fixed, known legs of the bridge.

The values of 22 µH and 47 pF were chosen to be series resonant at the 5 MHz crystal frequency. Because of the phase relationship between voltage and current in a series circuit, there is approximately 3.6 volts rms of RF at the junction of L2 and C6 when approximately 2.1 volts rms of RF is applied across the bridge, measured to ground. This allows greater voltage variation across the null detector formed by the center-zero meter and back-to-back diodes, which makes the null indication easier to determine accurately.

The back-to-back diodes, D1 and D2, are required both to rectify the RF voltage and to allow the center-zero meter needle to swing to both sides of center so an accurate null can be obtained. Although the diode conduction "knees" will appear at the center zero null, slightly broadening it, this does not adversely affect bridge accuracy.

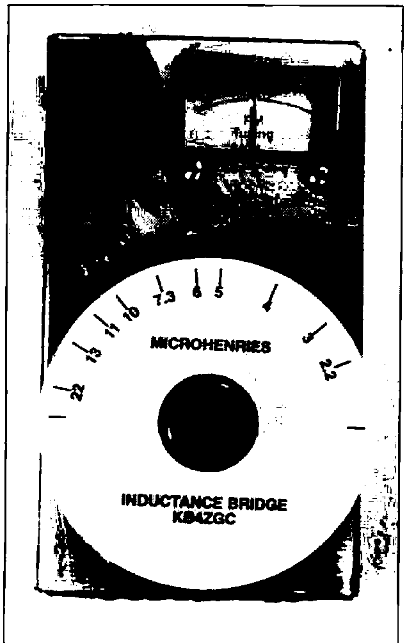

Photo A. The Inductance Bridge.

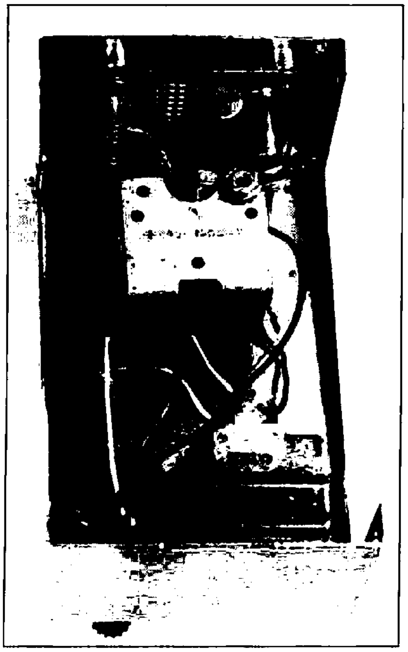

Photo B. Internal view of the bridge.

You can use crystals of other than 5 MHz, but if you do, you *must* change the values of both L2 and C6 so they are series resonant at the chosen crystal frequency.

Bridge tuning capacitor C7 is a nominal 365 pF variable capacitor removed from an ancient broadcast receiver. With this value capacitor and a bridge frequency of 5 MHz, inductances from about 1 µH to 30 µH can be measured accurately.

Using a smaller or larger capacitor and retaining the 5 MHz bridge frequency will shift the range over which inductances can be measured. Using a different frequency crystal (and changing the values of L2 and C6 appropriately) will also shift the range of measurement. However, regardless of the bridge frequency, the minimum capacitance of C7, plus stray circuit capacity, establishes the minimum measureable inductance.

Because the bridge frequency must be stable for accurate measurement of inductances, a crystal oscillator must be used. Any crystal oscillator circuit can be used—but the Pierce is the simplest and most foolproof. Remember, though, if you use a different crystal frequency, you may have to use different values of feedback capacitors C1 and C3.

This instrument is powered by a 9 volt battery to make it portable. You may use almost any DC voltage between about 6 and 15 volts. Using a 9 volt battery, total current drain is less than 15 mA.

An LED in a "free current" circuit is included as a power-on indicator. Because total operating current flows through the LED, it does not increase the load on the battery. Also, the LED will grow dimmer as the battery is depleted through use, alerting you to replace the battery.

The bridge is designed so that its tuning capacitor, C7, has its rotor plates grounded, simplifying construction and eliminating hand capacity from interfering with the accuracy of measurement.

Construction

The Inductance Bridge must be constructed in a shielded enclosure. An aluminum box, or an enclosure made from double sided PC-board material, may be used.

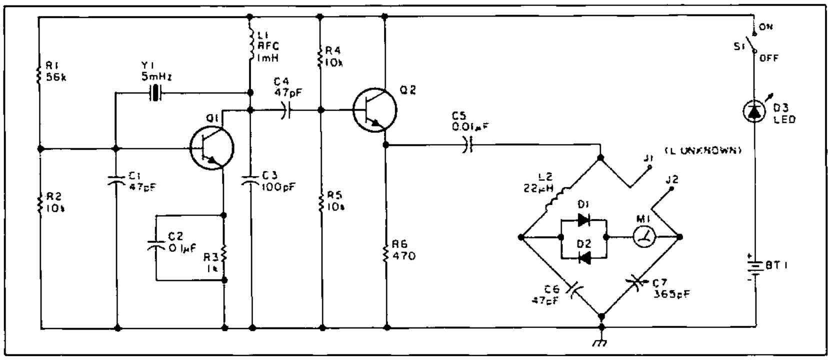

Figure 1. Schematic for the inductance bridge.

All of the circuitry can be constructed on a small piece of perf board, or a printed circuit board (such as Radio Shack 276-150). Keep RF wiring short and direct.

Install the binding posts J1 and J2 at one end of the enclosure, as far as possible from bridge tuning capacitor C7. *You want your fingers to be as far away as possible from the field around the unknown inductance being measured.*

Use stiff solid wire to connect C7 to J2, and from J1 to the junction of C5 and L2.

The 9 volt battery can be held in a clamp made for that purpose, or attached to the inside of the enclosure with a strip of Velcros™.

Parts Used

All parts used in this instrument, except the enclosure, came from my junk box (yes, I have a DEEP junk box, having been a ham since 1949). I used an aluminum box approximately 2" x 3" x 4" which I got for $1.50 at a hamfest.

Q1 and Q2 can be any small signal NPN transistors, such as 2N3904, 2N4124, 2N2222, etc.

L1 is an RF choke. Anything from about 390 µH to 2.5 mH can be used. The value is somewhat dependent upon the crystal frequency. Use a 2.5 mH choke at 1 MHz, or 390 µH at 10 MHz, for instance. The actual value is not of great importance as long as sufficient RF voltage is applied to the bridge.

L2 is a 22 µH RF choke; it's an important part of the bridge when a 5 MHz crystal oscillator is used to power it, as described earlier. Any 22 µH coil could be used here if its value is known accurately.

Meter M1 is a surplus FM tuning meter, center-zero, with a 200 µA movement. You can use any similar meter that's sensitive; 50-0-50 µA or 100-0-100 µA movements are suitable. Similar meters are available from Micro-Mart Inc., 508 Central Avenue, Westfield NJ 07090, and other mail-order dealers, for about $2.00. *[Ed. Note: A suitable meter is also available from Hosfelt Electronics, Inc., (800) 624-6464; part# MHE 5, the 100-0-100 µA meter.]* If you cannot locate a center-zero meter, there are numerous small edgewise and standard 100 or 200 µA meters which, with care, can usually be changed to indicate center zero. Carefully remove the cellophane tape holding the meter together and remove the front section to allow access to the movement. *Very carefully* push the long metal lever extending from the movement to one side while watching the meter needle. This will often allow movement of the needle to rest at the center of its scale. You may have to use needle nose pliers or the end of a screwdriver to move this lever. Use extreme care so you won't deform the lever or break the tiny spring attached to it.

CAUTION: These small edgewise meters, often calibrated in TV channel numbers, do NOT have a zero-adjust: DO NOT ATTEMPT TO USE A JEWELER'S SCREWDRIVER ON THE TINY SCREW AT THE CENTER OF THE MOVEMENT! This is a pivot screw, and tightening or loosening it may damage or destroy the meter movement.

Not all such meters can be modified to put the needle at the center, but most can be. Even if it is impossible to move the meter needle to the center of its range, if it can be moved a half-inch or so, it can be used, marking the meter scale at the new needle position as "zero."

Bridge tuning capacitor C7 may be difficult to locate if you do not have one in your junk box. Your best bet is to check with local hams and radio-TV repair shops. If this doesn't produce a usable capacitor, any hamfest should offer a wide selection. You may also find a suitable tuning capacitor from Fair Radio Sales, PO Box 1105, Lima OH 45802, (419) 227-6573 or from Antique Electronic Supply, (602) 820-5411; part# CV-230.

You can obtain crystal Y1, a 5 MHz surplus microprocessor crystal, from most mail-order dealers, as they offer a wide selection of these crystals of various frequencies. A 5 MHz HC-25 crystal is $1.25 from BCD Electro, PO Box 450207, Grand Prairie TX 75045-0207. They stock inexpensive crystals in the range of 33 kHz to 143 MHz, as do many other mail-order dealers.

C3	100 pF silver-mica capacitor
C5	0.01 µF disc capacitor
C7	365 pF variable tuning capacitor (see text)
D1,D2	1N914, 1N4148, 1N34A, 1N60, etc.
D3	LED
J1,J2	Binding post
L1	RF choke, 1 mH (see text)
L2	22 µH RF choke
M1	100–0–100 µA center-zero meter
R1	56k, ¼W, 5% resistor
R2,R4,R5	10k, ¼W, 5% resistor
R3	1k, ¼W, 5% resistor
R6	470 ohm, ¼W, 5% resistor
S1	SPST toggle or slide switch

Note: A blank PC board is available from FAR Circuits, 18N640 Field Court, Dundee IL 60118 for $4 +$1.50 postage. Please indicate this article when ordering.

The Mini-Keyer

A smaller and newer version of an old friend.

by Klaus Spies WB9YBM

Ten years ago, for a high school project, I built my first keyer using a schematic from Howard Berlin's *555 Timer Application Sourcebook, With Experiments*. When I upgraded to General, the keyer was a bit sensitive to 1 kW (the audio oscillator made a chirpy noise), but the unit served me well for many years. There were ample nooks and crannies behind which to hide this large box, but there came a time when I felt an upgrade was due, for several reasons.

First, most (if not all) modern rigs have a built-in sidetone oscillator, so I no longer needed one built into the keyer. Deleting this part of the circuit, as well as the speaker, made me curious to see how small the keyer could actually be made—not because I needed more room on my table (compared to my 2 kW amp and TR-7, even the original circuit was small), but to keep up with the modern trend of compactness and the design challenge it entailed. The keyer could very easily be powered from a regulator, so an unregulated, dirty and cheap wall transformer ($7 at Tri-State Electronics in Mount Prospect, Illinois, or about $9 at any Radio Shack) can be hidden away under the hamshack table, on the same bus the transceiver plugs into.

Although the majority of hams have a 12 volt power supply available in their shack to power their mobile VHF/UHF transceivers, I wanted to design in as much independence as possible into this keyer. If you want to use this keyer for Field Day, for example, it can be plugged into the same 110 volt generator powering the HF rigs, so there's no need to lug along a 12 volt supply. The only other option would be to power the circuit with a 9 volt battery, but who wants one of those things running out of juice in the middle of a QSO?

I also made a minor circuit modification. The dual NOR gates (the second acting as an inverter) were replaced with a single OR gate. Although the typical OR gate IC available on the market has plenty of gates to spare (there are four per package), it seemed to be poor engineering practice to use gates just because they were there. See Figure 1. A 6 volt relay can be driven by the 2N2222A transistor, if additional isolation is required or desired between the keyer and the HF rig.

For final assembly, I used a deep-drawn

Parts List

U1	555 IC timer
U2	74HC73 IC
U3	74HC32 IC
U4	7805 voltage regulator
Q1	2N2222A transistor
D1,D2	1N914 diode
R1	1k resistor, ¼ W
R2,R3	470 ohm resistor, ¼ W
R4	4.7k resistor, ¼ W
R5	50k potentiometer
C1	4.7 µF/35V electrolytic capacitor
C2,C3	0.047 µF ceramic capacitor
C4,C5	1.0 µF/35V electrolytic capacitor

Optional side-tone generator
(enclosed by dotted line in Figure 1)

U5	555 IC timer
R6	150k resistor, ¼ W
R7	3.9k resistor, ¼ W
C6	10 µF/35V electrolytic capacitor
C7	0.01 µF ceramic capacitor
SPKR	8 ohm speaker

NEW! Now you can NEW!

DRILL FOR SUCCESS

to pass Amateur theory and code exams

•Theory Drill Audio Casettes—Each set contains each question from the current pool with the correct answer -- available for Novice (2A) Tech (3A) General (3B) **19.95 for 1, 32.50 for 2, 39.95 for all 3.** (Please specify when ordering --both Novice and Tech sets needed for codeless Tech class. Questions requiring diagrams handled separately.)

•CW SIMULATOR for IBM PC—Up to 40 wpm—Custom Editor - QRM feature for real life simulation—requires 256K and DOS 3.0 or higher. **24.50 each.**

***HEIGHTS TOWER SYSTEMS are BACK!! Write for details.

Send check or money order only (no cash, etc.) to Ray Buchheit, KB8LBU, 12785 Pickerington Road, Pickerington, OH 43147

The Handy Inductance Bridge

Continued from page 12

All other components are items most hams already have on hand, or which can be found at Radio Shack. An excellent source for numerous small parts, components, and semiconductors/ICs is: Short Circuits, PO Box 285, Barnegat NJ 08005. Send them a postcard requesting their free catalog.

Calibration

The simplest way to calibrate this instrument is by connecting known values of inductance between J1 and J2, tuning C7 for a null, and marking the value on the dial. The circle cut from a panel to make a hole for a meter makes an excellent dial plate which can be epoxied to the tuning knob. You also might merely use a pointer knob and make calibration marks on the panel.

Most mail-order dealers carry a wide selection of small value RF chokes suitable for calibration. These are generally ±10% tolerance, sufficiently accurate for most purposes, and come in values from below 1 µH to around 3 mH. A few small RF chokes used singly, and in series and parallel, will provide numerous calibration points over the range of this instrument. Generally these chokes cost between 20¢ and 60¢ each, depending upon value.

Operation

With the instrument turned off, connect the unknown coil between the binding posts, J1 and J2. Rotate the bridge tuning capacitor C7 so the plates are fully closed—at the low inductance end of its range.

Turn the instrument on and note the meter needle swings to one side. Adjust C7 while watching the meter needle until the meter indicates zero. Read the value of the unknown inductance off the calibrated dial.

NOTE: *In some instances, when you tune C7 over its entire range, the needle may cross zero twice. The first zero indication when tuning from the low inductance range is the correct one.*

Assuming the bridge to be turned on and operating properly, if the meter needle does not move off center when C7 is tuned through its range, then either the coil being measured is open, or it is not properly connected to the binding posts.

If the meter swings to one side of zero and will not reach center as C7 is tuned through its entire range, then the inductance of the coil being measured is outside the range of the bridge—it's either too large or too small.

Cost

If all new (surplus) parts must be purchased, this Inductance Bridge should cost no more than ten dollars. This can be reduced by what you have on hand, can trade for, or get from other hams or at hamfests. ■

You may write to J. Frank Brumbaugh KB4ZGC at 82 Liddell Street, Buffalo NY 14212-1824.

Covert Hamming

A design for your next secret mission.

by Eldon Ryan K6BRP

Several years ago a major manufacturer of two-way radios designed a handheld exclusively for those with the need for unobtrusive communication, such as the FBI.

The radio had no internal speaker, microphone, or push-to-talk button. It was a handheld that didn't need to be hand-held. It could be concealed in a coat pocket or carried by belt clip. The PTT wiring was routed down the operator's coat sleeve and activated by a push-button in the palm. The miniature microphone was pinned under the necktie or lapel of the coat. The only telltale evidence of a concealed radio was the ear piece, which resembled a hearing aid.

This rig had a price tag of nearly three hundred dollars.

For less than five dollars, you can turn your HT into a device that operates on the same principles. You can use the remaining two hundred ninety-five dollars to build the other great projects that appear in *73*.

No originality is claimed for the following project, since the idea has been around and in use for some time. Numerous good articles have appeared about how to adapt Star Sets, Radio Shack headsets, booms, and mikes to your HT.

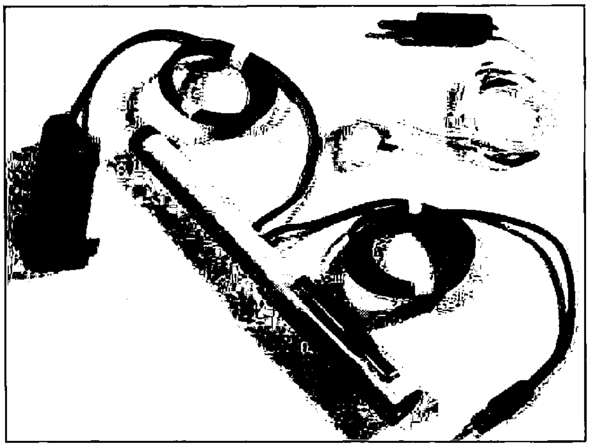

Photo A. The microphone may be concealed in a defunct pen housing. (Photo by Andy N6KAS.)

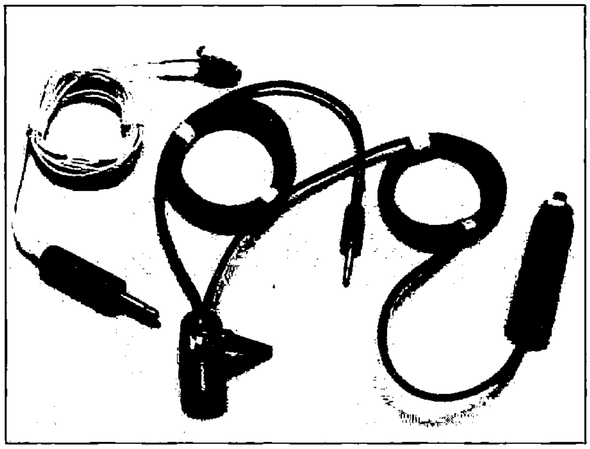

Photo B. You can also build the microphone into a phone plug housing. (Photo by Andy N6KAS.)

Let's go undercover....

First, here are two microphone design ideas: You could build it inside a defunct pen housing (see Photo A); or you could use the plastic housing from a quarter-inch phone plug (see Photo B).

The plastic "barrel" can be cut in half to reduce the size, and a mini alligator clip can be attached to the assembly with a very small self-tapping screw solidified with epoxy. The plastic barrel of a quarter-inch phone plug can also serve as a mounting for the PTT button switch (see Photo C).

Figure 1 is a schematic of an electret condenser microphone as it may appear in the operator's manual you originally received with your HT. Figure 2 is the schematic of the modified version.

Notice that the radio is keyed in series with the microphone.

A voltage is required for an electret microphone. This voltage, of course, is supplied by the radio.

It may or may not be necessary to decrease this voltage, the mike bias, but you can do it by placing a resistor of 1.5k or 2.2k ohms across the mike element. A 0.001 µF bypass capacitor may also be necessary. You can determine the correct value of the resistor by observing the deviation on a service monitor or deviation meter while speaking into the microphone. Keep in mind that you are not going to be talking directly into this microphone as you would your SPKR/MIC or the internal mike of your radio.

The microphone element can be a Radio Shack 270-090 or All Electronics Corporation MKE-2 (I recommend that you send for the All Electronics catalog. It's loaded with lots of goodies at bargain prices. See their ad in this issue).

Ignore the schematic on the back of the Radio Shack package, but DO observe polarity. The *high* side goes to the PTT button. Notice that there are no shields connected to the mike element.

The All Electronics element has

Continued on page 85

Parts List

2	24-inch lengths of shielded wire	RS 278-752
1	electret microphone element	RS 270-090
	or All Electronics Corporation	# MKE-2
1	momentary contact push button switch	RS 275-618 or equiv.
1	mike plug	RS 274-289 or RS 274-286*
2	¼" phone plugs, plastic housing	junk box
1	2.2kΩ ¼W resistor	junk box
1	0.001 µF capacitor	junk box
1	mini alligator clip	junk box

*Depending on the type of radio you have.

Note: The microphone and miscellaneous parts can be obtained from All Electronics Corp., P.O. Box 567, Van Nuys CA 91408. Telephone: (800) 826-5432.

Software for the Ham Shack, Part I

Useful ham calculations you can program yourself!

by Bill Clarke WA4BLC

The computer is commonplace in ham shacks. In fact, I would say that next to the old HF rig, it is the most common resident of the typical station. Over the next four months, I'm going to show you how to use the computer to aid you in building, repairing, modifying and designing ham equipment by doing your mathematical computations. Let's say that I am going to show you how to broaden the scope of computer usage in the shack.

Each month I'll include new computer programs. Each of these programs will consist of separate modules, or building blocks, that will become a ham radio computer system, menu driven and user friendly.

The program part for this month includes a portion of the MAIN MENU, a module for the design of antennas, and a module for measuring the physical lengths of transmission lines. Each month, as more modules are included, the MAIN MENU will grow.

Main Menu

The completed MAIN MENU will resemble this:

MAIN MENU FOR THE (your callsign)
HAM SYSTEM

1 - ANTENNA DESIGN MATH
2 - TRANSMISSION LINE MATH
3 - OHM'S LAW
4 - POWER FORMULAS
5 - EFFICIENCY FORMULA
6 - RADIO HORIZONS
7 - OHMS TO RESISTOR COLORS
8 - RESISTOR COLORS TO OHMS
9 - AIR COIL INDUCTANCE
X - FINISHED USING

ENTER YOUR SELECTION

Notice the place for "your callsign." After all, this is your system.

Module One

Antenna design is just about as basic to amateur radio as you can get. Without antennas there is no radio operation. Of course, some math is needed when designing dipoles, vees, quarter-waves, etc. In fact, math is even needed when cutting ground radials for vertical antennas. This program module asks the user to enter a frequency (in MHz), to which it then responds with the electrical wavelength for that frequency. Additional responses include all the normal fractional wavelengths (½, ¼, etc.). The dimensions for a dipole cut to that frequency are given, as are the measurements for radials.

Module Two

Many recent antenna articles call for a quarter wavelength of transmission line for one reason or another, usually as a matching transformer. As in the antenna module, the user is prompted to enter the frequency of design. The computer responds with physical lengths for quarter- and half-wavelengths of the popular coaxial transmission lines in use today. This module bases its computations on velocity factors.

About the Programs

The program modules given in this series of articles are written in BASIC. Most hobby computerists understand BASIC, and their computers understand it as well. It is a relatively universal language, usable on IBM ™, clones of them, Atari ™, Apples ™, and the Commodore ™ series of computers. It may well be, however, that some slight modification to the programs will be needed to run them on your particular machine. Although written in GW BASIC for use on a clone, I have attempted to make the programs as transportable between the various brands as possible. Program modifications are noted for the Commodore at the end of each article in the series.

Entering a Program Listing

Entering a program listing into your computer is very easy, although it calls for exacting accuracy. No mistakes can be tolerated. To err will cause a failure sooner or later. Generally sooner!

Depending on the system you have, set it up to operate on BASIC. Once ready to operate in BASIC, type in the listing as it is given. For example:

```
10 PRINT "MAIN MENU"
```

What you actually type is: 10 space PRINT space "MAIN space MENU" (the quote marks get typed also). Then you press ENTER (or the RETURN key on some machines). In other words, type exactly what you see. Be sure to type in capital letters, just like the program listings show.

That's all there is to it. Of course, there are quite a few lines to enter, so take your time and be careful. Oh yes: *In line 12, type your callsign in place of the six X's.*

After you have completed typing in all the lines, you must SAVE your work.

Alternative methods of program entry, such as WordStar in nondocument mode, are permissible.

Saving Your Work

Saving a program is very simple. Place a FORMATTED blank disk in the disk drive, then type SAVE "HAM1" (on the Commodore, type SAVE "HAM1",8) and press ENTER. HAM1 is the name we are giving to the first section of the overall HAM program.

There is a reason for saving a program before trying to use it. This will all become very clear in a few minutes.

Using the New Program

LOAD the new program by typing LOAD "HAM1" (LOAD "HAM1", 8 on the Commodore) and pressing ENTER. When the computer signals READY on the screen, type RUN and press ENTER.

The next thing you should see is the MAIN MENU for your new Ham System. It should show three selections: ANTENNA DESIGN MATH, TRANSMISSION LINE MATH, and FINISHED USING. Go ahead and put the program through its paces. Try a few frequencies for test purposes.

HINT: If the menu selections fail to respond, try locking the keyboard into upper case (caps).

Should you enter into a menu selection you don't want, press the ENTER key until a small menu appears in the lower left corner of the screen that gives you the option to press M for MAIN MENU.

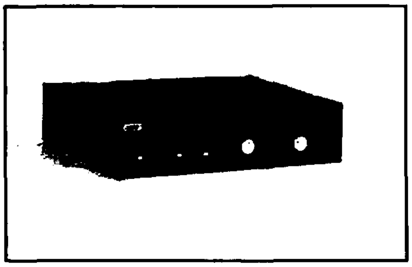
If you have an error in anything you see on the screen, such as wording, typos, or a computer failure or lockup, then reset the computer. Again LOAD the program (as before). However, instead of running it, you will LIST it. Listing shows everything you typed in from the program listing. To list: type LIST and press ENTER.

Sometimes when a program fails, it will cause the computer to halt operation completely. This is called a lock-up. The only way to get it going again is to reboot it. Rebooting usually equates to turning the computer off, then back on. This will cause a complete loss of all data and programs that were in the computer's memory. If you had not saved your program to disk, it would be gone. To get it back, in that case, you would have to re-enter it from the listing. Now you see why the program was saved before it was run. ALWAYS SAVE YOUR WORK BEFORE RUNNING IT.

While checking the listing, if you see an error, use the CURSOR keys to move the cursor to the incorrect line. Make the correction, then press ENTER. ENTER is pressed

REVOLUTIONARY

is the only word to describe this:



The NIR-10 is a Noise/QRM Reducer for SSB VOICE! It is the only device available that can reduce noise and remove heterodynes occuring in the presence of speech. What makes this possible? Real-Time Digital Signal Processing (DSP) using a 40 MHz DSP chip!

•The NIR-10 is a DSP audio processor that connects to the audio output of your receiver or transceiver and includes a built-in Speaker Amplifier.

•Automatically Enhances Voice Reception by Reducing or Eliminating:

Heterodynes & Tune-Ups
White Noise
Ignition Noise
Power Line Noise
RTTY Interference
"Woodpecker"

•Includes a Bandpass Filter Mode to Enhance CW and RTTY. Forms a Variable Center Frequency Digital Filter with Selectable Bandwidth. Provides performance that analog filters can't match!

•Work More Stations: Allows Reception of Otherwise Unreadable Signals!

•Reduces Listener Fatigue.

• A Must for DXers, Contesters, and Field Day Ops.

Order direct:
NIR-10: $395; with 12V AC Adapter add $12. We pay shipping.

Line Modifications for the C-64

The following commands must always be replaced as shown:

```
SPACE$(**):  must be removed.
Example: 12 PRINT "MENU FOR THE XXXXXX HAM SYSTEM"

CLS  replaced by  PRINT "[shifted]CLEAR/HOME".

CLEAR  replaced by CLR

M$ = INKEY$  replaced by  GET M$ : IF M$ = "" THEN (line number)
Example: 30 GET M$ : IF M$ = "" THEN 30

replace the word DIMENSION with SIZE
```

Other modification lines are typed as they appear below:

```
 33 IF M$ = "X" THEN END
231 PRINT "1/4 WAVE"
232 PRINT "RG8        "FNA(B)
240 PRINT "PRESS ANY KEY FOR MORE" : GOSUB 290
241 PRINT "1/2 WAVE"
242 PRINT "RG8        "FNA(BB)
290 GET Z$ : IF Z$="" THEN 290
291 PRINT "[shifted CLEAR/HOME]" : RETURN
```

Continued from p. 22

for each line that is corrected. After all corrections have been made, SAVE the program as you originally did. However, give it a new name: HAM1A. Some computers will not accept programs of the same name on a single disk. Later, after you are satisfied that all is correct with the latest saved version, go back and erase the error-ridden versions. Then re-name the good version HAM1.

Well, that's all for now. Happy typing and running. More will follow next month. *[Ed. note: This month's listing, "HAM1," can be downloaded from the 73 BBS. Phone: (603) 525-4438 (73mag SIG).]*

You may reach Bill Clarke WA4BLC at RD#2 Box 455-A, Altamont NY 12009.

You can subscribe to 73 by phone. Call 1-800-289-0388.

Two QRP Transmitters

Dust the ethers and bend the waves!

by Charles D. Rakes KI5AZ

Here's two hot little CW QRP transmitters that you can build in an evening or two, then enjoy spanning the globe in milliwatt slippers for many moons and not be out much loot to boot.

The first and more complex of the two QRP transmitters is the 80 meter "Color Burst Ether Duster." It spurts out over 1 watt with full break-in operation. Two 7400 TTL ICs and four 2N3904 transistors control the electron flow.

The second and simplest transmitter is the 40 meter "Wave Bender" that operates with one IC and two transistors, to massage the antenna with about 500 to 750 milliwatts. This transmitter requires either a manual transmit-receive switch or a separate TX and RX antenna system.

Both circuits can be tailored to operate in either the 40 or 80 meter band by changing the crystal (XTAL) and output filter.

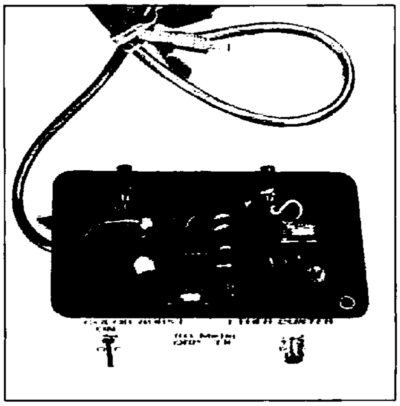

Photo A. The Color Burst Ether Duster.

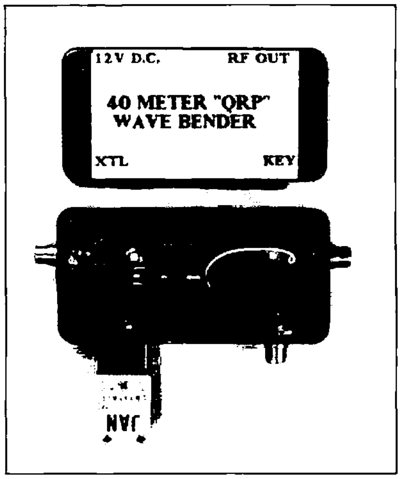

Photo B. The 40m Wave Bender.

Building the Ether Duster

Before starting construction, take a gander at the schematic diagram in Figure 1. Become acquainted with the circuit while your iron is heating up.

Short leads and neat wiring is a must if you choose to build your transmitter breadboard style. But if you take the easy path and use a PC board, construction will be a breeze. Just follow the component placement layout shown in the PC foil pattern drawing in figure 2 and stuff the parts in place. Take extra care in soldering in the two ICs so you don't end up building an unwanted solder bridge between pins.

The output filter coil, L1, is made by winding 24 turns of #26 copper enamel wire, evenly spaced on a T50-2 toroid core.

A Radio Shack deluxe plastic project case (RS 270-221) houses the transmitter in fine style. To duplicate this unit, just follow the general layout in the figure. RCA phono jacks are used for the key, antenna, and receiver connections. A mini-DPDT toggle switch turns the transmitter on, and a three-wire cable with mini-gator clips makes a handy battery connector.

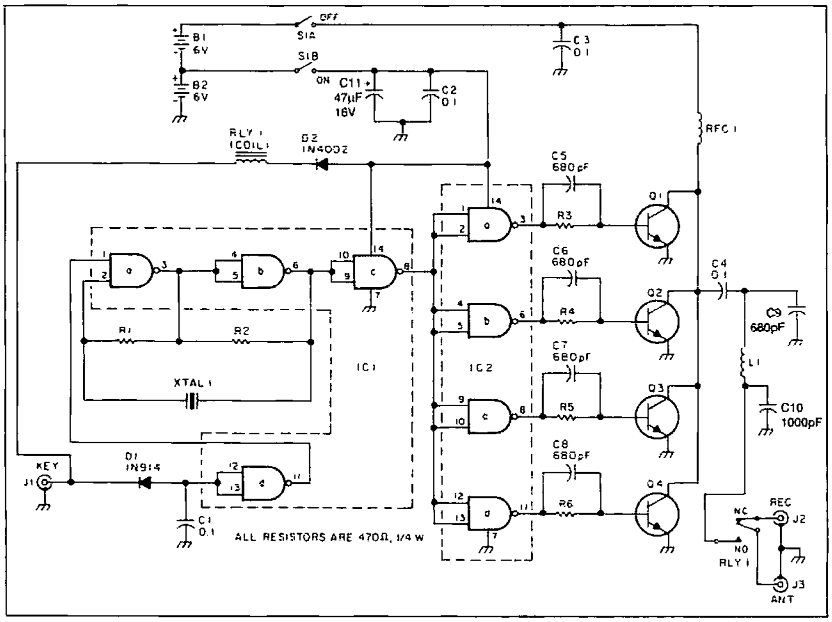

Figure 1. Schematic for the Color Burst Ether Duster.

Firing up the Ether Duster

Two 6-volt lantern batteries connected in series supply power to the circuit. The 6-volt junction between B1 and B2 supplies power to the two ICs. The full 12-volts power the four output transistors.

Connect a 50 ohm, 2 watt (two 100 ohm, 1 watt carbon resistors in parallel) load to the antenna jack and a current meter (500 mA range) in series with the +12 volt battery lead.

If you have an oscilloscope, monitor the RF output. Key the transmitter, and the current meter should read between 150 and 225 mA. A 20 to 30 volt peak-to-peak 3.579 MHz sine wave should then appear on the scope. A 20 volt peak-to-peak output translates into about 1 watt; a 25 volt signal is close to 1.5 watts; and a 30 volt output is about 2¼ watts.

Should you luck out and end up with a stubborn crystal that doesn't start each time the key is closed, just add a 15 to 25 pF capacitor between pin #6 of IC-1 and ground.

Full break-in operation occurs each time the key is closed, with the mini-relay operating in step with each dit and dah. The antenna is transferred from the receiver to the trans-

XTAL	Any 40M crystal	

Misc. Radio Shack plastic cabinet, RS 270-220; wire, solder, circuit board, batteries, etc.

You can get the 40 meter Wave Bender, including the circuit board, in kit form from the author at Krystal Kits for $14.95 postpaid. You will have to furnish the enclosure, jacks, crystal, and socket to complete your transmitter. A PC board only is $5.25. See Table 1 for the address.

mitter's output with each key closure and back, to receive in the key-up position.

The Color Burst Frequency

You might wonder why anyone would want to operate a QRP transmitter on a frequency that every color TV set in the country generates. Good question. Well, first, it's a legal 80 meter frequency, and second, there is an unlimited supply of cheap-to-free 3.579 MHz crystals from secondhand and junk color TVs. And if you monitor the frequency for a while, you'll hear a lot of CW activity, including a couple of nets. It's another challenge for the QRPer! I'll be looking for you on the Color Burst frequency.

The 40m Wave Bender

The Wave Bender transmitter is about twice as easy to build, especially if you use a PC board. Just follow the layout in the figure and solder each component in place.

The output filter coil, L1, is made by winding 20 turns of #26 copper enamel wire evenly spaced on a T37-2 toroid core.

The completed circuit board fits snugly inside Radio Shack's deluxe plastic project case (RS 270-220). The battery input, the key, and the RF output connections are all made through RCA phono jacks mounted to the enclosure.

The XTAL socket is also mounted in a similar fashion.

Plug in a good 40 meter crystal, and connect a 50 ohm, 2-watt load to the RF output. Connect a milliampere meter (0 to 500 mA) in series with battery positive, and close the key. If you're not in cahoots with Murphy, the current meter should read between 125 and 160 mA on key-down, and about 25 mA on idle. The RF across the 50 ohm load should be between 15 and 20 volts peak-to-peak, for an output of 500 milliwatts to slightly less than 1 watt.

The 40 meter Wave Bender is basically the Color Burst circuit cut in half. See Figure 3, the circuit diagram. All you need are two transistors and one IC. There's no provision for break-in operation. Just about any fundamental-cut crystal will oscillate in the circuit; the readily available and inexpensive FT-243 type of crystal was my choice.

A 7805CT 5 volt regulator simplifies the battery hook-up, which also allows the circuit to operate with an input of 8 to 12 volts. By changing the supply voltage, the RF output can be set for a special QRP power output level.

Now for the real fun—making that very first contact with your very own home-built QRP transmitter. Good luck, and 73s from KI5AZ down in the Ozarks and back in the hills.

Charles D. Rakes KI5AZ, PO Box 445, Bentonville AR 72712.

A Better Tube Tester

Check more than just DC amplification.

by John Shelley WA1IAO

Even in these days of increasingly sophisticated solid state equipment, many hams still buy and use tube-type equipment. There's a lot of perfectly usable old gear at hamfests you can pick up. Still, you need to be able to check it.

Most hams use GM (transconductance) tube checkers in their shacks. I cringe when I see someone buying a military or commercial checker at a flea market, because I have gotten very few accurate readings from them in my thirty-odd years of using them.

How could these boxes with all their switches, knobs, and meters not solve the mysteries of the glowing bottles? Simply put, most checkers were designed to test the tubes as if the tubes were DC amplifiers, and there is too much cumulative error built into them. The worst part is that they lack a sensitive leakage test.

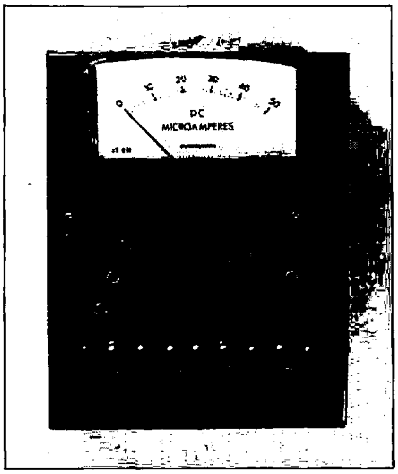

Photo A. The completed tube tester.

Checking Tubes

I watched military tubes deteriorate. Commercial tubes soon followed. For instance, Western Electric made quality tubes for their Nike missile system, but other manufacturers soon outbid them, with disastrous results. At one time in the sixties, Congress tried to withhold funding for military systems because their inspections had shown that the average time between failures was six hours. The resulting hue and cry, along with promises of great breakthroughs, was sufficient to push the budget through, however. The problem lay in there not being a valid test for tubes.

A Tektronix field engineer once held a seminar at our shop to help us learn how to fully use their instruments. Ours was the first facility at which he found all circuits properly calibrated and operating. The calibration of a 545 scope, for instance, is a cumulative process. Every step depends on obtaining the proper adjustment and using quality parts in its construction. The probability of their changing value or tuning by themselves is practically nil. The many tubes involved, however, can cause profound changes due to contaminants.

It was awful seeing technicians chasing contaminants and repeatedly adjusting pots, hoping that the reading would suddenly pop into specs. It drove some to despair: A Hawaiian National Guard Technician reportedly tried to charm a defective radar scope into operation by chanting and shaking a tea leaf at it!

To many, the 10-channel AN/GRC-27 was a monster. But once tuned with clean tubes, they were easily managed by periodically purging them of leaks—little or no retuning required!

The worst example of equipment failure I ever found was in the ACV/TVM model ME-6c/U. Its amplifier tubes were 6BH6s, and I never found a good one in JAN (military) stock. The meters were totally useless because, with those tubes, they would do nothing but oscillate or freeze against the pins.

Finding Leaks

My tube checker uses high sensitivity to look for leakage. It is small, easy to build, and it finds bad tubes ranging from audio amplifiers to UHF oscillators. Using a voltage near B+ potential, the tester tries to read it through the (presumably) empty spaces between elements. (Note: The large, octal, transmitting-type tubes are not included in this discussion; they are better tested in-service.)

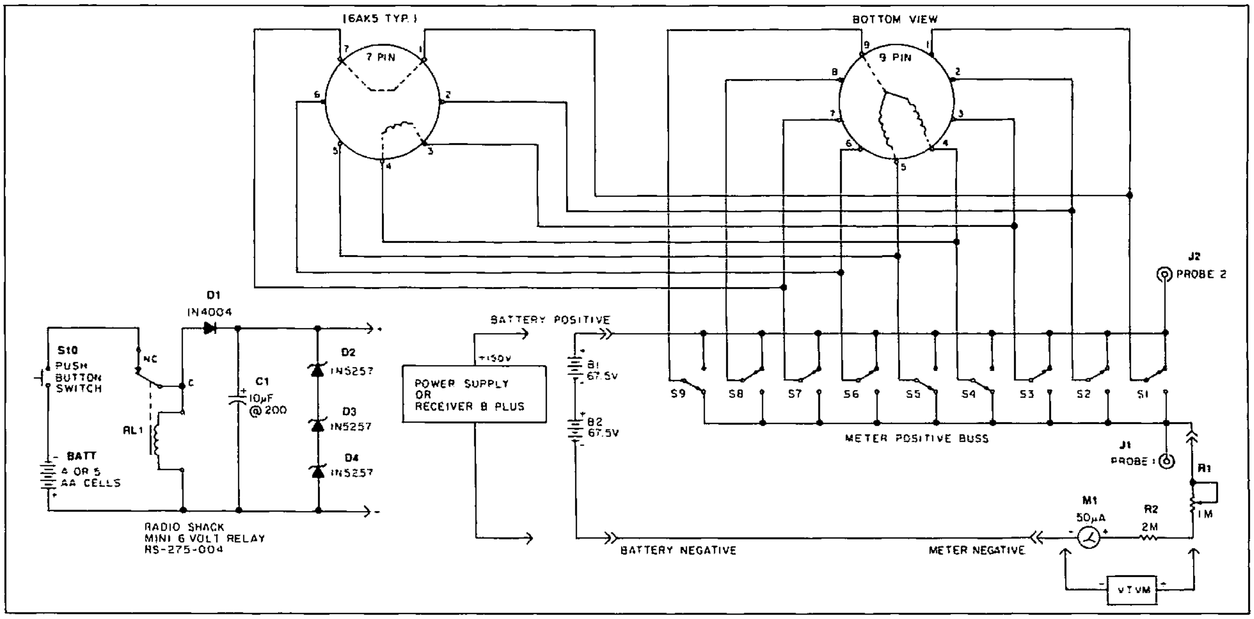

Figure 1. Schematic diagram of the tester.

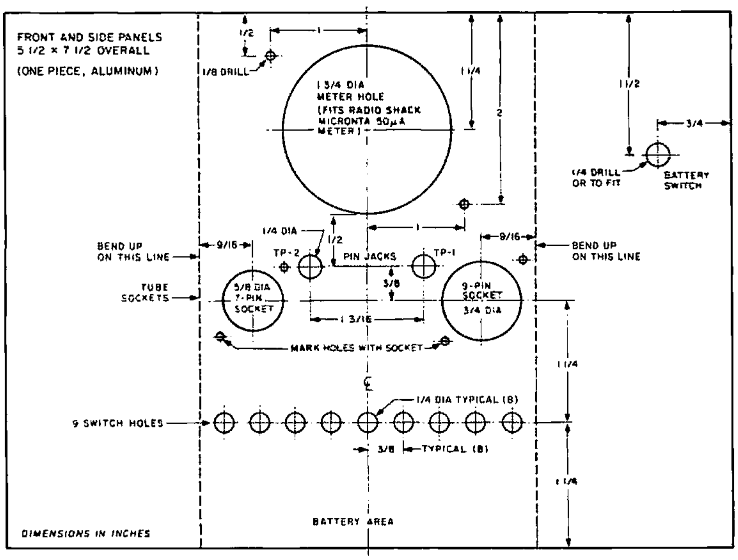

Figure 2. Front panel drilling template. Note that the Radio Shack meter has been discontinued. Use dimensions to fit your particular meter.

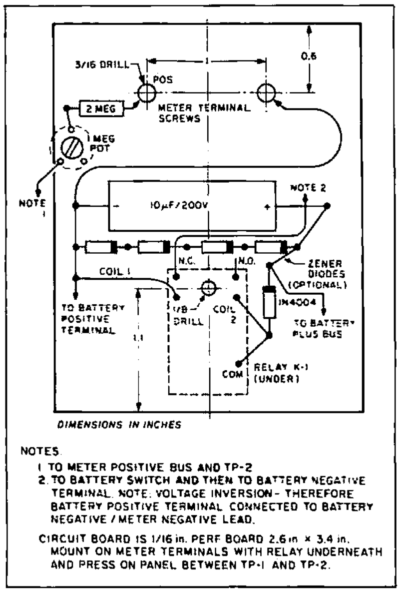

Figure 3. Internal circuit board parts placement. All parts mounted on perfboard. (Note the optional parts if using Option A on Figure 1).

By accident, I discovered how leaks cause malfunctions. There was a walkie-talkie battery on my workbench, with a set of test leads attached to the 135 volt terminals. We used it to test electrolytic capacitors at near-working voltages. At one time, it detected a group of leaky, screen-bypass capacitors which had prevented us from obtaining proper sensitivity figures in a series of receivers we had to maintain.

One day I was checking out a receiver someone had brought in after unsuccessful attempts to stop it from buzzing. He checked the filters and tubes, to no avail. With the small amount of knowledge I had then, I attacked the problem. Hoping to find a motorboating capacitor, I isolated the B+ lead from the power supply and attached a VTVM in series with the battery, and the B+ path to ground. There was a leak! Why, though, was it not oscillating?

Next, I removed the tubes to prevent breakage while I unsoldered the capacitors. Lo and behold, the leak disappeared when I removed the first tube. Sure enough, there was a leak between the filament pins and one of the grids of the mixer tube. Apparently the 60 Hz from the filament was modulating the local oscillator, and sending the products down through the IF and audio circuits.

As time went on, I found leaks in many tubes, bridging all possible combinations of elements. I soon found it necessary to build a switch box containing a battery and sockets, to eliminate the hassle of manipulating the tubes and test leads in my hands. This became the mainstay of our Signal Corps repair shop, and later, the Ordnance missile radar shop. We practically eliminated troubleshooting, except for shorted electrolytics and obviously broken or burned parts.

Construction

If you own some pieces of tube equipment, you should at least build a portable checker. In its simplest form, it uses a 50 μA meter movement instead of a VTVM. This provides reasonable sensitivity, and will fit into a hand-held box. You can take it to flea markets and save yourself from disappointment by testing tubes before you buy them.

See Figure 1. The dotted filament on the 9-pin diagram shows the most common arrangement of a 9-pin tube. S-4, S-5, and S-9 are shown down, to allow you to check leaks from the filament to all other pins. Similarly treat the most common 7-pin tubes by pushing down S-3 and S-4 simultaneously. Multiple pins for any element should be switched together. Otherwise, the common connections will short. The control grid of a 6AK5, for instance, has connections to both pins 1 and 7. Actuate all other switches singularly to look for leakage paths. When a switch is down, lightly tap the tubes to bring out indications that may may be temporarily hidden. Then, return the pin to the up position before going on to the next one. Pin jacks TP-1 and TP-2 are used to check tubes that have non-standard bases, using test leads.

I suggest that the panel, at least, of the box be made of metal and connected to the battery's negative terminal.

A tester can also use the leads to find leaks in capacitors and even in wiring. Once I found a leak that had confounded technicians. They were searching for whatever had caused a circuit to overload a power supply, and they had found nothing with an ohmmeter except the 135 volt feed wire to the circuit. Probing the wiring, however, caused variations in the meter reading. I found a charred area hidden where the insulation of a wire came in contact with a metal part. It seems that a nearby lightning strike had arced through and disabled an entire radar system. It is unfortunate that we cannot use a high potential on modern, low-voltage circuitry, to find breakdowns such as these.

Parts List

S1-S9	SPDT toggle switches
J1,J2	Test jacks
R1	1MEG potentiometer
R2	2MEG resistor
M1	50 μA panel meter
Power supply	
—Option A:	
S10	Momentary contact switch
RL1	6 volt relay (RS# 275-004)
D1	1N4004 diode
D2,D3,D4	1N5257 zener diode, 33 volts at ½W
C1	10 μF/200 volt electrolytic capacitor
—Option B:	
Any 90 to 150 volt DC supply	
—Option C:	
B1,B2	67.5 volt batteries in series (Eveready #416, Newark Electronics #49F1009)

Points To Remember

Some important points are in order. One is that sunlight causes conduction in some tubes, and they should be shaded during testing. Another is that they should be clean, especially between the pins. Holding them in perspiring hands just before testing them will show leaks, as will not letting them cool off for at least two minutes after operation. Each switching operation causes a capacitive kick on the meter, and each user will have to decide on a tolerable residual reading for his particular setup.

Also, if solder flux other than rosin is used to build the tester, all socket pins will show leakage—permanently. Surprisingly, some leakage paths show diode characteristics, so a thorough test would require starting with all switches down and sequencing them upward in addition to the initial test.

In spite of their high-power consumption, tubes are one of the greatest inventions in history. When not contaminated, they give many years of reliable service. ■

The JPS NIR-10

Separate the words from the noise.

JPS Communications, Inc.
P.O. Box 97757
5516 Old Wake Forest Road
Raleigh NC 27609
Tech Info: (919) 790–1048
Orders: (800) 533–3819
Price Class: NIR-10, $395;
AC Adapter, $12, including shipping.

"All you ever do is listen to noise!" Is that how people have described your hobby? Now, thanks to state-of-the-art digital signal processing, you don't have to listen to that complaint—or to most of the noise—anymore.

The JPS NIR-10 Noise/Interference Reduction Unit is the first unit on the ham market to identify what human speech sounds like, then separate it from most of the other stuff on the band: ignition and power line noise, computer noise, heterodynes, and even the white noise generated by atmospheric conditions and within the receiver. It won't make listening to 75 meter sideband sound like your local FM broadcast station, but under reasonable conditions the constant racket under single sideband voice signals will hardly be noticeable anymore. If you've been hearing that same noise for more than 30 years, as I have, you may not even think about it, but noise is fatiguing. It has left me with a ringing in the ears—even after an interesting QSO.

The NIR-10 won't take a signal that's down in the noise and magically bring it out into the clear (one of my fondest dreams). Its biggest improvement is on signals at least one-half to one S-unit above the noise, where there's enough speech information to extract. Take a quick look at the before and after oscilloscope plots in Figures 1 and 2. In each, the top trace is the noisy HF sideband signal from the receiver; the bottom trace shows the audio output of the NIR-10, cleaned up and slightly delayed.

The NIR-10 is wired up between your receiver's speaker output and its speaker, just like a standard audio filter, although JPS doesn't want you to think of the unit as a filter in the normal sense of the word. Actually, the NIR-10 has two modes: the NIR mode which separates the speech sounds from the noise, and a bandpass mode which acts as a very selective filter.

The bandpass mode is intended primarily for nonvoice modes, and provides a choice of three bandwidths and a variable center frequency. Since digital signal processing (DSP) is used for the bandpass filter, the sides of the filter's slope are very nearly straight when plotted on a graph showing bandwidth versus amplitude. Ultimate selectivity is achieved at just slightly beyond the three bandwidths of 200, 600, and 1,500 Hz.

The bandpass mode performs well and is sharper than the analog or switched-capacitor designs I've used, but most of this review concerns the NIR mode, since that's what really makes the product unique.

Getting Started

The NIR-10 is a small black box, 2" x 7" x 6" (HWD) that will sit discretely atop your rig. This is probably the best spot for it, since you will be frequently manipulating the controls.

Hookup couldn't be easier: Audio from the receiver goes into the input jack, and your station speaker goes to the NIR-10 output jack. All that remains is to feed in power from the optional wall transformer or your regular station supply, 11 to 15 volts DC at 1 amp peak. Then you turn the receiver volume control up to the point where the NIR-10 "peak" indicator begins to flash on voice peaks, and from then on use the NIR-10's volume control to adjust the speaker level.

A toggle switch moves the NIR-10 between bypass, bandpass, and NIR modes. When in NIR mode, a rotary control also adjusts the level of interference reduction; the same control adjusts the device's center frequency when in bandpass mode. The rest of the front panel includes a three-position bandwidth switch for the bandpass mode, a headphone jack, and the on/off switch.

The World of Noise

The big problem with noise reduction is that there's an infinite variety of different types of noise. Any noise reduction scheme must represent the designer's best guess on what the difference is between the noise and the desired signal. You've probably noticed how the noise blanker on one rig works better on particular types of noise, and a different rig can best eliminate a different sort of noise.

As the NIR-10 tries to separate noise from speech sounds, it runs into the basic limitation that speech corrupted by noise doesn't sound much like speech anymore. So if there's not much difference between the noise and the signal, there's not much it can do, and removing the noise leaves you without an intelligible signal. Depending upon the specific noise, the NIR-10 will produce its most impressive noise reduction when the desired signal is about one S-unit stronger than the average noise level. JPS specifies that the NIR-10 is capable of up to 20 dB of white noise reduction, and 40 dB of tone elimination. Keep in mind, though, that the inherent limitation of the NIR-10 is that the stronger the signal, the more noise it will eliminate.

The NIR-10 does a superb job on ignition interference, where cutting down the typically high noise level makes for far easier listening. While the NIR-10 will reduce tones and heterodynes, it won't get them all the way down, as a notch filter will. Keep in mind, however, that a notch filter will only handle one tone, while the NIR-10 will reduce all the tones it finds.

On the other hand, since adjacent channel splatter from other stations is a form of speech, the NIR-10 won't reduce them at all; its NIR mode does not reduce bandwidth beyond the 3.2 kHz it normally passes. So, a notch filter and a conventional bandpass filter are still useful. I find they work better if they act on the signal before it gets to the NIR-10. A noise limiter is still useful, since some types of static crashes are too fast for the device to respond to.

The NIR-10 works on speech, so it will work fine with AM, FM, and SSB, but music is pretty badly chopped up. You can still generally hear the speech component of music, and that's useful if you're trying to ID a broadcaster.

Note that the action of the digital processing produces a delay between the input and the output signals of about 130 milliseconds. This isn't normally a major problem, and you'll quickly get used to a backlash-type effect as you tune around. It does, however, make the unit unsuitable for fast turnaround modes, such as two-way AMTOR.

Seeing the Effect

To illustrate the effect and create Figures 1 and 2, I used a LeCroy 9410 digital oscilloscope. I tuned the receiver to a sideband station, and displayed amplitude in the vertical axis and time in the horizontal, using a plotter to create a printout. The top trace shows the

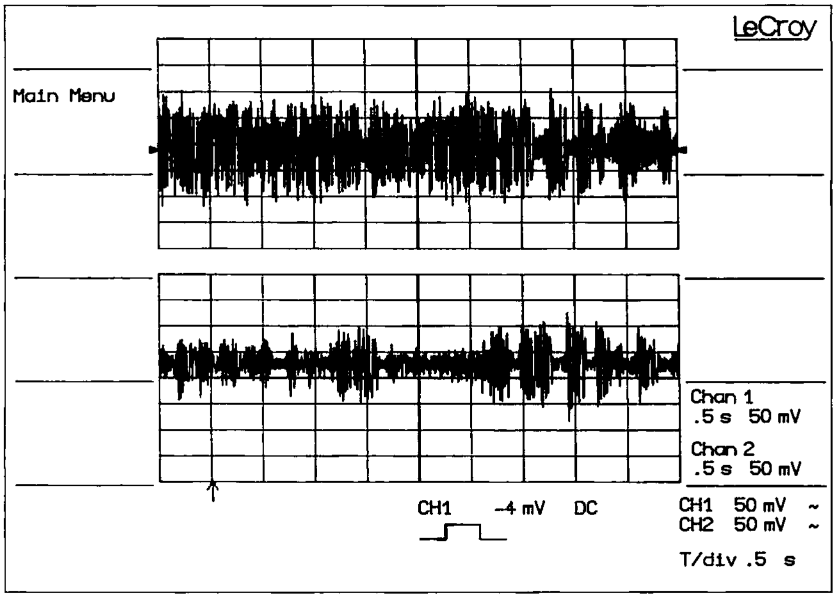

Figure 1. A 20 meter sideband signal partially covered with power line noise. Note the difference between the top trace, the input to the NIR-10, and the bottom trace, showing the cleaned-up output.

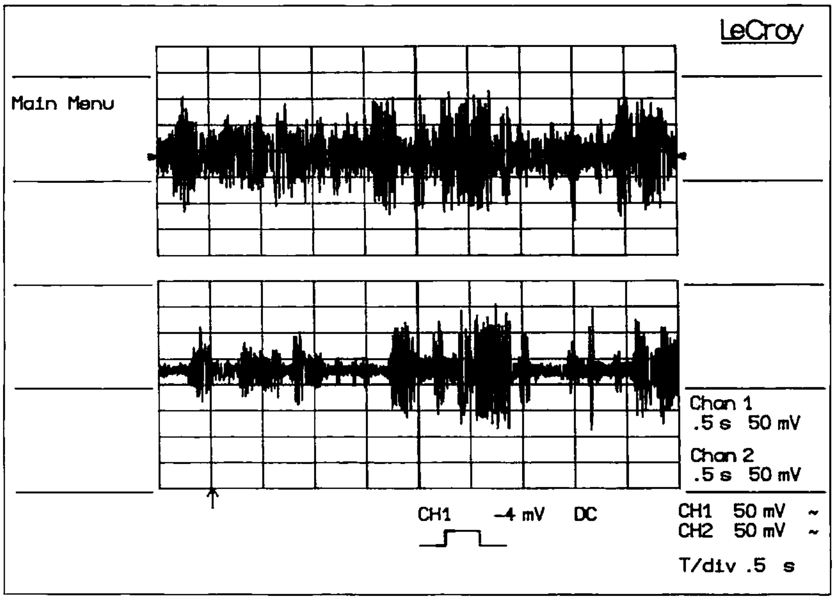

Figure 2. A 40 meter sideband signal during the midday (top trace). The bottom trace shows the results after processing by the NIR-10. The increased dynamic range between the signal and noise is quite obvious.

All scope traces taken with a LeCroy 9410 digital oscilloscope contributed by John Seney WD1V.

audio input to the NIR-10; the bottom the output.

Figure 1 shows a 20 meter signal with a severe local power line noise, mostly in the first half of the trace. The NIR-10 had no trouble eliminating it, leaving something close to a normal speech pattern.

Figure 2 shows a 40 meter midday QSO with more random atmospherics. You can easily see the speech waveforms and their amplitudes preserved, while the noise between the speech bursts is greatly reduced. You can also clearly see the offset between the input and output traces, showing the unit's internal delay.

What the plots don't show is the effect of adjusting the NIR level control. A signal close to the noise level would allow only a small amount of noise reduction, perhaps in the 9 o'clock position of the control, before it becomes too choppy to be intelligible. As the signal becomes stronger, you can turn up the control for more noise reduction, with most signals optimized with the NIR control at about 12 o'clock.

As the noise reduction takes place, you'll notice that the remaining noise sounds a lot different than you're used to, primarily because it has been "de-randomized" into low-level, very short-duration tones described as "beedely-beeps." It's not annoying, just different.

CW operation is improved in the NIR mode, too, except for slow CW, which the device will try to attenuate. By greatly reducing the noise, copy via a computer system such as a multimode TNC produces a lot fewer errors.

Operating Notes

JPS has cleverly provided the capability to switch the NIR-10 into bypass mode electronically, in addition to using the front panel switch. Thus, you can connect the "remote bypass" to the push-to-talk line of your rig and monitor your transmissions without the delay.

The NIR-10 can also be used for transmitting, providing a more effective method of communicating in a high-noise environment than a noise-canceling microphone. You'll have to work up your own switching scheme if you want to use the same unit for both transmitting and receiving.

JPS provides a concise but complete manual, describing both the hookups and the philosophy of the NIR-10's design and operation. This approach is especially valuable because the NIR-10 represents a new category of equipment on the market. A partial schematic is included for troubleshooting the simpler parts of the set; a block diagram illustrates the actual DSP logic.

Even in bypass mode, the NIR-10 still works as an amplifier and the volume control is in the circuit, meaning it has to be powered up in order to hear anything fed to it. It's a minor quibble, but I find setup and troubleshooting simpler when things are completely out of the circuit when bypassed.

All digital devices tend to create noise of their own, and the NIR-10 under test did produce some digital noise on a nearby broadcast radio, although there was no noise detectable on my ham equipment when attached to an external antenna. JPS says improvements in shielding and filtering have greatly reduced this effect in current production units.

Physically, the NIR-10's workmanship is excellent and shows evidence of the JPS commercial equipment line, from which it's been adapted.

It's Worth Having

We're going to be seeing a lot more of digital signal processing in our communications equipment, and it's fun to think about a future where we can sit at a keyboard and optimize all possible signal conditioning parameters to combat any interference. On the other hand, I have a half dozen audio filters and sometimes I think all they do is provide knobs to turn when there's no signal to hear.

At no time was there ever a signal I could copy with the NIR-10 that was unintelligible without it. Yet the NIR-10 requires minimum tinkering and does exactly what it is supposed to do: make ham radio contacts easier to listen to. If you are tired of all the noise in your ears, and especially if you spend a lot of time listening, then the JPS NIR-10 is worth having. 73

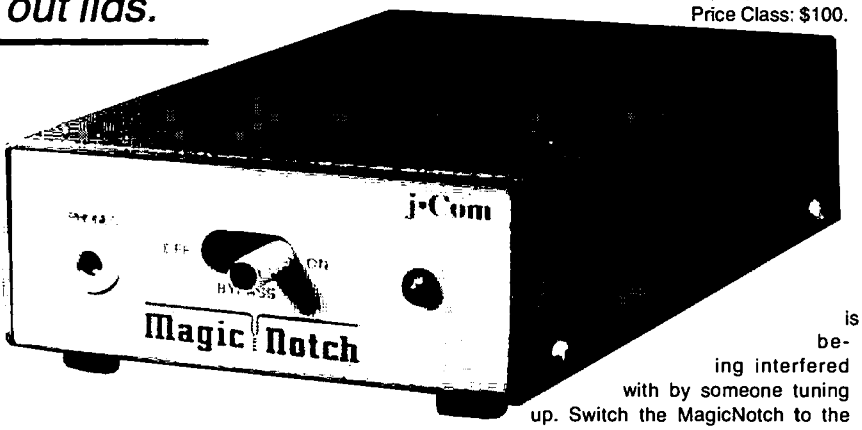
The J•Com MagicNotch Audio Filter

A little box that locks out lids.

J•Com
P.O. Box 194T
Ben Lomond CA 95005
Tel. (408) 336-3503.
Price Class: $100.



Amateur radio is full of gadgets. We have gadgets to measure things, gadgets to amplify things, gadgets to attenuate things, as well as gadgets to help us make other gadgets work better.

Some gadgets end up at the bottom of the closet or drawer. They may operate as advertised, but once you get them installed, you realize that what they do is something that doesn't really need doing. Other gadgets become a permanent part of your setup, because the manufacturer has solved a particular problem. J•Com's MagicNotch audio filter lands firmly in the second category. It's a simple solution to a very irritating problem: interference from a continuous carrier heterodyne signal (like when someone tunes up on top of your QSO).

The MagicNotch is an automatic notch audio filter. It requires no tuning, calibration or attention of any kind. You simply place it in between your rig and an external speaker, supply 12 volts, and turn it on. When the MagicNotch detects the presence of a continuous carrier, it filters it out with a very sharp notch filter. Audio of other frequencies, such as speech, are unaffected and pass through the filter without attenuation.

How It Works

According to the folks at J•Com, the MagicNotch uses a switched capacitor active filter (SCAF), which is scanned through your rig's audio output. A control circuit monitors the filter's output and stops scanning when it detects a continuous carrier. The filter then locks onto the precise frequency of that carrier and notches it out, tracking the interfering signal for any variations in tone until the interference disappears. Then the filter resumes scanning, searching out the next offensive carrier.

On-the-Air Testing

Setting up the MagicNotch is easy, and J•Com includes power and audio cables. The back of the MagicNotch has "audio in," "audio out," and 12V DC in jacks. Connect your rig's external speaker output to the "audio in" jack, connect your speaker to the "audio out" jack, connect 12V DC to the power jack, and you're in business. You can use any filtered power supply for the 12 volts (maximum current at full output is only 200 mA). Many HF rigs operate from 12 volts, and you may have an accessory power jack on your rig. Check your rig's owner's manual. I used a small 3 amp supply that I had sitting around.

The front of the MagicNotch has a 3-position slide switch, an LED, and a mini headphone jack. When you slide the switch to the center position, the MagicNotch is in standby mode (labeled "Bypass" on the panel). The LED will light green (if you've got it wired correctly). As you tune through the band, the LED will flicker to red and back to green. When a continuous carrier is detected, the LED will change to a steady red, indicating that the notch filter has locked onto the carrier. In the "Bypass" position, you will still hear the interference in your speaker. Sliding the switch to the "On" position will place the filter in the audio line, and the interfering signal will be filtered out.

To really get a taste of the effectiveness of the MagicNotch, leave it in the "Bypass" position and tune around for an SSB QSO that is being interfered with by someone tuning up. Switch the MagicNotch to the "On" position and the tuner-upper is gone, leaving only the SSB signal. No matter how weak the SSB signal is, or how strong the CW carrier is, the MagicNotch will eliminate the interference and leave the SSB signal intact.

Now, when a lid tries to tune up on top of your QSO, a simple flick of the switch and the lid is gone. If you leave the MagicNotch in the "On" position, you'll never even know the lid was there.

Be sure to switch the MagicNotch to "Bypass" or "Off" when you want to monitor CW. The filter may notch out what you're trying to copy!

MagicNotch Specifications

Notch depth	40 dB
Gain	0 dB
Active range	200–4000 Hz
Filter Q	10
Power output	2 watts (8Ω load)
Power required	10–14 VDC
standby	40 mA
full output	200 mA
Minimum signal for lock	20 mV P-P
Maximum signal	4 V P-P
Audio connectors	0.125" mono phone
Power connector	0.220" coaxial
Size	5.5" x 3" x 1.25"

Nice Touches

The MagicNotch is an example of a product that is designed to do a specific task, and it does that very well.

The short instruction manual is well written and informative. The inclusion of the power and audio cables in the purchase price is a courteous and convenient gesture that other companies would do well to imitate.

The front panel headphone jack is a mini-stereo jack that allows you to use the headphones from your portable stereo/tape player. If you've ever spent all day with a large set of headphones clamped to your head, you'll appreciate being able to use lightweight headphones for a change. Some might question the frequency response of headphones intended for music listening used for communications, but I like the more balanced tone of a stereo headphone.

In a hobby full of gadgets, it's nice to find one that is a useful addition to your shack. The MagicNotch is just such a gadget. I call it my "lid filter." 73

Apartment Antennas: A Challenge

How to cope with a less-than-ideal QTH.

by Stan Gibilisco W1GV

I recently moved into an apartment complex where outdoor antennas are not allowed. This predicament is not unfamiliar to radio hams and shortwave listeners. It does not have to mean a low-performance station, but it inevitably means that there must be some compromises. A full-size, 4-element, 40 meter yagi, and other such antennas, are out of the question.

Here are some of the schemes I have tried so far, and some ideas for future experimentation. I can always go back to my parents' house on the hill to work contests and DX, and this is the attitude I carried into the new apartment.

Survey the Layout

Whatever your particular situation, you will immediately see some obvious possibilities for antennas if you take the time to look things over.

My apartment is on the third floor of a three-story complex. My main motivation for choosing this location was noise: No one will be clomping around above me all day and all night. It turned out to be good from a ham radio standpoint, too. The ceiling is 30 feet above the ground. The building is old, and is therefore probably not of the solid concrete-and-steel Faraday-shield construction typical of newer high-rise complexes. There is a fire escape right outside the living room window, a formidable mass of metal that ought to make an excellent ground for a high-impedance antenna system.

The point is that any apartment will have some redeeming properties for radio communications. Well, almost any. Perhaps my friend who used to live in Arlington, Virginia, had just about the worst deal I have ever seen, a low floor in a jungle of tall buildings. Evidently hamming was not high on his list of priorities.

Any apartment living arrangement presents the danger of RFI and it is far better to put extra effort into the antenna system than to attempt to overcome a deficiency by running high power. I prefer not to get into wars with my neighbors. I'd just as soon have them never suspect I am a radio ham and never have any interference from me. With this in mind, I kept in mind the corollary to the antenna restriction: If you never get caught with an outdoor antenna, then, in effect, you don't have one as far as the management is concerned.

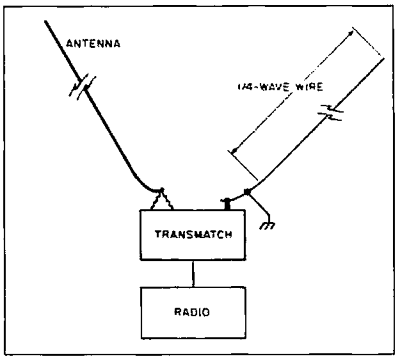


Figure 1. Installation of a ¼ wavelength "radial" wire as an RF ground. The wire should be as straight as possible, and the far end left free.

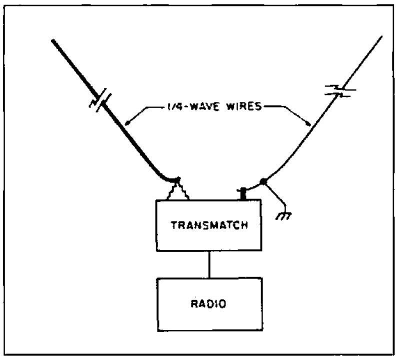

Figure 2. When a ¼-wave, end-fed wire antenna is used with a ¼-wave ground lead, the result is a center-fed dipole antenna. In this case the "radial" contributes to the radiation of the antenna system.

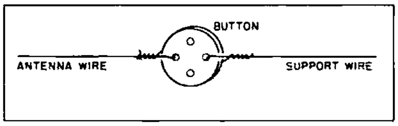

Figure 3. A button may be used as an insulator for "invisible," low-power antennas.

This last statement is not intended as an encouragement to break the rules of your lease. You do that at your own risk. If you try it and get into trouble, I shun all responsibility.

Establishing Ground

I cannot overemphasize the importance of obtaining a good ground for radio-frequency communication. A good direct-current (DC) ground is not necessarily a good radio-frequency (RF) ground.

The term "RF ground" is somewhat nebulous. A good ground at one frequency may be terrible at another frequency. The type of antenna being used makes a great difference.

If the ground loss resistance is given by R_L and the antenna input radiation resistance is given by R_R, then the efficiency of the ground system is given by:

$$Eff(\%) = 100 \bullet R_R/(R_R + R_L)$$

The higher R_R is, compared to R_L, the higher the efficiency of the ground system. End-fed antennas measuring an integral multiple of 1:2 wavelength tend to have very high values of R_R and are therefore best for use when the RF ground is marginal—and in an apartment situation, it almost always is marginal, at best.

You can get a good RF ground by installing a quarter-wavelength wire at the station transmatch or transmitter chassis, as shown in Figure 1. This will produce high current, and therefore low resistance, at the operating frequency, and also at odd integral multiples of this frequency. Such a "radial" ground wire will radiate to some extent, but this is minimal when the antenna feedpoint resistance is very high. If the antenna is a quarter-wave wire with a rather low feedpoint resistance, the arrangement will combine with the antenna to form a dipole having a feeder length of zero (Figure 2). This arrangement will still function quite well. For multiband operation, multiple "radials" can be installed, each cut to ¼ wavelength at the center of the desired band according to the equation:

$$L(feet) = 240/f(MHz)$$

where L is the length of the ground lead and f is the frequency. The far ends of these "radials" are left free, not connected to any object.

MFJ Enterprises, Inc., makes a tuner designed especially for resonating an RF ground. According to a *QST* review, this device works quite well.

The Transmatch

I have mentioned the use of a transmatch almost as if it were given that you have one. It ought to be; transmatches are indispensable

for apartment dwellers and any radio ham who operates portable very often. The added versatility is well worth the cost of the device.

The best transmatches allow for tuning random wires and balanced feeders. Most modern transmatches employ ferrite balun transformers to obtain tuning for balanced antenna systems. This is fine as long as the core does not saturate during transmission. Depending on the impedance at the feedpoint, the core may saturate at power levels much lower than that specified by the manufacturer for operation of the transmatch. I have actually cracked a ferrite balun core using 500 watts output when the transmatch specifications stated that it was usable up to 3 kW. This same transmatch became quite hot during operation using 500 watts output and an unbalanced ⅝-wave wire at 1.8 MHz. The choice of a transmatch is obviously important. In general, those with very large components will be better suited for high power (more than 200 watts output) than those with smaller components, even if the latter carry impressive specifications. Certain laws of nature will not yield to miniaturization technology—not until we have superconductor coils and cryogenic vacuum-variable capacitors!

The main advantage of a transmatch is that it allows practically any antenna to be resonated. You should choose the antenna with efficiency in mind, regardless of the availability of a tuner, but high-impedance antennas, the kind that work best with marginal grounds, generally require a tuner to produce an acceptable standing-wave ratio (SWR).

A Simple End-Fed Wire

Perhaps the simplest antenna is an end-fed wire, running directly to the output of the transmatch and cut so that it is an integral multiple of ½ wavelength on all of the desired transmitting bands. In amateur radio at high frequencies the bands are harmonically related, so if an antenna is cut to be ½ wavelength at 80 meters it will be close to an integral multiple thereof at 40, 30, 20, 15 and 10 meters.

Outdoor antennas are often not allowed, but a thin wire, three stories above the ground, is difficult to see. I recommend enameled copper wire of American wire gauge (AWG) No. 24 or smaller, down to AWG No. 30. The larger wires are physically stronger but more likely to be seen; the finer wires are more likely to break. Don't string such an antenna where it might cause problems for people if it breaks. Keep in mind, also, that if there is a frost, an "invisible" antenna may greet you some morning with an announcement to the world almost comparable to reveille.

The far end of a thin wire antenna may be tied to a button as an insulator, as shown in Figure 3. Allow plenty of slack for the wire to swing with the wind. A strong tree branch is all right for the far end of the antenna, but a solid, stable object is superior since it will not move in a wind. Avoid stringing the wire over or under utility wires. Table 1 gives good lengths for wires for various lowest amateur bands.

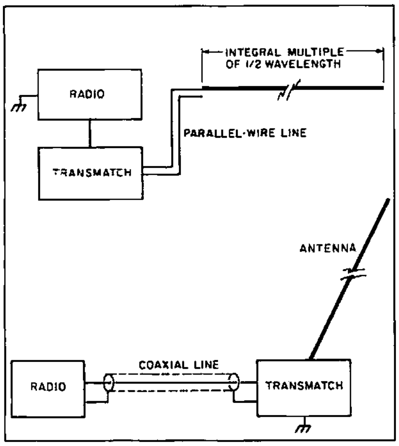

Figure 4. In drawing "a," a parallel-wire feedline is used with an end-fed wire that is very close to an integral multiple of ½ wavelength. In "b," the transmatch is located some distance from the transmitter, and the antenna is end-fed through the transmatch.

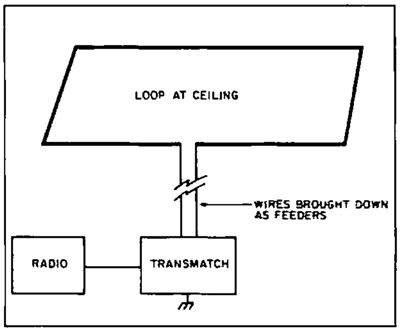

Figure 5. An indoor loop may be fed by bringing the wires down from the ceiling, parallel to each other, to the balanced output of the transmatch.

For shortwave listening the length is less critical, since antenna efficiency is not as important. Generally, a length of at least 50 feet will suffice, although longer wires are recommended for listening below the 160 meter (1.8 MHz) amateur band, and at longwave frequencies, length should be as great as can be managed.

The disadvantage of an end-fed wire is that the radiating portion of the antenna comes right down to the station. However, in an apartment situation where the landlord will not allow rooftop antennas, long feedlines are impractical anyway. If the station must be located away from the window where the antenna comes in, then a parallel-wire line may be used and the antenna connected to one end of this line. However, the antenna must be very close to an integral multiple of ½ wavelength to avoid line radiation (Figure 4a). Alternatively, you can run coaxial cable from the transmitter to the feedpoint, then connect the tuner to the antenna and RF ground at this remote point (Figure 4b). This is inconvenient when it comes to changing bands, but it is the best alternative in some cases. The RF ground must be connected and effective at the transmatch when this scheme is used.

An Indoor Loop

Simple end-fed wires may be connected for use indoors, although the lengths may vary somewhat when the wires are not straight. For indoor antennas, a balanced loop is probably better than an end-fed antenna.

Basically, the loop antenna always presents a balanced load at the input. This eliminates the need for a good RF ground and also gets rid of frequency sensitivity. The loop should be at least ½ wavelength, and preferably at least one wavelength, in circumference.

My apartment is quite large, and the ceiling is about 30 feet above ground level. An indoor loop, run around the entire apartment at the ceiling level, was an obvious choice. I installed this antenna almost before I got all the furniture in and the bed made up. I found stranded, insulated AWG No. 20 wire at a surplus shop for a few dollars. Hamfests are great places to get wire like this. I connected the loop to the balanced terminals of the antenna tuner, without regard to the overall length of the loop: I knew only that it was at least 100 feet in circumference, and close to a full wavelength at 7 MHz. I did the tuning on all bands, 80 through 10 meters, and logged the transmatch settings for future reference.

The loop was fed by bringing the end wires down parallel to each other, as shown in Figure 5.

Separate Receiving Antennas

Indoor antennas, and any antenna in a population-dense place like an apartment building, will pick up considerable man-made noise. The noise blanker on my FT-101EE is effective against much of this noise, but some broad-spiked noise is difficult to suppress with any noise blanker. In some cases a special receiving antenna may be needed.

A small loop with a tunable preamplifier is an asset in noisy places. The loop should be rotatable in both the vertical and horizontal planes, allowing you to find the noise null. It can be exasperating when there is more than one noise source and they keep alternating; the loop may need

Table 1. Lengths of wire antennas (end-fed) for half-wave operation at various amateur bands. The bands are indicated in meters, with the lowest frequency band first. Half-wave resonant frequencies are given in MHz, and represent the centers of the lowest bands.

Bands of Operation	Resonant Frequency	Wire Length Feet	Wire Length Meters
160, 80, 40, 30, 20, 15, 10	1.900	246	75.1
80, 40, 30, 20, 15, 10	3.750	125	38.0
40, 20, 15, 10	7.150	65	19.9
30, 15, 10	10.125	46	14.1
20, 10	14.175	33	10.1

frequent adjustment. The subject of receiving loops is complex and is beyond the scope of this article. However, Doug DeMaw W1FB has written numerous articles in *QST* about receiving loops.

Commercially-manufactured receiving loop antennas are available. Palomar Engineers manufactures one that has a preamplifier and a ferrite loopstick that can be rotated in both the vertical and horizontal planes.

A separate receiving antenna is, of course, necessary only for ham stations in which there is also a transmitter. When a separate antenna is used for receiving, precautions must be taken to ensure that the signal from the transmitter does not damage the receiver front end or the preamplifier. Some preamplifiers have protection built in. Some don't. Protection may not be necessary at low levels of transmitter power, but it is always a good idea.

That Gremlin: RFI

Radio-frequency interference (RFI) is so common nowadays that, unless you are running milliwatts or are extremely fortunate, you will encounter it in an apartment situation. There are video tape machines, low-cost hi-fi and television receivers, and all kinds of other devices that are susceptible to interference from amateur radio signals. It seems that the problem has multiplied in recent years because of two factors: the greater number of susceptible devices, and the general neglect of manufacturers when it comes to protection from strong electromagnetic fields.

The RFI problem takes a different, reversed form when consumer devices interfere with the radio amateur's communications. Home computers are notorious for this. Other devices, such as cordless telephones, can cause trouble as well. It seems that a double standard applies in the public mind for RFI: It's all right if the radio ham gets interfered with by a consumer device, but it's a cosmic catastrophe if it happens the other way around. It is not my place to say whether or not soap operas and video games are more important than radio communications of a hobby nature, but radio amateurs have to be prepared to face the facts.

In the event of a confrontation with neighbors, the American Radio Relay League, 225 Main Street, Newington CT 06111, (203) 666-1541, may be of assistance. They are familiar with legal cases that have occurred as a result of RFI.

My own attitude is that I won't operate if it interferes with some other person's activities. I don't consider myself that serious an operator. I'll reduce power or operate when nobody else is awake. But not everyone shares this tempered, retiring view. The most the ham can do is be certain that his transmitted signal is "clean"—free of harmonics or other defects in quality—and that he is running no more power than is necessary to carry out the given communications. This power issue is often overlooked: We hams tend to run more power than we need, most of the time. Apartment dwellers must keep constraints such as this in mind.

Many RFI problems can be cleared up by the installation of such things as line filters, better grounds, or different antenna systems. An indoor antenna is more likely to cause RFI than an outdoor one. There is some evidence to suggest that vertically-polarized antennas are more RFI-prone than horizontally-polarized antennas. A two-wire line must be kept in proper balance; a coaxial line must be free of "antenna currents" on the shield.

Further Ideas

The outdoor "invisible" end-fed wire and the indoor loop are the two antennas I have tried so far. Of course, there are other possibilities. A balanced "invisible" dipole, actually a shortened random V beam, is another scheme that might lend itself to my situation. This would be a set of two end-fed random wires, each of the same length, connected to opposite poles of the balanced transmatch output. Such an antenna would require no RF ground and would be balanced over a wide range of operating frequencies.

Perhaps the most interesting idea must wait until those long, cold winter nights, when the 1.8 MHz band comes to life. I find it hard to resist this band during those times. I figure if I'm not partying in Miami on those winter nights, the next best thing is a good cup of hot chocolate and an efficient antenna for 160 meters. I have used balloons and aluminum welding wire to make full-size "vertical" antennas of ¼ wavelength and longer on this band. Depending on the proximity of the utility lines, a scaled-down version of this idea might be used in an apartment *[Ed Note: Not recommended for apartment dwellers, it's best to try this in the wide-open spaces of the country. If you try this idea, make sure you are more than the length of your antenna wire away from any power lines, and don't try this on a windy night!]*. The balloon would have to be dark, so that it could not be easily seen at night, and it would have to be small enough to fit through the open window. Then there's the problem of getting the gas cylinder up three flights of stairs without provoking questions or getting a hernia. But, as the saying goes, when there's desire, there's no limit to what one can do. For a radio ham fond of the 1.8 MHz band, winters in the Upper Midwest have a way of cultivating desire. Let's see: a pound of that wire alloy 5356 with a 0.030-inch diameter is about 1,250 feet, so ¼ wave at 1.8 MHz, about 125 feet, would be only 0.1 pound, or 1.6 ounces. A 24-inch balloon would easily lift that, and ought to fit through the window with a little effort. Of course, I'd have to have the lights off so no one would see me climbing out onto the fire escape at midnight in below-zero weather with this two-foot balloon, but that's no problem. A little sign on the windowpane could remind me to switch off the lights before going out. . . 73

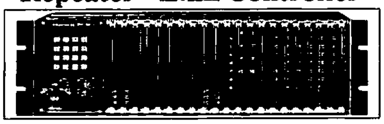
Repeater - Link Controller



RBC-700 Controller

The RBC-700 represents the latest generation of advanced repeater controllers. These series of controllers can connect up to 7 independent receivers and transmitters. 24 different configurations are available that supports up to 5 fully duplexed link radios, 4 independent remote base radios, and multiple repeaters simultaneously. Card-cage design allows expansion by simply adding cards and firmware. A true 7 position cross-point switch is utilized that allows each receiver / transmitter to independently connect to other Rx/Tx combinations as desired. Multiple independent Rx/Tx paths are supported.

Multiple Repeater control	Easy servicing
Up to 5 Duplexed Links	Intergrated Autopatch
Up to 4 different Remotes	+10v to +14v Supply

TEN-TEC PARAGON OWNERS

Upgrade your Paragon with the **Giehl Electronics Software Enhancement Kit.**

YOU GET THESE FEATURES:

- Band registers that store the last used frequency, mode, and filter for all HF ham bands 160 through 10 meters
- A 10 Minute ID reminder
- Single key band selection
- 5 different VFO tuning rates
- Dual VFO offsets and simultaneous Rx and Tx offsets
- Up and Down keys selectable between 1MHz/100kHz or 5kHz/10kHz
- Retention of last memory channel number
- Installs in 10 minutes with no soldering
- Many other enhancements

The kit includes the software chip and complete documentation for your manual. Cost is $72.00 plus $3.00 shipping and handling. Send check or money order to:

73 Review

by Dick Goodman WA3USG

The SR3 Simplex Repeater from Brainstorm Engineering

Versatile store-and-forward voice controller.

Brainstorm Engineering
3170 Beaudry Terrace
Glendale CA 91208
(818) 249-4383
Price Class: $330 with PL decoder installed; $230 without PL decoder.

The concept of a "simplex repeater" is quite simple. It is a voice store-and-forward device very similar to a packet digipeater. Additional hardware requirements are minimal—only one standard voice-grade radio and antenna is required for operation. The primary advantage to this type of repeater is in its simplicity. There are no duplexers, multiple antennas, external receivers, or auxiliary equipment needed. It can be installed in an automobile using an existing transceiver, driven to a high location, and put into operation immediately. It may even be used with a handie-talkie to provide portable repeater capabilities in a package considerably smaller than 1 cubic foot.

Sounds too good to be true, doesn't it? Well, it has a few disadvantages over a conventional repeater. Since it uses a single radio channel, it is a "half-duplex" device. The user keys his or her transceiver, speaks for a limited period of time, unkeys the transceiver, then hears the message repeated. The person that the user is communicating with would also hear this message and respond in the same manner. It's not really conducive to rag-chewing, but it is quite practical for applications where one or more people need to communicate but are out of range of each other. The simplex repeater can be centrally located, allowing everyone to communicate through it.

Photo A. The Brainstorm Engineering SR3 Simplex Repeater.

Until recently, simplex repeaters used either endless tape loops or standard cassette tapes as the voice storage media. While the user transmitted, the tape transport recorded the transmission. As long as the user had the transmitter keyed, the tape ran. When the transmitter was unkeyed, the transport went into a "rewind" mode, rewound the tape, and replayed the message. This caused a delay in repeating the original message, and it was a mechanically complex operation subject to problems. With the availability of inexpensive voice digitizing and storage devices, this inherent mechanical problem has been solved.

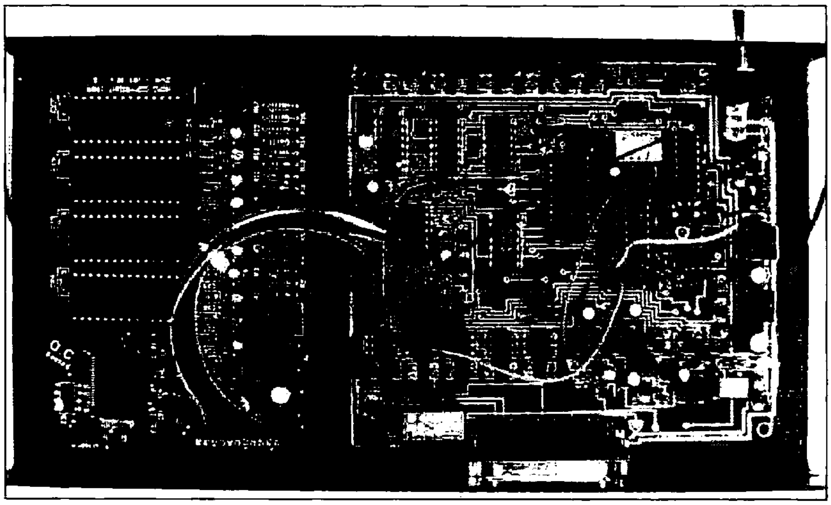

Photo B. Inside view of the SR3.

Enter the Brainstorm Engineering SR3 Simplex Repeater

The Brainstorm SR3 is packaged in a sturdy, all-metal case that you could almost drive a car over. Its dimensions are: 10.5" wide, 6" deep, and 1.75" high. It performs all the functions of a simplex repeater with none of the problems of the older, mechanical units. The power requirements are 11.6 to 15 VDC at approximately 200 mA. As well as functioning as a simplex repeater, it serves as a simple voice mailbox system, and a voice repeater IDer. All modes of operation can be controlled by DTMF tones.

The documentation that comes with the SR3 is excellent. It includes clear and concise specifications, operating instructions, and configuration data. The block schematics and circuit board layouts are high quality line drawings that are easy to read and will enable virtually anyone to interface the SR3 to a variety of radios.

Configuration, Setup and Operation

The front panel of the SR3 is simple and uncluttered. There are five "status" LEDs, and a power switch. All input and output to the SR3, including power, is via a DB-25 connector located on the rear panel. Brainstorm Engineering includes all connectors and cables necessary to get the SR3 up and running. Interfacing the SR3 to the radio is quite simple. Connections are made to the microphone audio input, the PTT input (the SR3 PTT line goes low at transmit), and the external speaker audio output. The SR3 has internal adjustment of both TX and RX audio levels. There are two versions of the SR3: the PL (Private Line) subaudible tone version, and the non-PL version. The unit reviewed here was the PL version, and I recommend it highly as it adds

considerably to the versatility of the unit.

As well as the connections to the radio identified above, the SR3 needs to know when a signal is being received by the radio connected to it. There are pins on the DB-25 interface connector that may be connected to any point in the radio that goes high (2–12 VDC) when a carrier is received. Many radios have "busy" LEDs that serve this purpose well. I used the "busy" LED on my Heathkit HW-2036 and it worked nicely. The problem with this is that the radio must be modified for this to work. Also, some of the newer rigs use an LCD "busy" indicator which may not have the correct voltage level for the SR3. If you have the PL version of the SR3, this is not a problem. Whenever the SR3 hears the correct PL tone from the user's radio it assumes that a carrier is present. The big advantages of this are that absolutely no modifications are required of the radio, and communication may take place on the SR3's frequency, without being repeated, by simply turning off the PL on the user's rig. The PL version will detect the presence of the carrier by either the voltage level or the PL method.

The SR3 is extremely reliable and easy to use. The three operating modes—"simplex repeater," "voice mailbox," and "voice repeater IDer"—can be enabled or disabled via DTMF input from the user. It should be noted at this point that only one mode may be used at a time. For example, if the SR3 is in the "simplex repeat" mode it cannot be a "voice IDer." The SR3 comes standard with memory for storage of 16 seconds of voice. A maximum of 64 seconds may be installed by adding additional SRAM chips.

The Simplex Repeater Mode

This is the mode that the SR3 defaults to after power-on reset. When the SR3 senses a carrier, it immediately goes into the "record" mode and stores the user's audio until the carrier drops. When the carrier is gone, the SR3 keys the transmitter and plays back the received audio. I found that after playing a bit with the RX and TX audio level adjustments, excellent audio quality could be obtained. I tried out the "voltage level" COR carrier detection technique in the shack and it seemed to work well. The PL carrier detection really shines, however. It worked quite reliably with all stations that tried it.

The Voice Mailbox Mode

This is a simple voice mailbox. It will store only one message at a time. If additional messages are entered, they will overwrite the original message. The mailbox mode may be entered via the proper DTMF code.

There are two ways to leave a message. In the first method, the user keys the transmitter, dictates the message and, without dropping the carrier, presses the correct DTMF key. The message is now stored and will be repeated any time the SR3 senses a carrier. The SR3 will not interrupt a QSO on frequency, but the message will be repeated each time a carrier is sensed and dropped.

In the second method, prior to dictating the message, the user keys the transmitter and enters the correct three-number DTMF code, states the message, and sends the correct two-digit DTMF code. This all must be done without unkeying the transmitter. Now the message will only be repeated upon receipt of the correct DTMF code from the recipient. This may sound complex, but it is relatively easy to master.

The Repeater IDer Mode

This is a simple but effective way to either voice-ID your conventional repeater, or to generate announcements of general interest. The SR3 contains a timer that may be set from about 10 seconds to 20 minutes. After loading a message or ID, the SR3 will output this message the first time the repeater is keyed. After this, the message will be disabled until the SR3's timer has reset. Upon completion of this reset, the message is enabled for transmission the next time the repeater is keyed. By sending the correct DTMF tone, the message may be generated at any time.

Other Features

The built-in DTMF decoder allows complete control of the SR3 remotely. Messages, IDs and voice mail may be entered and overwritten using the correct codes. The SR3 may also be taken completely off line via DTMF control. An additional feature is a DPDT relay option that can be user-installed. This lets you pick up or drop out a relay via DTMF control. Use the relay contacts for your own control purposes.

Other Uses

Tim Barefoot KA3ATH has been of great assistance in this review. He interfaced the SR3 into his home station. A number of guys in the Keystone VHF Club of York, Pennsylvania, played around with it. All three modes of the SR3 were exercised and worked well. Everyone was thoroughly fascinated with hearing their own voice being repeated back. The Keystone Club is in the process of putting up a 440 MHz/50 MHz linked repeater. We presently have the SR3 interfaced as a simplex repeater on the 6 meter side. It is interesting to drive around different areas of the county, store voice audio in the SR3, and play it back. It has told us a lot about the coverage that we expect to get from the repeater. We will probably try the SR3 on the 440 MHz side when we get it completely up and running.

I have experimented with sending SSTV audio into the SR3 on 2 meters with my Robot 1200. The audio back from it reproduced the original picture reasonably well. An SR3 placed in a central location would allow all members of a club to evaluate the operation of their rigs by allowing them to listen to their own signal coming back. Finally, an SR3 in your shack in the voice mailbox mode would allow you to leave a message for the XYL, even if she was not home at the time.

I found this device to be quite interesting and intriguing! There are many other uses for it, and one has to let his or her imagination set the limit. With the advent of inexpensive digital electronics, I hope that other products will be as innovative as the Brainstorm Engineering SR3 when they hit the market. ■

BARTER 'N' BUY

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Expedition News

A5 Bhutan. Jim VK9NS and Kirsti VK9NL are planning to operate from Bhutan, beginning around May 1. This will be the second operation for Jim, who signed A51JS last year.

US0UT. During February and March, Nick UB5UT was active from Lavrentiya with this special callsign. Lavrenliya is located just across the Bering Strait from the mainland of Alaska. For DXCC purposes, a contact with this station counts for the DXCC country of Asiatic R.S.F.S.R. (UA9/UA/0). QSL via Romeo Stepenenko, Box 812, Sofia 1000, Bulgaria.

UNSC8R1—Guyana. This is not a new type of antenna; it is the callsign of a new station operating from Guyana (8R1). The operator told K5OVC that this is the callsign typed on his license, and he is using it accordingly. It should probably be more like 8R1UNSC. QSL to Juan Larrabure, 42 Brickdam, Georgetown, Guyana.

Pirates. 3A0RA was a pirate. Don't waste your time or money sending a QSL to W4RA for a contact with him. Larry W4RA knows nothing about this station and is certainly not the QSL manager. 5X5GH, who also said to QSL via W4RA, is also believed to be bogus.

5A1DX was also a pirate; don't bother QSLing to W4BFQ for this one.

The station signing VU2TU/VU7 (Nicobar Islands?) appears to be a pirate. VU2RX is reported to have said that Indian regulations do not allow Indian stations to use a portable callsign. This station, if it had been legitimate, would have signed VU7TU.

XZ9A Burma. The persistent operation by XZ9A during February was the work of a pirate. The operator said to QSL via JA8IXM. JA8IXM knows nothing about this station.

QSL Notes

VK9MR and VK9LHI: Not via VK2WU. The manager for VK9MR (Mellish Reef) and VK9LHI (Lord Howe Island) is NOT the current license holder of the callsign VK2WU. The former VK2WU, who was the QSL manager for both stations, has moved, changed callsigns, etc., and evidently did not finish answering QSL card requests for either station. Does anyone know the whereabouts of the logs for these stations?

ET2A Ethiopia. There is a station on the air from Ethiopia! We've been getting bits and pieces of rumors during the past few months about a possible ET operation, but nothing worth printing. . . until February. The station is ET2A and the main operator is Jack W4IBB. Jack's wile and another operator named Scott may also operate the station from time to time. Jack has been trying to obtain a license for a year and a half!

There is a written license (which may be renewed), and by now it should have been forwarded to to the DXCC Desk. The station consists of a TS-140S transceiver and various antennas. Don't expect much, if any, CW activity from Jack, but Scott may give it a go. QSL via WB2WOW.

Publications for DXers

The ARRL has published a new book on DX. Mark AA2Z, ARRL Publications Manager, describes *The DXCC Companion: How To Work Your First 100 Countries*, by Jim Kearman KR1S, as: "Intended for new DXers. . .it covers the sport of DXing from making the first DX contact to applying for the DX Century Club (DXCC) award. Everything the beginner needs to know about antennas, propagation, working 'split,' sending QSLs, and working DX on nets and lists, is presented in a bright, humorous style."

KR1S's publication doesn't cover everything, but it is a fine publication, and it certainly contains most of the information the beginning DXer needs. It's informative, easy to read, and certainly a worthy addition to any new DXer's library.

You can order *The DXCC Companion*, a 129-page soft cover book, from the ARRL, 225 Main Street, Newington CT 06111. The cost is $6.00 (plus $2.50 for postage and handling; $3.50 for UPS).

A booklet, "Russian Phrases for Amateur Radio," is available from Len Traubman W6HJK, 1448 Cedarwood Drive, San Mateo CA 94403. The cost of this booklet is $5. A 90-minute cassette tape is available for $6.

Special Prefixes

1H0, 1C4, 1P1, etc. The "one" prefixes are unassigned, but several callsigns with the "one" prefix have been adopted for use by stations operating from the DXCC countries of the Spratly Islands (1S) and the Sovereign Military.

Order of Malta (1A0KM). "One" prefixes have also been used on a regular basis by American operators when on IOTA expeditions. For example: NE8Z/1C4 and K1RH/1H0 from one of the islands in the South Carolina Group (IOTA designator NA-110) and several Texans have used the 1P1 prefix from Pelican Island (Galveston, Texas). The use of the self-assigned "one" prefixes by U.S. operators is not illegal.

7S3OWG Olympic Winter Games 1998. The special callsign 7S3OWG will be used until June 15 by members of the Jentlands ARC (SK3JR) to promote Ostersund (Sweden's candidate for the 1998 Olympic Winter Games). QSL via SM3CVM. 73

ATV in Space

When the STS-37 shuttle mission blasts off this April 4th, it'll be the second time an ATV receiver has been put into space. The first was the 1265 MHz receiver on the Webersat microsat. The next step? How about an ATV *transmitter* in space?

Project Excelsus

Students from Southeastern Community College in Whiteville, North Carolina, plan to launch their own space mission sometime in mid-May. Instructors Ben Frink and David Couvillon KC4WDW, along with Simms Spears, have put together a team of electronics and physics students who are busily assembling a very unique rocket/balloon (Rockoon) system.

The Rockoon

The students' ultimate goal is to launch a live *color* camcorder and an ATV transmitter to an altitude in excess of 50 miles (the beginning of space!). To accomplish this they are building a 10-foot long rocket (6 inches in diameter) which will carry a color camcorder and a PC Electronics KPA5-RC 1 watt ATV transmitter (439.25 MHz). A second transmitter on 1255 MHz FM TV (T.D. Systems) will send back pictures from a B/W camera. Even though they will be using a large Vulcan "M" size rocket motor, they could only reach a maximum height of a few thousand feet if launched from the ground. However, the plan is to fly the rocket up to 100,000 feet attached to a large plastic balloon (RAVEN model 52k). Since 100,000 feet is above most of the atmosphere, igniting their rocket from this point could send it up over 350,000 feet high.

Many government Rockoon flights have been flown to study the upper atmosphere. Some of these have made it well over 100 miles up.

The Rockoon consists of two separate packages, the rocket ATV system and the launch control platform. Telemetry from the platform is relayed down to mission control via a packet link designed by PacComm. The fire command is issued via this link which activates a special ignitor circuit. In addition, a third ATV camera and transmitter on 426.25 MHz will be located on the platform which will allow us all to monitor the rocket and watch the liftoff! There will be packet telemetry on 2m FM from the rocket as well as the launch platform. The final telemetry frequencies will be announced a few weeks before the flight.

Since the rocket won't achieve anywhere near orbital velocity, it will come back to earth as soon as it hits the maximum altitude. After ignition, the whole flight into space should only take a few minutes.

The Rockoon will be launched from the North Carolina shoreline and should drift about 50 miles out to sea before the rocket is fired. That way the rocket will return for a splashdown in the Atlantic. Several chase boats will be on hand to attempt a recovery.

Go Along for the Ride

Anyone within 400 miles of the launchsite should be able to receive the balloon transmission and watch the launch of the rocket. If the rocket makes it up to 50 to 100 miles, you may be able to watch spectacular views of space from over 700 miles away! At any rate, it ought to be quite a ride! For those of you using a *cable-ready* VCR or TV, you can tune in the rocket ATV transmitter on cable channel 60 and the control/ignitor camera on cable channel 58 (use a good vertically polarized 70 cm antenna for best results). An HF net will convene before and during the flight on 7.155 MHz with launch updates. It will also collect reception reports.

High Flying ATV at SCC

The Rockoon flight is the culmination of several

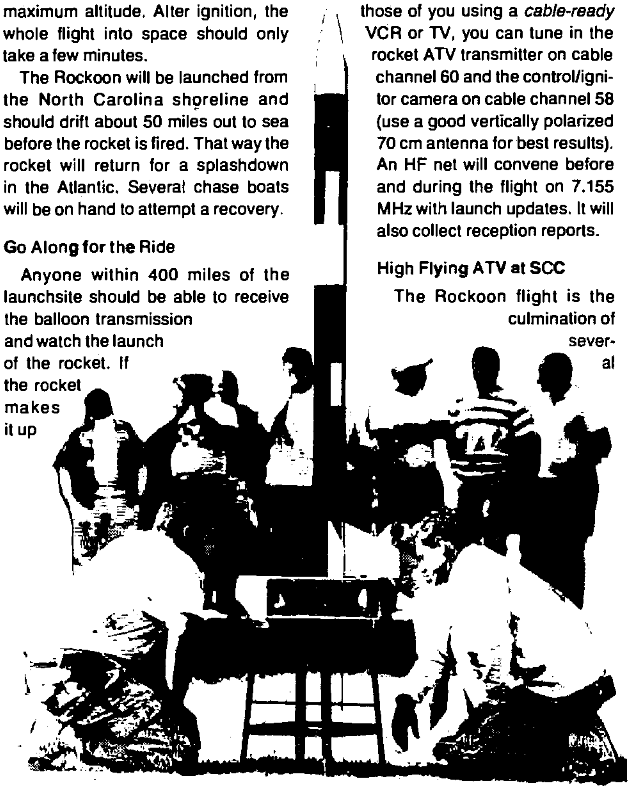

Photo A. The first SCC rocket ATV flight.

Photo B. A few members of the launch team holding the first balloon payload. From l ro r: Simms Spears, David Couvillon KC4WDW, Ben Frink, Bob Rau N8IYD and Bill Brown WB8ELK.

west of the ocean. Although local Wilmington, North Carolina, radio club members gave it their best shot, it was nearly impossible to get any signal through the dense pine forests in the area. Fortunately, two days later, a local resident found the payload lying in a ditch on the side of a small road.

The SCC group hope that these ATV experiments will inspire other schools to develop projects of their own. It's a great way to learn electronics while doing something new and exciting.

Launch Info

Update . . . The cross-country manned ATV balloon flight covered in

Dayton HAM TV Activities

Plenty of ATV activities can be found this year at the Dayton Hamvention. Check out the Friday evening (7:30 p.m.–midnight) annual ATV PARTY at the Holiday Inn North (just off exit 57-B on Interstate 75). Since over 150 ATVers attended last year's party, this year it will be held in the Grand Ballroom (seats 300). Lots of great speakers, demos and, of course, ATVers from around the world. Quite a contingent from the BATC (British Amateur Television Club) plan to attend this year.

The ATV Forum will once again be

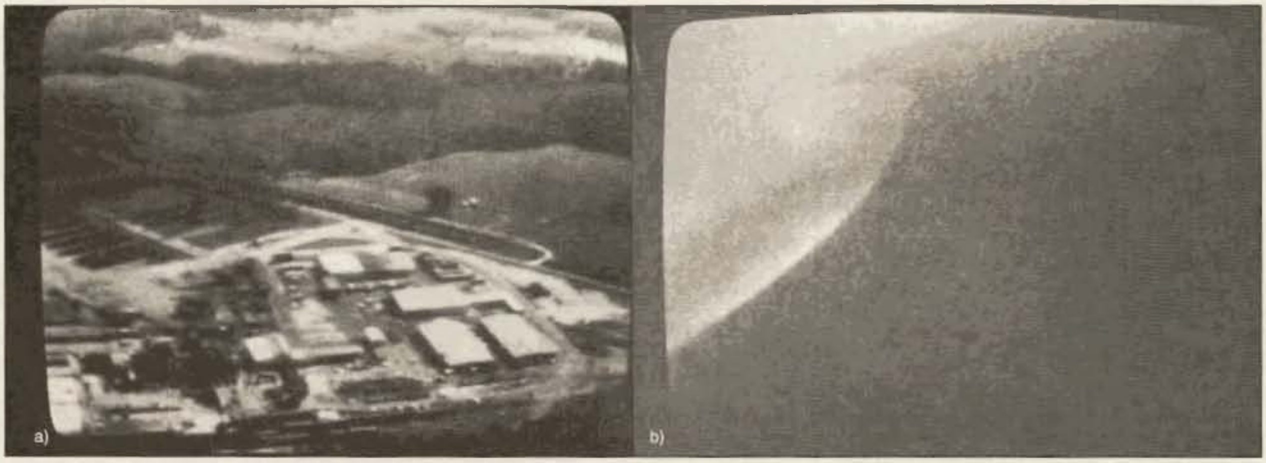

Photo C. Downlink video from the live camera payload. (a) the Georgia Pacific plant from 2000 feet. (b) 200 miles of the North and South Carolina coastline as seen from 65,000 feet.

airborn experiments that students at Southeastern Community College have performed. Their first flight consisted of a 4-foot model rocket with an HVM-322 camera and a TV transmitter which the students designed in their electronic engineering techology class. This flight was launched last May from the campus parking lot up to about 800 feet. When the camera popped out of the fuselage, you could see the crowd of onlookers getting closer and closer as the package parachuted back down. It was great to see the smiling face of the lucky student who caught it before it hit the ground!

The class became inspired by their initial success and invited Bob Rau (rocketeer) and me (balloonatic) down to help them launch their next payload on a high-altitude balloon. Just after noon on October 23, their live camera ATV payload was launched from the SCC campus attached to a 5-foot weather balloon. The class gathered around the ATV receive station at mission control (the electronics lab), fascinated by the spectacular views of the North and South Carolina countryside coming down from the balloon system. At 65,000 feet nearly 200 miles of the Atlantic coastline could be seen. Thanks to the efforts of Hap Griffin WA4UMU, visitors to the ATV booth at the Sumter, South Carolina, hamfest were watching as well. In addition, Fred Tuck WD4KTI and Don Fortner K4SAO had good reception from Inman, South Carolina (200 miles). One of the most amazing reception reports came from Ken Gallagher W3DFS in Adelphi, Maryland (350 miles away) who reported a completely snow-free P5 signal for about 10 minutes!

After the balloon burst, the package parachuted down to land just 8 miles

last March's column has been postponed until September. Look for further information and updates about this flight and Project Excelsus via AMSAT bulletins (both the nets and packet BBSs) as well as the Tuesday night ATV net on 3.871 MHz (8 p.m. Eastern time).

chaired by Tom O'Hara W6ORG at O'Hare arena on Saturday afternoon. Look for talks by Tom W6ORG, Carole Perry WB2MGP, Dave Baxter W5KPZ and myself.

While at Dayton, listen in to the action on either 144.34 MHz or 147.45 MHz. SEE you all there! 73

An Invitation to 4U1UN

Most of us would agree that any 8th grader should be able to speak intelligently about the United Nations, its background, and its role in the world today. Imagine my surprise at learning that only 20% of my 400 students in the 6th, 7th, and 8th grades could even identify the world famous profile of the UN Building at 42nd Street in New York City! My incredulity grew as I discovered that most of them didn't realize that we, in Staten Island, were within 45 minutes of the UN Complex.

You can hardly open a newspaper or listen to a TV news broadcast without some visual representation of the UN in the background. The world crisis centering around the Persian Gulf, and the recent role of the General Assembly, should have prompted provocative discussions in every school in the country. It is appalling to think that so many youngsters have disfranchised themselves intellectually from discussions or opinions about world events. The responsible adults among us should point out that it's their future hanging in the balance, too, and that they have an obligation to be well-informed about the decisions that world leaders are making.

We often get involved in discussions on current events as a direct result of contacts we make on the radio to different parts of the world. The teacher of an amateur radio course can easily bring in topics from other studies to the classroom. I was especially delighted, therefore, when I received an invitation to visit the United Nations amateur radio station, 4U1UN. This would be a great opportunity to bring information about this world body back into the classroom in a meaningful and exciting way.

I shared my feelings of excitement with the children. Suddenly, students were telling me what they'd heard about the UN on the news on TV, and they began bringing in newspaper articles about the General Assembly and the Security Council.

On Tour at the United Nations

When the big day arrived, I was given a list of questions prepared by the children in their social studies classes. Their teachers were delighted with the interest, and it was gratifying to me to be part of a team effort in education.

Upon my arrival at the UN, I was met by David Rosen K2GM, the station manager of 4U1UN. David was my gracious host for the day. During a wonderful lunch at the UN restaurant, we spoke about the background and history of the UN.

The UN is an international organization of sovereign nations, established to serve the cause of peace. According to its Charter, the UN attempts to do this through political action, such as mediation or prevention of conflicts among nations, and promotion of higher living standards through economic and social action. Its purpose is to develop friendly relations and cooperation among nations, and to serve as a center for harmonizing international action.

Since 1941, the UN has had several different sites. In 1946, the General Assembly accepted $8,500,000 from the American philanthropist John D. Rockefeller, Jr., to purchase a 16-acre site bordering the East River between 42nd and 48th Streets in Manhattan. Later the site was granted extraterritoriality status under the Headquarters Agreement concluded between the UN and the U.S. on June 26, 1947. Plans for the famous UN Complex were drawn up under the guidance of American architect Wallace Harrison, and unanimously adopted by the General Assembly in November 1947. The cornerstone was laid on UN Day, October 24, 1949, and work was completed by the middle of 1952.

The four main buildings are the General Assembly Hall, the Conference Building, the Dag Hammarskjold Library, and the Secretariat Building, which houses the amateur radio station 4U1UN.

In 1946, the UN adopted its official emblem, a map of the world seen from the North Pole, surrounded by two wreaths of olive branches. The UN flag, adopted in 1947, displays this emblem in white, centered on a light blue background.

Station 4U1UN

After an extremely informative tour of the complex, we spent several hours at 4U1UN. UN staff from all over the world, such as Panama, Sri Lanka, and Poland, comprise the UN Amateur Radio Club, of which Raymond East KB2BKO is president.

In order for the station to assist more efficiently, a special group of volunteers has been organized. The group consists of both amateurs and nonamateurs from the UN staff. Since 1986, 4U1UN and this support group have participated in 11 disaster operations.

Most importantly, the group has expanded to include a growing number of amateur stations outside of Headquarters who work closely with 4U1UN during crises. Most of these stations have been prominently involved with emergency activities in the past; they include WA1KKP, VP2MO, NP2CM, W8CZN, OA4OS, VS6VO, W9ARV, and K2EWB. Many other stations have recently joined the activity.

David emphasized that the Radio Readiness Group is entirely an amateur radio undertaking, and that stations interested in assisting 4U1UN when the normal channels of communications have been severed, are welcome to call in.

During disasters, when amateur communications are required, the net will meet on specified frequencies. The principal frequency is 14.268 MHz, with 14.168 as an alternate (traffic is also handled on other alternate frequencies as specified at the time). Other frequencies are 3768/3868/7068/7268/21368/28468.

During disasters, 4U1UN has been in liaison with relief agencies and other official entities. One such agency is UNDRO. "The United Nations Disaster Relief Organization" acts as a coordinator in the provision of aid to stricken areas. During emergency periods, 4U1UN has furnished UNDRO with post-event information about catastrophes. Situations involving hurricanes, volcanoes, and earthquakes are all helped by the rapid relaying of information by the amateur community.

Between the UN Headquarters-based Radio Readiness Group, with all of their area and language expertise, and the dedicated efforts of the Radio Readiness Group with the assistance of amateurs worldwide, it is hoped that 4U1UN and the Radio Readiness Group can make a difference.

David offered these priorities:

1. To address the emergency requirements in the disaster area as it pertains to the preservation of life.

2. To determine in a precise manner the extent of damages and needs—e.g., medicine, food, and shelter.

3. To optimize activities to be of the most value to the stricken area requires organizing the Headquarters and on-the-air group so that both elements may efficiently respond.

4. To efficiently expedite health and welfare traffic.

Members of the 4U1UN station feel that their amateur radio efforts meet the principles of the founding countries of the UN. It embodies what the nations of the world expected of the UN when they founded it.

They hasten to add that emergency support activities are also prioritized by all the amateur radio service, and they acknowledge the good work other emergency nets have done.

David pointed out that Resolution No. 640: Relating to the International Use of Radiocommunications in the Event of Natural Disasters, in Frequency Bands Allocated to the Amateur Service (WARC 1979) has now been incorporated into the amateur regulations of several telecommunication administrations.

On the roof, there is a wonderful array of antennas, including a Hy-Gain TH4, a Cushcraft 103CD, a Create CL 10DX 6-element 10 meter beam, dipoles for 40 and 80 meters, and a DX-88 7-band 10-80 vertical. A ruggedized Telrex 20M536 5-element, 20 meter beam is on hand and awaits installation. At the station, which I had the pleasure of working that day, is a Kenwood TS-940S and a Kenwood TL922A amplifier. David said their objectives are to install equipment sufficient to allow 4U1UN to operate on several bands simultaneously.

My visit to the UN was a personal treat for me, and also provided the opportunity to bring world events into the classroom through amateur radio. Peace through communications should be a goal for us all.

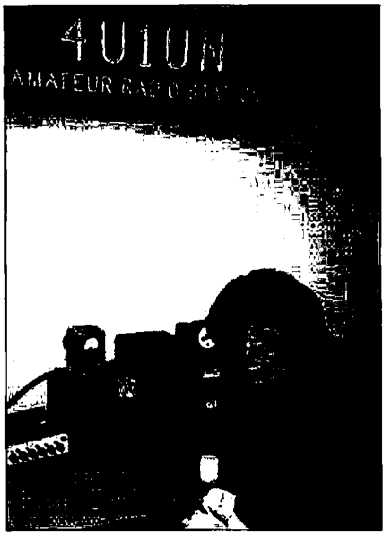

Photo A. Carole Perry WB2MGP, enjoying working 4U1UN.

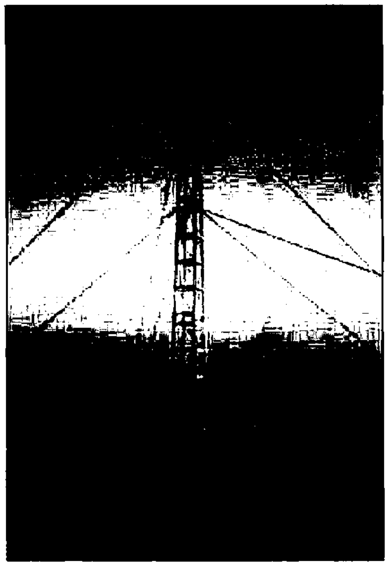

Photo B. David Rosen K2GM, station manager of 4U1UN, stands beneath the 4-element yagi on the UN building's roof.

Amateur Radio Via Satellite

Andy MacAllister WA5ZIB
14714 Knightsway Drive
Houston TX 77083

RS-14

RS-14 is up and active. It's hard to believe a 200 mW satellite beacon can be loud enough to be detected on any 2 meter antenna with almost any 2 meter receiver. Launched on January 29 of this year, RS-14, also known as RADIO-M1, RUDAK-2, or, as I intend to refer to it, AMSAT-OSCAR-21, has been sending CW telemetry on 145.822 MHz since February. The German-made digital experiment has also been energized for tests, and the linear transponders should be active by the time this column is printed.

In early 1989 Leonid Labutin UA3CR met with Hans Peter Kuhlen DK1YQ and other members of AMSAT-DL (West Germany) to propose a joint effort in the design and construction of an amateur radio satellite. Leo represented the AMSAT-U-ORBITA group and the Moscow Adventure Club, both of the U.S.S.R.

The groups agreed to work together on the program, and to design and build their portions of the satellite in time for a scheduled launch only six months away. The electronics would become a physical part of a Soviet geological research satellite called GEOS.

The Soviet group AMSAT-U-ORBITA worked primarily on the linear transponders and associated telemetry systems. They named their part of the system RADIO-M1. The "M" represents the cities involved in the program: Molodechno, Minsk, Moscow and Munich.

The Soviet's CW telemetry comes down at 20 words per minute, and you can hear it on any portable, home, or mobile 2 meter rig capable of CW/SSB reception. In between the eight groups of four digits each, the satellite identifies itself as RS-14. From home stations, the only obvious way to tell that the signal is not from a nearby transmitter is to listen to the Doppler shift on the signal's frequency as the satellite passes overhead. See Table 1 for frequency data. This is an updated version of the chart presented in the July 1990 "Hamsats."

The German contingent built a new version of their RUDAK experiment. RUDAK is a German acronym for "Regenerative Umsetzer fur Digitale Amateurfunk Kommunikation," or "Regenerative Transponder for Digital Amateur Radio Communications." The prototype RUDAK system worked for over two years from the top of a water tower in Ismaning, near Munich, Germany. The first flight-ready RUDAK system was a part of AMSAT-OSCAR-13, but it had minor wiring problems that had a disastrous impact. The experiment was never completely activated.

RUDAK is a complex packet store-and-forward system capable of input and output via many modes and data speeds. The original system was designed for high elliptical orbits where the satellite is in the sky for long periods. It was designed to rely on real-time digital communications (digipeating) with less emphasis on store-and-forward techniques.

RUDAK-2 on A-O-21 is in a low orbit, similar to the microsats. It is available several times a day, but only for short periods. This new version of RUDAK is built for bulletin-board features and other experiments that lend themselves to short access periods with much less emphasis on the digipeating capabilities.

Many signal types could be heard on the RUDAK-2 downlink frequency during initial tests from space. On February 25, stations around the world were surprised to hear speech on the RUDAK-2 output of 145.983 MHz. In a clear voice, with a slight touch of European accent, RUDAK announced, "I'm completely operational and all my circuits are functioning perfectly." This message repeated continuously for several orbits. On other occasions, very-high-speed data could be heard. It sounds like hissing over a span of several kHz.

The RUDAK system supports FSK (frequency shift keying), BPSK (biphase shift keying), RSM (rectangular spectrum modulation) and DSP (digital signal processing) operation. The DSP system works with any input or output for which programs have been created and activated in the spacecraft computer. This includes digital rates to 25K

Table 1. RADIO-M1/RUDAK-2 Data Sheet

Orbit Configuration

Polar circular orbit with average height 980 km (610 miles), inclination 83 degrees, period 104 minutes. Attached to GEOS, a Soviet geological research satellite. Launched in late January 1991 (from AMSAT-DL and AMSAT-U).

Frequency Guide

	Linear Transponder 1	Linear Transponder 2
Mode B Uplink	435.102–435.022	435.123–435.043
Mode B Downlink	145.852–145.932	145.866–145.946
CW Beacons	145.822	145.948
PSK Beacons	145.952 (1200 bps)	145.838 (1200 bps), 145.800 (1100 bps)

Regenerative Transponder RUDAK-2

Uplink	RX-1	RX-2	RX-3a	RX-3b	RX-4	Unit
Frequency	435.016	435.155	435.193	435.193	435.041	MHz
Speed	1200	2400	4800	9600	DSP	bps
Modulation	FSK	BPSK	RSM	RSM	any	
Coding	NRZIC Bi−Ø−M	Bi−Ø−S Bi−Ø−M	NRZIC NRZ-S+scrambler	NRZI	I+Q	

Downlink 145.983 MHz with 3 Watts typical (10W optional)

Mode 1: 1200 bps, BPSK, NRZI (NRZ-S) (like FO-20)
Mode 2: 400 bps, BPSK, Bi−Ø−S (like OSCAR-13 beacon)
Mode 3: 2400 bps, BPSK, Bi−Ø−S (planned for OSCAR-13)
Mode 4: 4800 bps, RSM, NRZIC (Bi−Ø−M)
Mode 5: 9600 bps, RSM, NRZI (NRZ-S) + Scrambler
Mode 6: CW keying (only for special events)
Mode 7: FSK (F1 or F2B), i.e. RTTY, SSTV, FAX, etc.
Mode 8: FM modulated by D/A signals from DSP (speech)

Technical Data

DC Power
Total system: 40W maximum
RUDAK-2 power consumption: 14V @ 350 mA (max) = 4.9W
Standby: 80 mA (RUDAK without power amplifier)
RF Output Power
CW Beacons (L/H): 0.2/0.4W
Digital Beacons (1200 bps/1100 bps): 0.4/2.0W
Transponders: 10W maximum
RUDAK-2 (L/H): 2/10W (3W typical)

Table 2. Radio-M1/RUDAK-2 PSK
Telemetry decoding information.
Digital-Telemetry of "RADIO-M1"
by AMSAT-U (RC2CA/UA3CR)
and AMSAT-DL (DG2CV/DB2OS)

Digital telemetry consists of 30 parameters + 2 constants. To receive the digital telemetry, you must use an FM receiver, a modem, a de-scrambler, and a personal computer.

RPC—Rudak Power Conditioner

bps, voice, and other modes not yet invented.

The linear transponders were not activated for use early in the satellite's life, but with several watts available for transponder activity, A-O-21 promises to be extremely easy to work. The transponders, configured in Mode B, are inverting. A 70cm lower-sideband uplink signal is retransmitted on upper-sideband. Similarly, a signal sent in the lower portion of the uplink band will be heard high in the 2 meter downlink span. Omnidirectional antennas will be sufficient for those wishing to use the satellite.

Decoding A-O-21 telemetry provides insight into the satellite's systems. While the equations for the CW data have not yet been released, the digital telemetry can be deciphered with data from Table 2. The 1200 bps (bits per second) PSK beacons can be translated by PSK/packet systems capable of receiving Fuji-OSCAR-20's digital mode or the microsat downlink signals.

The 1100 bps transmissions are not as easy. Although this signaling rate is a standard in the Soviet Union, it is nonexistent in the U.S. A DSP (digital signal processing) device with a modem program for 1100 bps PSK is the best alternative.

RS-12/13

On February 5, 1991, one week after the launch of RS-14/A-O-21, Cosmos 2123 went to orbit. It is a replacement for Cosmos 1655 which has been operational since May 30, 1985. The new Cosmos is a civilian navigation satellite and incorporates RS-12/13 into the main power bus. The older satellite did not require replacement as early as previously anticipated, so launch was delayed for over a year.

Table 3 shows an updated version of the amateur radio frequency chart that originally appeared in the September 1989 "Hamsats." Like RS-10/11, RS-12/13 has three main modes and associated ROBOT autotransponders. Frequency bands have been offset to avoid interference with RS-10/11, but otherwise the new system is identical.

Table 3. RS-12/13 Frequency and Data Sheet

Orbit Configuration

Polar circular orbit with average height 980 km (610 miles), inclination 83 degrees, period 104 minutes. Attached to Cosmos 2123, a Soviet navigational satellite (NAVSAT). Launched in February 1991 from Soviet command station RS3A.

Transponder TX	8W	8W

During the first few days of life in orbit, RS-12 and RS-13 systems were checked for proper operation. Tests were going well until the Cosmos 2123 150 MHz transmitter began interfering with the RS-12 2 meter receiver. Digital signals heard within the RS-12 10 meter downlink were obviously not of an amateur origin. Efforts have been underway by command stations to circumvent this problem. If the satellite's 2 meter receive predicament continues, RS-13 may be activated, or Modes K (15 meters up and 10 meters down) or T (15 meters up and 2 meters down) on RS-12 may be turned on instead.

Mode A operation requires an uplink signal, either CW or sideband, within the passband limits on 2 meters. Ten watts to a home station omnidirectional antenna does the job on most passes. A 10 meter receiver with a MOSFET preamp and dipole will work for the downlink.

The 10 meter downlink resides just above 29.4 MHz. Interference from terrestrial FM stations is very common in this portion of the band. Many hams are not aware of the internationally accepted satellite downlink band limits of 29.3 to 29.51 MHz. FM receivers can barely detect the presence of the weak sideband and CW signals from the satellites. An uninformed FM operator with a strong signal can wipe out several satellite conversations and not even notice that a serious problem exists. The ARRL "Operating Manual" clearly defines the 10 meter band plan with extracts from the ITU (International Telecommunications Union) Radio Regulations Table of Frequency Allocations.

Mode K with its 15 meter uplink and 10 meter downlink is a mode where many newcomers make their first satellite contact. Although it is difficult to avoid interference between a 21 MHz transmitter and a 29 MHz receiver at a home station, it is possible. Many have done it. Transmit and receive antennas must be kept segregated to avoid receiver overload. Coax cables should be of good quality and kept apart. Finally, transmitter power on the 15 meter uplink should be only enough to make contact through the transponder. There is no band plan for 15 meter satellite operation. When calling "CQ," specify "satellite" or "RS."

Interference between the 15 meter transmitter and 2 meter receiver is rarely a problem for Mode T activity. The downlink signals are easy to copy, but there is a problem with this mode for U.S. amateurs. The transponder limits on RS-10/11 allowed Novice class operation, but RS-12/13 does not. Only Advanced and Extra class hams can use Mode T via RS-12/13. Those with an Extra class license can use sideband or CW anywhere within the transponders, but Advanced class hams must avoid operation below 21.225 MHz. Consider upgrading!

Even with license limitations, RS-12/13 offers exciting satellite communications. Together with A-O-21, the scope of amateur satellite activity has been dramatically increased with these new resources launched from the Soviet Union.

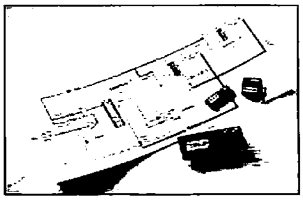
NEW PRODUCTS

Compiled by Hope Currier



ISD

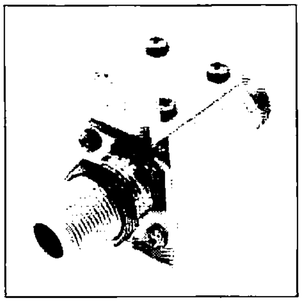
ISD has introduced the world's first implementation of non-volatile analog storage on a chip. The ISD1016, a single-chip voice messaging system, offers up to 16 seconds of telephone-grade voice recording and playback. With the addition of a microphone, speaker and just a couple of resistors and capacitors, you have an audio recorder on a chip! Applications can range from simple repeater IDs to voice mailbox systems. Multiple ICs can be cascaded for additional storage time. Twelve-second and 20-second versions are available as well (ISD1012 and ISD1020). The ISD1016 represents an exceptionally tiny solution with a miniscule energy budget, true zero-power nonvolatile storage array and extremely easy-to-use features.

For prices and more information, contact *Information Storage Devices, Inc., 2841 Junction Avenue, Suite 204, San Jose CA 95134; (800) 825-4473, (408) 428-1400, FAX (408) 428-1422.* Or Circle Reader Service No. 201.

POLYPHASER

PolyPhaser Corporation has added a new series of Nuclear Electro-Magnetic Pulse (NEMP) lightning suppressors to their popular line of coax protectors. The IS-NEMP series has threaded type "N" connectors standard on all equipment port interfaces. They handle up to a maximum surge of 50,000 amps with a $\leq$ 1.25 ns turn-on time, and 330 VDC voltage. They also have multi-strike capabilities, $\leq$ 1.1:1 VSWR, $\leq$ 0.1 dB IL, and throughput energy of $\leq$ 30μ Joules (based on 1 kV/ns waveform).

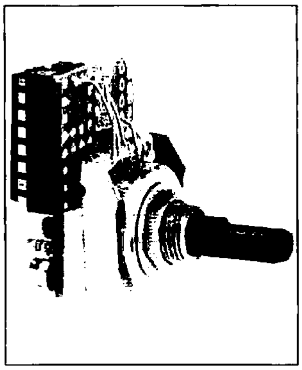
For prices and more information, contact *PolyPhaser Corporation, P.O. Box 9000, Minden NV 89423-9000; (800) 325-7170 or (702) 782-2511.* Or circle Reader Service No. 202.



COMMUNICATIONS SPECIALISTS

Communications Specialists is offering a miniature multi-tone encoder that permits selection of a discrete CTCSS or burst tone from a custom 12 (Model SS-12) or 16 (Model SS-16) tone memory. The tone is activated by a rotary encoder switch mounted on the board. In place of the usual DIP switch found on the old SS-32P encoder, these new boards have a 12- or 16-pole rotary encoder switch mounted on the bottom of the board. Up to 12 or 16 tones of your choice are programmed into the EEPROM before shipment, and can be changed later at no charge. The small size (1.3" H x 0.9" W x 0.73" D) allows for panel-mount installation in most base stations and many mobile radios.

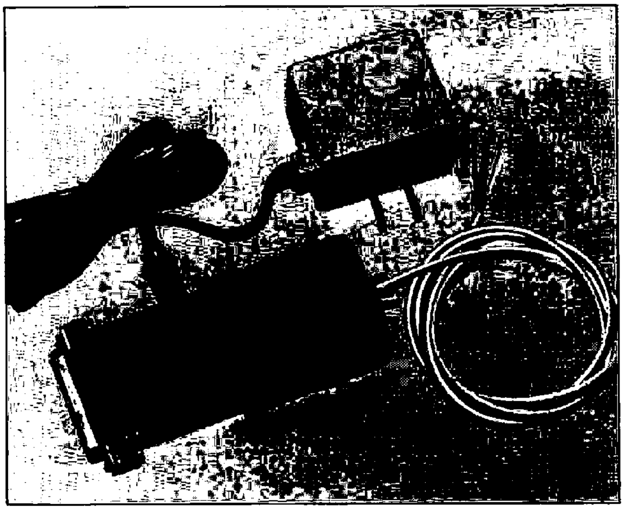
The SS-12 and SS-16 are priced at $39.95 each. Contact *Communications Specialists, Inc., 426 West Taft Avenue, Orange CA 92665-4296; (800) 854-0547, (714) 998-3021, FAX (714) 974-3420.* Or circle Reader Service No. 207.



EDWARD OROS

Edward Oros has released a conversion kit for the Uniden HR2600 and 2510 10m band radios, allowing them to transmit on 12m, making them dual-banders. The "Plus 12" conversion kit is easy to assemble and install—no drilling required! The total conversion time is less than one hour. All required parts and instructions are supplied with the kit.

The kit sells for $49.95, plus 6% sales tax for PA residents. Group discounts are available. Contact *Edward Oros, 2629 Sapling Dr., Allison Park PA 15101.* Or circle Reader Service No. 203.



DELTA RESEARCH

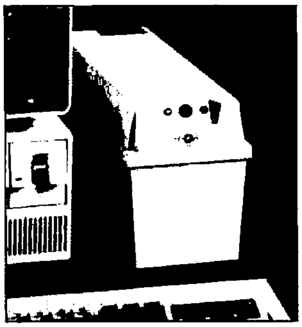
Delta Research has introduced DELTATONE 2.0™, the perfect complement to your repeater controller. The DELTATONE interface (hooks up to your computer's printer port) and your MS-DOS computer offer unlimited 16-digit DTMF tone generation for local or remote programming of the repeater controller. DELTATONE has three programmable tone speed settings. It accepts programming information from a control file created on your favorite PC word processor. Commands and comments can be freely mixed within the file. Its command language allows complete flexibility of tone selection, three sending speeds, selectable one-second delay between digits, a pause (tone off) until a key is pressed and, for level calibration, it will hold the last digit on until a key is pressed. It also has Morse code identification capability.

DELTATONE 2.0 is priced at $149, plus shipping and handling. Contact *Delta Research, P.O. Box 13677, Wauwatosa WI 53213; (414) 353-4567.* Or circle Reader Service No. 205.

TRIPP LITE

A new, compact UL-listed battery backup system from Tripp Lite, featuring 450 VA of power and LAN compatibility, offers superior performance for PC work stations. The BC-450 LAN Battery Backup System is UL-listed under UL-1778 (UPS systems) and supplies 450 VA of continuous power while providing complete spike, line noise and RFI/EMI filtering.

The BC-450 LAN, priced at $449, is part of Tripp Lite's new family of small UL-listed battery backup systems, also available in 275 VA and 375 VA sizes. Contact *Tripp Lite, 500 N. Orleans, Chicago IL 60610-4188; (312) 329-1777, FAX (312) 644-6505.* Or circle Reader Service No. 206.



CHIPSWITCH

The CHIPSWITCH is designed to expand the existing features of the Uniden HR2510/HR2600/LINCOLN 10m radios. It features 30 memory channels with temporary channel lockout and repeater offsets, programmable SCAN/SEEK function, programmable channel UP/DN buttons, programmable microphone UP/DN buttons, programmable transmitter timeout, split frequency operation, programmable transmit frequency range, and priority channel operation (requires additional hardware).

CHIPSWITCH retails for $59.95, plus postage, including the Operator's Manual and Installation Guide. An optional chip socket ($7.50) and priority channel board ($29.75) are also available. Contact *CHIPSWITCH, 4773 Sonoma Hwy., Suite 132, Santa Rosa CA 95409-4269; (801) 224-4130.* Or circle Reader Service No. 204.

THE GRAPEVINE GROUP

The Grapevine Group's new catalog of computer parts and accessories includes the hard-to-find spare parts and upgrades that Commodore C-64 owners need. This 34-page catalog comes in two editions: one for end users, and one for dealers.

Contact *The Grapevine Group Inc., 3 Chestnut Street, Suffern NY 10901; (914) 357-2424, (800) 292-7445, FAX (914) 357-6243* Or circle Reader Service No. 208.

UPDATES

International Radio and Computer, Inc.

Robert A. Pohorence, President of the above company, writes: "We have closed our operation at the Port St. Lucie location and consolidated our business and personnel at our new headquarters in Fort Pierce. The new address is 3804 South U.S. 1, Fort Pierce FL 34982. The telephone numbers are (407) 489-5609 and 879-6868; the FAX number is (407) 464-6386. Also, as of January 1, 1991, International Radio and Computer, Inc., bought the Fox Tango trade name and assets."

C-64 & 1541 Drive 12V Conversion

John Neeley K6YDW writes: "Following is an update on my article, "C-64 & 1541 Drive 12V Conversion," that appeared in the July 1990 issue of *73*, pages 26–30.

"1. Ramsey Electronics no longer carries the TB-6 60 Hz Time Base kit. If you need it for the project, you can build the home-brew version in Figure 3.

"2. In some instances, depending on the terminal program or TNC you use, this 60 Hz clock is not required. Do the power wiring conversion first, then try it out to see whether this is the case. The clock is probably not required if you don't use the disk drive, such as when you use the AEA PK-88 and Digi-Cart programs. This was brought to my attention by readers who did the conversion."

More on the Frequency Standard

Refer to the article, "High Precision Frequency Standard," by Johnson in the January 1991 issue, and the March "Updates" on same. Edward E. Burkhardt of WRTV: "Paul: Typical expected Doppler shifts of domestic geostationary satellites cause frequency shifts in the order of 1 x 10^{-8} which result in color burst changes of 0.03579 Hz from the origin point—not 'about 1 Hz.'

"Even in Los Angeles or New York, color burst can be used only if the station's frame synchronizer is also tied to the atomic standard.

"You [Paul] mentioned your station is locked to WWV 60 Hz as a condition of license. The 60 kHz calls are WWVB. Phase-locking to WWVB results in frequency errors on the order of 1 x 10^{-8} during daytime propagation changes. Please tell me more about your 'condition of license' to be locked to WWVB—this is a new one to me.

"Brad: You should not have used the word 'percent' in '2.79 x 10 to the minus 6th percent'. Rather, it should read, '2.79 x 10^{-6}.'"

Dual Voltage Bench Supply

Angus E. Smiley: "In your October 1990 issue, page 10, 'Dual Voltage Bench Supply,' you never give a part number for Q1, the NPN transistor. I'd like to know what it is."

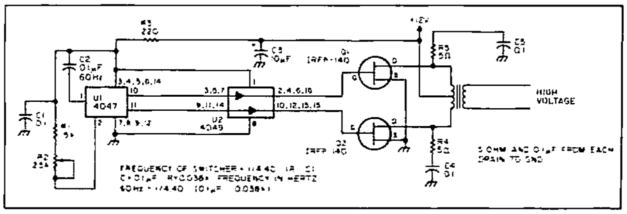
Hugh Wells W6WTU, the author, says you may use a common 2N2222 or 2N3904. Either will work fine.—Eds.

The Switcher-Driver

As promised in WB6IGP's "Above and Beyond" column in this issue: The schematic for his home-brew power supply switcher-driver. The foil pattern and parts placement diagrams are in the August 1990 issue.

Switcher-Driver Parts List

R1	15k	1/4W
R2	25k	pot
R3	220 ohm	1/4W
R4,5,6	5 ohm	1/4W
C1,4,5	0.1 µF	
C2	select 0.1 µF for 60 Hz capacitor; can vary from 0.1–0.12 µF with a resistor value of 38k (25k pot + 15k) pot; allows frequency adjustment.	
Q1	IRFP140 FET100V @32 amps max	
Q2	IRFP140 approx. 200W max	
U1	CMOS 4047 multivibrator	
U2	CMOS 4049 Hex inverter	



Schematic for the power supply switcher-driver in the August 1990 "Above and Beyond."

That familiar adage, time is money, means just that at CIE. CIE makes it possible for students who can study at an accelerated pace to realize significant savings off the cost of an Associate Degree in Electronics. CIE places a restriction only on the maximum time you are allowed to successfully complete your studies in our A.A.S. program (8 six-month terms). If you complete the entire program in two terms, three terms...or seven terms you'll only be charged for those terms... no additional charges for books, lab equipment, or lesson programs.

At CIE, the world leader in electronics home-study, you'll learn from the best and you'll learn at your own pace in your own home at a very affordable price (even more affordable at an accelerated pace). No income interruptions, no conflicting class schedules, no traffic, no hassles, just the academic curriculum to prepare you for a richly rewarding career in electronics.

☐ Yes! Send me CIE's Free School Catalog. AAR03

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

Amateur Radio Software

With construction and gadgets the major topic of this month's *73*, we'll concentrate on a type of gadget here in "RTTY Loop." To wit, I'd like to present some of the most requested "gadgets": RTTY software.

The following information was obtained mostly from flyers supplied by software vendors or, in some cases, from reviews in *QST*. Please check with the vendors for the latest product details and pricing.

Apple II Amateur Radio Software

List compiled by N6BIS, last updated 1/7/91. (These products are not endorsed by Apple Computer, Inc.)

Packet Radio *APR (Apple Packet Radio)*. For use with TNC-2s. Requires a Super Serial card in the computer. Larry East W1HUE, P.O. Box 51445, Idaho Falls ID 83405-1445. Send a blank 3.5-inch or 5.25-inch Apple II disk and a stamped, self-addressed disk mailer.

PACHAM. Uses a two-microchip interface instead of a TNC. DaJu Development Company, 39 Long Ridge Road, Carlisle MA 01741. Price, $49.95.

Morse Code Practice *Morse+Plus Morse Code Tutor*. EPO Software, 7805 NE 147th Avenue, Vancouver WA 98682. Price, $15.95.

Note: The Sept. 7, 1990, *ARRL Letter* mentioned that the Computer Foundation for Handicapped Children has some Morse code programs for the disabled. Contact them at 2645 East Southern, Tempe AZ 85282 for details.

Morse Code & RTTY Operation *HAM*. Sends and receives both Morse code and RTTY. DaJu Development Company, 39 Long Ridge Road, Carlisle MA 01741. Price, $49.95.

Code Machine. COTEC, 13462 Hammons Ave., Saratoga CA 95070. Price, $29.95 (discount if bought with another COTEC program).

RTTY Machine. COTEC, as above. Price, $29.95 (discount if bought in conjunction with another COTEC program).

Satellite Tracking *Apple QuikTrak*. AMSAT, P.O. Box 27, Washington, DC 20044. Price, $25 for AMSAT members; $35 for non-members.

Antenna Design *Antenna Design & Dimensions*. EPO Software, 7805 NE 147th Avenue, Vancouver WA 98682. Price, $9.95.

Antenna Trap Designing. Larry East W1HUE, 119-7 Buckland St., Plantsville, CT 06479. Send blank formatted disk with stamped, self-addressed return disk mailer.

Logging *Electrolog II*. EPO Software, 7805 NE 147th Avenue, Vancouver WA 98682. Price, $18.95.

Contest Log & Dupe Sheet. EPO Software, as above. Price, $13.95.

Macintosh Amateur Radio Software

List compiled by N6BIS; last updated 11/24/90.

Packet Radio *NET/Mac (KA9Q TCP/IP)*. Supports AX.25 and NET/ROM as well as TCP/IP functions. Requires a TNC with KISS mode. Doug Thom N6OYU, 1405 Graywood Drive, San Jose CA 95129. Send formatted 800K Macintosh disk with stamped, self-addressed return disk mailer. Also available via anonymous FTP from apple.com (/pub/ham-radio) and platypus.uofs.edu (/pub/HAM-RADIO); on the Digikron Systems BBS at (408) 253-1309; the WB3FFV BBS at (301) 625-0817, 625-9482, and 625-9663; and the N8EMR BBS at (614) 895-2553 (or via AMPR.NET FTP at 44.70.0.1). The KA9Q package is copyrighted, but free for noncommercial use.

MacRatt with FAX. Terminal program for use with AEA's PK-232 multimode controller. Supports packet, CW, RTTY, AMTOR, and facsimile. Includes computer-to-TNC cable. Advanced Electronic Applications (AEA), P.O. Box C-2160, Lynnwood WA 98036. Price, $59.95.

Morse Code Practice *N6MZV Morse Trainer*. RT Martin, N6MZV, 10382 Orange Avenue, Cupertino CA 95014. Also available via anonymous FTP from apple.com (/pub/ham-radio). Price, $25.00.

Morse Tutor. Jack Brindle WA4FIB, Brincomm Technology, 3155 Resin Street, Marietta GA 30066. Send formatted 800K Macintosh disk with stamped, self-addressed return disk mailer. The program is copyrighted, but free for noncommercial use.

MacMorse. David A. Kail, 700 Marine Parkway #314, New Port Richey FL 34652. Price, $29.95.

Zihua Morse. Zihua, P.O. Box 51601, Pacific Grove CA 93950. Price $39.95 without speech synthesis; $65 with speech synthesis.

RTTY *MacTTY*. Summit Concepts, Suite 102-190, 1840 41st Ave., Capitola CA 95010. Price, $39.95.

Logging *LOGic*. Personal Database Applications, 2634 Meadow Bend Court, Duluth GA 30136. Price, $75.00.

FDLog! System One Control, 3900 85th Ave N, Suite 200, Brooklyn Park MN 55443. Price, $29.95.

Satellite Tracking *QuikMac*. AMSAT, P.O. Box 27, Washington, DC 20044. Price, $40 for AMSAT members; $50 for non-members. Requires Microsoft BASIC.

Satellite Orbit Prediction Program. Macintosh conversion of W3IWI program. Earl Skelton, N3ES, 6311 29th Place NW, Washington DC 20015. Send formatted 800K Macintosh disk with stamped, self-addressed return disk mailer; or send SASE for source listing. Requires Microsoft BASIC.

MacSat. BEK Developers, 1732 74th Circle NE, St. Petersburg FL 33702. Price, $10.00.

MacSat 3.0. Geodetic Research Services Ltd., P.O. Box 3643, Station B, Fredericton, N.B. E3A 5L7, Canada. Price, $50.00 (add $10.00 for airmail postage and handling).

Satellite Helper. MacTrak Software, P.O. Box 1590, Port Orchard WA 98366. Price, $59.95.

Satellite Pro. MacTrak Software, as above. Price, $99.95.

Propagation, Gray Line, DX Headings *DX Window*. Creates on-screen an azimulhal equidistant projection (great circle) world map centered on your QTH, with day/night terminator. Engineering Systems, Inc., P.O. Box 939, Vienna VA 22183. Price, $39.95.

Skycom 1.1. Enter solar flux and get propagation predictions to desired areas of the world. Engineering Systems, Inc., as above. Price, $39.95 ($59.95 with Skycom 1.5).

Skycom 1.5. Provides sunlight status at both ends of the path; MUF, F0F2, and FOT frequencies; S/N ratio of the link, and other information. Engineering Systems, Inc., as above. Price, $39.95 ($59.95 with Skycom 1.1).

DX Helper. MacTrak Software, P.O. Box 1590, Port Orchard WA 98336. Price, $34.95.

Sun Clock. Desk accessory. Displays a map of the world with day and night areas. MLT Software, P.O. Box 98041, 6325 SW Capitol Highway, Portland OR 97201. Price, $17.00.

Radio Control *ICOM IC-735 Control*. KE6FG Software, 9763 Pali Ave., Tujunga CA 91042. Price, $49.95.

Test Preparation *Ham Stacks*. HyperCard stacks containing all of the questions in the current question pool for each license class. Diana Syriac N1GZS, 49A Meadow Pond Drive, Leominster MA 01453. Send two formatted 800K Macintosh disks with stamped, self-addressed return disk mailer. Also available via anonymous FTP from the pub/ham-radio directories on apple.com and platypus.uofs.edu.

Collections and Miscellany *MacNet*. Public-domain programs (currently on nine disks) contributed by Macintosh packet users. Includes test preparation, contest logging, propagation prediction, satellite tracking, and amateur television. John D. Seney KB1HE, 144 Pepperidge Dr., Manchester NH 03103. Send formatted 800K Macintosh disks with stamped, self-addressed return disk mailer. Contributions of public-domain programs encouraged.

"Project Mac." Contest logging, antenna design, satellite tracking, clip art, etc. Microsoft BASIC required for many (but not all) of the programs.

Stan Horzepa WA1LOU, 75 Kreger Drive, Wolcott CT 06716. Send three formatted 800K Macintosh disks with stamped, self-addressed return disk mailer.

Amateur Radio Software for Macintosh. Extensive catalog including logging, Morse code, Novice, gray-line, satellite tracking, contesting, packet, and CW programs. ZCo Corporation, P.O. Box 3720, Nashua NH 03061.

Amateur Radio #1. Contains satellite tracking, Morse code practice, Ohm's law calculator, and pad design programs. Kinetic Designs, P.O. Box 1646, Orange Park FL 32067. Price, $4.00.

Red Ryder 9.4. Terminal emulation program, suitable for packet radio. Kinetic Designs, P.O. Box 1646, Orange Park FL 32067. Price, $4.00.

MacScience BBS. Various ham-related applications, including antenna design, propagation, WEFAX, packet, and Morse code. Tel. (408) 866-4933.

Digikron Systems BBS. Various ham-related applications, including logging, propagation, Morse code, and packet. Tel. (408) 253-1309.

WB3FFV BBS. Various ham-related software, including packet, contesting, and Morse code applications. Tel. (301) 625-0817, 625-9482, and 625-9663.

N8EMR BBS. Various ham-related files, including packet, Morse code, DXing, and contesting software; AMSAT bulletins; and several ham newsletters. Tel. (614) 895-2553. Also available on AMPR.NET at 44.70.0.1.

Tandy Color Computer Software

List compiled by N1ENA, last updated 1/15/91.

CoCoPACT (for 64K CoCo1 or CoCo2) and CoPACT3 (for CoCo3). Monty W. Haley WJ5W, Rte. 1, Box 210-B, Evening Shade AR 72532-9735. Mike purchased this package about a year ago and it came with free PBBS software. Both programs have split screen operation, 40k QSO buffer, 10 macros, and an editor for off-line use. CoPACT3 (for CoCo3 only) uses 80-column display, additional 24K buffer, and optional 2400 baud serial port data rate. Price, $21.95 postpaid for both programs.

CoCoPacket. Brian Carling, 5131 Raywood Lane, Nashville TN 37211. Mike never tried this program. It's mentioned in the packet software list on page 5-5 of the ARRL's *Your Gateway To Packet Radio* book. Price unknown.

SMARTY2 (for CoCo3). James A. Sanford WB4GCS/NNN0HDF, 20 Glen Forest Drive, Hampton VA 23669. This is a RTTY program for the CoCo3 with an external terminal unit. It has split screen, SELCAL, several Baudot speeds and 300 baud ASCII. Mike bought this one about two years ago. Price, $15.00.

BBS: Thermal Fusion BBS. Greenville SC. (803) 862-7544, 300-9600 baud, 8N1. This is a free Ham/OS9 BBS with CoCo ham radio programs posted on it.

My sincere thanks to Patty Winter N6BIS and Mike Nadeau N1ENA for the information presented this month. No doubt there are more such programs "somewhere out there." And as you, the loyal readership, let me know about them, I'll be sure to share the information with the rest of you! Meanwhile, I've got more goodies on tap for next month, so don't miss that edition of "RTTY Loop"!

HOMING IN

Radio Direction Finding

Joe Moell PE KØOV
PO Box 2508
Fullerton CA 92633

T-Hunting Stolen Cars

Radio direction finding (RDF) began as a way of finding the position of ships during World War I. The first transmitter hunters were sailors. Then the military put it to work locating aircraft and, as a result, RDF played a vital role in World War II. Later, search-and-rescue crews, the FCC, and ham radio operators discovered its usefulness.

Now, RDF has become the latest tool of local law enforcement. Peace officers across the country are learning to T-hunt, and they're excited about it.

In 1978, an entrepreneur named Bill Reagan wondered if RDF technology could reliably locate stolen cars and hijacked eighteen-wheelers. He and Sheldon Apsell, an engineer and radio ham, developed the concept and called it "LoJack ™," to contrast with "hijack."

It took five years to design the equipment, and another two years to prove the feasibility of a wide-area RDF dragnet to authorities in their home state, Massachusetts. Test hunts of 800 simulated stolen vehicles had a 100 percent success rate, averaging 11 minutes homing time. In July 1986, the system became available to the public. Today there are 300 police cars with DF units, and 70,000 vehicle transmitters, in Massachusetts.

LoJack expanded into southeast Florida in 1988, then into New Jersey and southern Michigan. Southern California went on line last summer, and Chicago four months later.

The new Southern California Stolen Vehicle Recovery Network (SVRN) represents a $1.7 million investment for LoJack. The company donated the SVRN computer software and police RDF units. But the investment should pay off well, because the SVRN could take a big bite out of the auto theft industry here.

Over 129,000 vehicles are stolen in Los Angeles County every year, which works out to one every four minutes. Average loss per theft is $6,000. With an extensive ad campaign on television and in new car dealer showrooms, LoJack hopes to install 20,000 transmitters in the first year of business here, and expand the SVRN to other Southern California counties.

Cops Turn On the T

To prevent false alarms, the LoJack unit (LJU) is independent of any other alarms in the car. The transmitter is turned on only by police, and only after the owner reports that the vehicle has been stolen. The whole process is automatic.

When police routinely enter a vehicle into the CLETS state-wide stolen vehicle computer system, the information is transmitted to the special SVRN computer at police headquarters via a 9,600 baud landline link. The SVRN computer checks its data base to see if there is a LoJack match to the stolen vehicle's ID number. If so, Sector Activation Transmitters (SATs) broadcast a coded message to the LJU, causing it to start transmitting once every 15 seconds. The entire activation process takes about a minute.

Seven SAT sites ringing Los Angeles County, with 300 watts ERP at each site, insure that the LJU will be activated, unless the thieves have driven it into an RF screen room. The activation code is sent twice, five minutes apart, then repeated every half hour for good measure.

To save power and to prevent interfering with any DFing in progress, the LJU goes into a low duty transmit mode when the vehicle is first reported stolen. When the car's transmitter is first heard by a police cruiser, the officer radios headquarters, giving the five-character code from the RDF display. The linked computers respond with the vehicle ID and description, so the officer knows what he's DFing.

This inquiry also causes the SATs to broadcast a "query mode" message to the LJU. That increases the transmit rate to once per second, to speed up the homing process. After the vehicle is recovered, the computer tells the SATs to deactivate the LJU, and reset it to be ready for use again if needed.

The police need not know if a stolen car has LoJack when they enter it into the CLETS computer. The SVRN computer does not alert police when it sends out an activation. A LoJack T-hunt doesn't start until the signal shows up on the RDF set (called a PTC) in an officer's vehicle. At that time, the officer knows he is only a few miles away from the hot car.

Hundreds of Hunters

It's hard for a thief to elude the system: 465 police and sheriff cruisers in Los Angeles County have PTCs. That's over 50 percent more than in Massachusetts, even though Los Angeles County is one-third the size of the Bay State. Installations are being planned for police helicopters and boats, too. All but one of the law enforcement agencies in Los Angeles County are participating in the program.

Micrologic Corporation makes the PTCs, which use "pseudo-doppler" technology in the VHF "high band," between 150 and 174 MHz. The electronically-rotating antenna array has four whips, in a square pattern, on the squad car's roof. The display unit (see the photo) resembles the commercial VHF Doppler RDF sets for sale to hams and mariners. It has a 16-LED direction indicator, S-meter, and five-character readout.

The PTC is more sophisticated than a typical Doppler RDF set. It gets a bearing on each transmission burst, holds it, and displays the code of the vehicle on the five-character readout. All activated LJUs transmit on the same frequency. Officers can get bearings on more than one car at a time, distinguishing them by their unique codes on the display. To prevent confusion when closing in, the PTC can be locked to display bearings from only one selected LJU.

The LJU, built by Motorola, is the size of a chalkboard eraser. It is mounted in the vehicle in one of 35 inconspicuous places, randomly selected. Usually the owner has no idea where his LJU is. No warning stickers are put on the vehicle. That's good, because a significant number of vehicles are taken at gunpoint. It would not be good if thieves could force owners to reveal the LJU's location so they could destroy it.

Transmitters put out two watts, and draw only 400 mA when transmitting. If the thief tries to disable the LJU by disconnecting the vehicle battery, an internal sealed lead-acid battery will keep it on the air. Even if that battery runs down, the LJU will remember its mode (activated or not), and come up in that mode when the battery is reconnected.

Results Guaranteed

So, how are Southern California peace officers doing at T-hunting? Very well, thank you. Since the system came up on July 20, 1990, there have been 22 stolen vehicle activations. All cars were recovered within 24 hours. Average time was three-and-a-half hours. The fastest took only 14 minutes from the time the report was filed.

Two recoveries here resulted in busting large theft rings. Arrests were made in a quarter of the Los Angeles cases, which is typical for LoJack pursuits. The national average for non-LoJack car thefts is arrests in only 5 percent of the cases.

Auto theft has gone down 9 percent in Massachusetts, and some insurers there offer lower rates to LoJack-equipped vehicles. About 4.5 percent of all new cars sold in that state get equipped with LJUs.

LoJack was careful to design a system that is as reliable as possible, and stands by it with a two-year warranty. The company will refund the LJU's purchase price if the vehicle is not recovered within 24 hours of being reported stolen.

Police like the system because it enhances their safety. All too often, police officers have been killed or injured in the line of duty when they unwittingly pulled over a stolen car. Officers know that a vehicle with a squawking LoJack unit has been reported stolen, and can take appropriate precautions when approaching it.

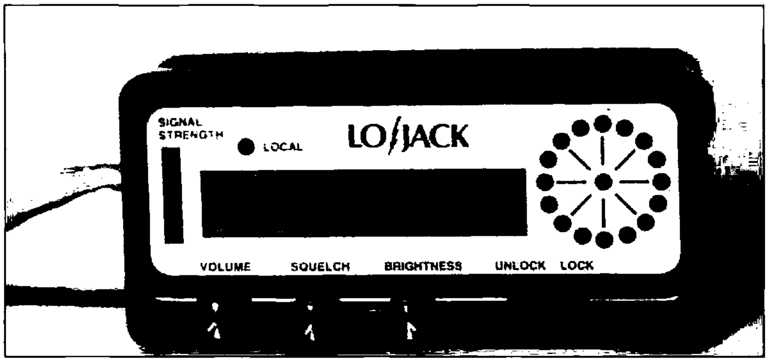
Of course, the LoJack system is not perfect. For one thing, the vehicle must be reported stolen before DFing begins. That's good because it prevents false alarms. But, if the owner doesn't discover the theft promptly and report it, the vehicle could be long gone. That's another disadvantage—the limited range of the dragnet. Doppler technology limits each squad car's tracking range to about five miles. The helicopters will do better, of course.

The company claims that short range isn't a problem, because of the large number of PTC-equipped police cruisers. Furthermore, thieves usually let stolen cars sit in a nearby safe place to "cool off" before driving them out of the state, or out of the country.

Perhaps, but one stolen Jeep in Los Angeles was recovered just two minutes before the 24-hour guarantee ran out. Apparently it had been driven 200 miles out of the area and back again.

Add to this the possibility of a slow-up due to down time at the CLETS statewide computer, and you have a system that is not foolproof. In Massachusetts, the recovery rate has dropped slightly every year, from 97.9 percent in 1987 to 94.4 percent in 1990. Still, that's an impressive record. It speaks well for the robustness of the LoJack system design and the DFing abilities of law enforcement officers.

Too bad the PTCs don't tune to two meters. I could use the help of 465 police cars on some super-tough competitive hunts.



The LoJack dashboard unit includes a 16-LED RDF display, S-meter, and 5-character readout showing the ID code of the vehicle being tracked.

T/R Controller Relays

The last few months we've done a lot of building in this column! This month we'll tie up several loose ends. The two projects, the T/R controller and the universal transmitter, are both easy to build and get running. Very few components are critical. Your local Radio Shack store can provide most of the parts needed. However, herein lies the first problem.

The onboard relays used by the T/R controller have been discontinued from Radio Shack. However, some stores still have them until the stock runs out. Because the PC board pattern is designed to use this particular relay, nothing else will fit the board. Unless you happen to come across the same relay surplus! Of course, you could use a junk box relay mounted off the board as I have done. Just be sure the coil current is not more than the switching transistor can carry. Down the line, if there is enough interest and a suitable relay is found, the PC board may be re-designed.

Some readers complained that the sidetone will not operate. There is a simple fix for this problem. Be sure the sidetone-in and sidetone-out pins are connected together! If they aren't, the tone oscillator won't work. Speaking of the sidetone, you don't have to build both the sidetone and the relay switching if you don't need one or the other. If you need a sidetone generator and amplifier, just build that part of the circuit. To turn on the sidetone, just apply +12 volts to the sidetone-in pin.

If you plan to operate the complete T/R controller with a transmitter, such as the universal transmitter, make sure you operate both the T/R controller and the transmitter from the same power supply.

As I noted earlier, a large battery bank supplies all my power. All my equipment is operating from this source. There is no problem using the controller this way. However, if you operate the T/R controller from a +12 volt supply, AND the transmitter from a DIFFERENT +12 volt supply, things may not work correctly, or work at all. The fix is simple. Just be sure that all devices are operating from the same +12 volt source.

That should reduce any mistakes and provide you with a working T/R controller in no time. Remember, FAR Circuits (18N640 Field Court, Dundee IL 60118) can provide PC boards for both the T/R controller and the transmitter.

The Universal Transmitter

The universal transmitter contains some gray areas, also. The following hints should help clear things up.

The oscillator will work with just about any crystal. There are no tuned circuits in the oscillator. VXO operation is possible, but I've had some really strange results with the crystals I've been using. On 30 meters, I've gotten about 5 kHz worth of swing. As I discussed in an earlier column, almost all of the frequency shift is bunched up on one end of the VXO capacitor.

> ***"Signal reports ranged from 529 to 599; you CAN'T be QRP!"***

My crystals came from Jan Crystals. They are in the HC-25/U holder and have a 20 pF load capacitance. I ordered a new set of crystals from International Crystal, hoping to get a different VXO swing. I ordered AT cut, fundamental crystal in the HC-6/U holder with a load capacitance of 30 pF. The crystal's frequency is 10.106 MHz. In the VXO, I used a 365 pF variable capacitor. I'm not really sure of the exact value of the capacitor, since it came from the junk box.

With the new crystal in the circuit, VXO swing was still only 6 kHz. I tried to add some inductance, but did not see much improvement. I took the same crystal and installed it in a different home-brew transmitter, using a different oscillator scheme. OHMYGOSH! Did I ever get a surprise. With the crystal in the second VXO, I had a frequency swing of 10 kHz, from 10.102 to 10.112.5 MHz. The VXO should not have moved the crystal's frequency down, but it sure did. In the universal transmitter, the VXO swing is upward in frequency from 10.106 to 10.110 MHz. Leave the 0.01 feedback capacitor in the circuit even if you plan to add a variable capacitor to warp the crystal's frequency. You might want to experiment with different values of feedback capacitors. Then let me know the results of your tests, and I'll put them here in this column.

Construction of inductors L4 and L5 need some clarification. Make the wire leads coming from L4 and L5 a different length so that it will be easier to tell which is which. Coil L4 is in series between the collector of Q3 and the 22 ohm resistor. You can check this out quite easily by making sure the collector of Q3 has +12 volts applied to it when the key line is grounded. If you have no voltage on Q3's collector, you've gotten your wires crossed.

Coil L5 is a bit easier to check. One end of L5 goes to the junction of Q4 and the 47 ohm resistor. The other end of L5 goes to ground. With an ohmmeter you should see zero ohms from this point to ground. If you see 47 ohms, you're reading the 47 ohms from the resistor to ground, and coil L5 is then incorrectly wired.

30 and 40 Meters

I was working on a version of the transmitter one night for 30 meters. I didn't have all the correct capacitors, though, so I changed the output filter to suit what I did have.

Use these values for 30 meters. L1 and L2: 12 turns #22 on a T-50-2 core. Jumper the pads used by L3. Instead of the 330 pF cap, use 270 pF. Instead of the 680 pF, use a 560 pF capacitor. Omit the second 680 pF capacitor. Install the second 270 pF capacitor on the antenna side of the filter. You end up with two cores and three capacitors.

For 40 meters you can use the following: L1 and L2; 14 turns #22 on T-50-2 core. Replace the first 300 pF with 470 pF. Jumper the pads used by L3. Delete the second 680 pF capacitor. Replace the first 680 pF with 1000 pF (0.001) and the last 300 pF capacitor with 470 pF. Use silver-mica capacitors in both filters for best results.

Since I don't have crystals for 14 MHz, I did not work out the filter values needed for that band.

If Radio Shack is out of stock of the 100 μH RF chokes, wind your own. Use ten 10 turns of #28 on FT-50-43 core.

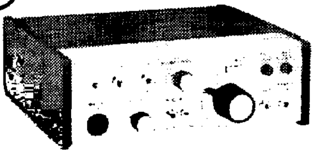
The final might be hard to locate. I still have a good supply of hamfest PAs lying about, and that is what I used. If you can't find the part listed, try one of these: RCA 4013, 2N3553, and 2SC2075. Also try the more readily available 2N3053 and 2N3866. Just be careful, as the 2N3866 might become unstable if the leads are too long. Keep the leads short, ⅛ inch from the board, and you should have no trouble.

That should clear up any loose ends on the transmitter. I've worked all up and down the East Coast on 30 meters using this little rig. The West Coast and DX are easy prey late into the night on 30 meters. Signal reports ranged from 529 to 599; you CAN'T be QRP! I know you'll find a spot for this project in your shack.

Since the U.S. postal rates have just gone up, letters without an SASE will go unanswered. Sorry about that, but the postage really cuts into my Diet Coke fund. If you don't want to communicate via the mail, try one of these. Via Compuserve, ID# 73357,222. America OnLine, Michael1087. Delphi, QRPER. I forget what my ID number of Prodigy is, but I'm on that service also. You can also reach me via packet: WB8VGE @ KA8Z BBS. Whoa! It's 1991. One can't live by CW alone! 73

AMATEUR TELEVISION

SMILE! YOU'RE ON TV



Only $329

Designed and built in the USA
Value + Quality from over 25years in ATV...W6ORG

With our all in one box TC70-1 70cm ATV Transceiver you can easily transmit and receive live action color and sound video just like broadcast TV. Use any home TV camera or VCR by plugging the composite video and audio into the front VHS 10 pin or rear phono jacks. Add 70cm antenna, coax, 13.8 Vdc and TV set and you are on the air...it's that easy!

TC70-1 has >1 watt p.e.p. with one xtal on 439.25, 434.0 or 426.25 MHz, runs on 12-14 Vdc @ .5A, and hot GaAsfet downconverter tunes whole 420-450 MHz band down to ch3. Shielded cabinet only 7x7x2.5". Transmitters sold only to licensed amateurs, for legal purposes, verified in the latest Callbook or with copy of license sent with order.

Call or write now for our complete ATV catalog including downconverters, transceivers, linear amps, and antennas for the 70, 33, & 23cm bands.

The Tech Answer Man

Michael J. Geier KB1UM
℅ 73 Amateur Radio Today
Forest Road
Hancock NH 03449

Letters, Letters . . .

Lots of letters have been coming in, so perhaps now is the time to respond to some of them, and to cover a few interesting topics along the way.

Mick W6FGE asks whether there's any point to expensive, wide-audio bandwidth mikes since the radio cuts everything above about 2.4 kHz off anyway. Well, Mick, it's a good point. A mike with response out to 20 kHz is certainly wasted in amateur communications work. What makes some of the more costly mikes worth their prices is their response *within* the transmitted bandwidth. You'd be surprised how much variation there is between different mikes. The best ones for SSB are dynamics or ceramics, which have a rising frequency curve that adds "punch" to the voice, and helps you to get heard through the inevitable QRM. But the shape of that curve, and the frequency at which it peaks, can really affect the sound. Conversely, the best mikes for FM tend to be condenser mikes, which have a fairly flat response. The cost of a mike is not directly related to its sound. In fact, I've heard some really cheap mikes which sounded great, and some expensive ones which were only so-so. But, some higher-priced units are distinctly crisp and great on the air. The obvious way to find out is to try them. A cheaper alternative is to ask stations you QSO with what kind of mikes they are using. Don't just ask the good-sounding ones—find out which bad ones are out there, too. As for headsets, I have found that common "walkperson" units have far better fidelity than is necessary. They do fine for radio work, unless you need to shut external noise out, in which case you need the around-the-ear kind. As you point out, expensive hi-fi headsets are a waste.

On the subject of audio fidelity, Peter W1UO responds to my "Why Rigs Sound The Way They Do" column and relates his experiences with "hi-fi" SSB. He says that he once worked for the Voice of America, and they used HF SSB for their overseas feeds. Several fidelity-enhancing techniques were used, including diversity reception, phase-locked exalted carrier detection and wideband (6 kHz) SSB filters, each about the size of a loaf of bread! (Wow—imagine the size of a '940 with filters like that!) He says that overseas signals sounded like local FM broadcasts! See, folks, I told you so!

Guillaume K0OKP asks whether AM is permitted on the 220 MHz band. Let me check my ARRL handbook . . . Yup, it sure is. Unless they've changed that since 1985 (OK, OK, I need a new handbook), and I haven't heard of any such change. I doubt, though, that you'll find too many people to talk to up there on that mode. FM is the popular mode these days, with SSB and CW used for weak-signal work. But hey, give it a try, you never know.

A 17-year-old ham named Sean (no call on the letter) says that someone stole his TS-430S (*shame* on them!) and he can't afford another one. He has a digital shortwave receiver and wants to know if he can use its local oscillator to drive a preamp and power amp to make a simple transmitter. Sean, I'm afraid it just isn't that simple. In a superheterodyne receiver, which virtually all modern sets have, the local oscillator does not run at the frequency you are receiving! There is a rather large frequency offset, and that offset depends upon the first IF frequency. For instance, if the first IF is at 10.7 MHz, the local oscillator will be either 10.7 MHz higher or lower (depending upon the receiver design) than the frequency to which you are tuned. The only ways I can think of to get the frequency you want would be to design a mixer and inject another local signal to shift the frequency, or to reprogram the frequency on transmit so that it is in the right place. Either would be a great deal more trouble than it is worth. And there are other problems, such as stability, purity and signal level. All in all, consumer shortwaves just don't have what it takes to make decent ham rigs. A far better alternative would be to buy a cheap older transceiver at a hamfest and use your time and ingenuity to fix it up. In the end, you will be much happier with the results. And, you won't risk ruining your shortwave in the process.

Kenneth KA8RUA describes his frustration at trying to get schematics and service data for telephone gear such as cordless phones and answering machines. He asks whether it is legal for the manufacturers to withhold such information. Well, as far as I know, there is no law requiring them to give their data out. And I, too, have run into this brick wall regarding a broken answering machine. I suppose there could be some law prohibiting the general public from tampering with equipment connected to the phone lines, but I don't think so. I know of at least one major manufacturer that sells service manuals for their telephone gear. So perhaps the others are just being pigheaded and greedy, hoping you'll buy another unit or send yours in for an expensive repair job. I agree, it stinks. Let's be glad the ham manufacturers have more sense than that!

Dean KF7CR asks several questions, including some already covered in previous columns. But let me give them a whirl. Dean, PLL works by generating a stable digital pulse at a required frequency and then voltage-controlling an analog sine-wave oscillator until it matches the digital reference. The result is a programmable, crystal-accurate local oscillator. Because it's a two-way process (controlling the oscillator and then comparing its output frequency), it is by definition a loop. Hence the name, "phase-locked loop." And yes, your pocket digital shortwave works that way. For a more detailed explanation, please see my column in the March 1990 issue of *73*.

Packet radio is, as you guessed, a form of BBS over the air. It is also many other things, including a nifty auto-forwarding system which lets you place a message on your local BBS and have it delivered in a day or two at a very distant BBS, with no transmission errors. It is called "packet" because the data is transmitted in groups of characters, or packets, with each packet automatically including the originating callsign (yours), the destination BBS and callsign, and error-detecting codes. During packet reception, any detected errors cause the packet to be resent until it is received intact. There's lots more to it, but that's the basic idea. Packet is very useful and fun, especially if you have ham friends in other states or countries, because you can keep in touch without having to be on the air at the same time they are! Get a TNC and try it out! If you already have a 2 meter rig, even a walkie, it is fairly inexpensive and definitely worth it.

As for your noise suppression problems, I think some of them may be very difficult. Dimmers and fluorescent lights generate fast-rising pulses which are just plain stubborn. You are probably best off replacing them with regular switches and incandescent bulbs. As for your VW Rabbit ignition noise, wow—that is the worst I've ever heard of. Since the car eats ignition cables in 5,000 miles, I suspect you have a real problem. Perhaps the ignition resistor relay is stuck. That would allow full starting current to flow even after the engine is running. I had a car with this problem once, and it ate points as fast as yours eats wires. Your high voltage must be *way* too high.

Also on the subject of interference problems, **Winston KB6DHB** asks for help because his rig gets into his TV and stereo speakers, and even a low-pass filter hasn't helped. From what you describe, Winston, it sounds like plain old overload. Too much RF is getting into the TV and stereo. A low-pass filter only helps if the problem is harmonic output from the transmitter, and does no good at all for simple overload. Check to see if the TV gets interference on all channels from 2 to 6. That's a good clue. If it's only channel 2, it could be harmonics. Even with the low-pass filter, some small amount of harmonic energy could be escaping. Also, your G5RV antenna is inherently unbalanced, because one leg is longer than the other. Try a balun at the antenna, or go to a standard dipole. Perhaps that will help keep RF from crawling back up the coax shield. You could also try a line filter, but try disconnecting the TV antenna or cable feed first. If the problem goes away, the interference is getting in from the antenna input, and a line filter will do no good.

Finally, a prospective ham named Robert asks how we get meters from hertz, as in the 20 meter band being on 14 MHz, etc. Well, first let me state that the meter band designations are only approximate, and can never be exact because they are describing more than one specific frequency. But it works like this: For any given frequency, a wave will have traveled a definable distance before its next peak occurs. Thus, the resulting wavelength will get shorter as the frequency goes up, because the wave doesn't have as much time to travel before the next one comes along. The wavelength can be calculated and expressed in meters, feet, or anything you like. A simple conversion from time units (MHz) to distance (meters) will do the trick. The formula is: wavelength in meters = 300/frequency in MHz. The 300 is called a "conversion factor," and is required to relate seconds and meters. As for your other questions regarding the best choice of equipment and proper operating procedure, go visit your local ham club and you will get more advice than you probably want! (We hams *love* to talk about that stuff.) Also, there are some good books available from the ARRL and other organizations. And, of course, don't miss the great product reviews in *73*!

Well, folks, that's about it for this month. Keep them cards and letters coming. But please, save your stamps and return envelopes. It is very rare that I can send individual replies—there's just too much to do. Thanks for your understanding. 73

NEW
From Micro Computer Concepts
RC-1000 REPEATER CONTROLLER
• Autopatch
• User Programmable CW ID, Control & User Codes & Timeouts
• Intelligent CW ID • Auxiliary Outputs • Easy to Interface • Remote Base/Tape • Reverse Patch • Tailbeeps • 12 VDC Operation • DTMF Decoder with Muting • Telemetry • Control RX • Response Tones • Programmable COS Polarities • Detailed Application Manual with schematics • 90-Day Warranty
Wired & Tested w/manual $239.95

Never Say Die

Continued from page 4

palace. I've sat in Geneva representing the U.S. at a world conference. I've addressed the FCC commissioners in hearings. I've helped a youngster in Burma find a wife in Singapore and settle In the U.S. I've visited Father Moran in Nepal. I've helped a ham I met in Yugoslavia move to the U.S. Ditto a French ham. No, I'm not bragging, I'm telling you what *you* can do. I'm telling you what the youngsters you mentor can do.

You're a haml Through amateur radio you can learn about FM, sideband, spread spectrum, computers, digital audio, digital communications, television, slow-scan, RTTY, satellite communications, antennas, feedlines, gates, memory chips, synthesizers, telephone switches, facsimile, radar, LORAN, underwater sound, moonbounce, meteor scatter, aurora communications, and what people are like in around 400 countries.

Whenever I see a picture of the big dish at Arecibo I remember climbing up into it with Sam W1FZJ. And I remember being part of the team that used this 1,000-foot dish to make 1200 MHz ham contacts all over the world.

The real key to what we are going to do when we grow up lies In learning. If we use our time well, we'll be ready for whatever opportunities the world presents. Like Alfie, the world presents opportunities and they are lost due to our blindness to them. I'd already been exposed to technology through my grandfather, who was an inventor, so I was able to confidently tackle learning about radio.

Are you daunted by packet? By satellite communications? Perhaps, no matter your age, it's time to be adventurous and become an expert In a new aspect of the hobby. We need pioneers, even if they need walkers to get around. Even if you're 80, you still have a lot of growing to do. It's not too late to plan what you're going to do when you grow up.

And once you have some perspective on life, maybe you can share what you've learned with some youngsters. Teenagers need mentors. Their parents seldom have enough dispassionate perspective to help. So that leaves you. And if you do mentor some youngsters, are you going to be passing along your beliefs and prejudices, or can you give them some straight dope which will really help them cope with their lives?

You remember what teachers were like, so you know how little help they can be. You may even remember about parents. And you're seeing the values today's television provides. Some guidance! If you believe TV, all techies are nerds and geeks. Great role models.

In addition to giving talks on entrepreneuring at colleges I also enjoy talking with 5th graders and helping them see some hints as to the possibilities they've got. And I'm mentoring some college students, too. I only wish there was a medium where it would be

QSL of the Month To enter your QSL, mail it in an envelope lo *73*, WGE Center, Forest Road, Hancock, NH 03449. Attn: QSL ot the Month. Winners receive a one-year Subscription (or extension) to *73*. Entries not In envelopes cannot be accepted.

possible to reach kids with some unbiased information on how the world works and how they can not just cope with it, but also help improve it during their tenure.

As for me, I've never had any illusions about my growing up. It's never been a goal. Now I find that's par for creative people, so I guess I don't feel as defensive as I did when I was a kid about making the world conform to me instead of my conforming to it. World, shape up, and get a move on, I haven't got all day!

Are you doing your homework? Are you reading magazines and books, talking with people, building things? Where were you in 1975 when microcomputers came along? Where were you when I was preaching computers? I was 53 then. Did I face this whole new technology and give up? No way! Within a year I was giving lectures on computers to computer professionals. Sure, I did a lot of homework. I still meet people who took my advice at the time and got into computers. Some became fabulously rich. Some didn't. But everyone enjoyed what they were doing.

We have similar opportunities today with direct satellite broadcasting, high definition TV, digital audio, digital TV, digital signal processing, personal telephones, data compacting. . . it's an endless and exciting world ahead in technology. And amateur radio is the key to this world for youngsters.

Are you learning and teaching? Are you mentoring? Or are you grousing about no-code, how bad things are on our bands, and being in general a useless negative curmudgeon? Sure, I see the problems, but I love problems because they call for creative solutions. The fact that you are allowing a few idiots to screw up 14.313 every day and do nothing more than wring your hands about it is pathetic.

Sure, it takes confidence to see a need and actually do something about it. That's what got me into publishing in the first place. I didn't know anything about it, but I knew I'd learn. And, as I mentioned recently, I'm still learning. I still go to publishing conferences and attend seminars. Much of the time I should be teaching 'em, but I know I've plenty more to learn.

That's what keeps me reading piles of magazines and a couple books a week, year after year. One whole end of my home is sagging under the weight of my library.

I love to learn about music, loo, so somehow I manage to listen to a half dozen or so CDs a day. The music industry is fascinating and I'm having a ball with it. There are tremendous business opportunities in this field, too. Music and technology have merged, which is great for me.

And if radio and audio don't get you excited, how about becoming an electromagnetic expert and helping find out more about how EM fields affect living cells? You can get a download of references on the *73* BBS and see what I've read so far.

Are you ready to give a talk on the maglev? On NMR? Are you game to help some school classes learn about electronics and communications, if I can get our schools to set up these courses? Or are you spending your declining years pontificating on 75m? Or adding to the pile-ups on 20m?

Ooops, my soapbox is beginning to come apart.

When I Grow Up. . . Part II

Amateur radio may be a great key to learning about technology, but how many of us leave the key in the drawer and don't use it? I'd like not only to get you to take that key out and start opening doors for yourself, but to give copies to youngsters so they can open doors and open up their lives. I know what an impact it's had on my life—how about you? Any chance of your writing to me about it?

The opening doors are entries to learning possibilities. How can we learn? How do we educate ourselves to take advantage of amateur radio's potentials?

In retrospect, I think I learned less during my years in college than I have in almost any year since then. My college wasn't set up to really teach. It was geared to students memorizing data in order to pass tests. I found it profoundly frustrating. This was why I've gone back to my college to try and help them become more productive and relevant. That's a whole story in itself, but I'm making progress—and so is my college.

I was out of college two years before I discovered self-teaching through reading. Since then I've built quite a library. I've probably averaged a book or two a week for the last 40 years, plus at least 25 magazines a week.

It's exciting to learn. Suddenly grasping a new concept brings a rush . . . a thrill. For instance, my recent adventures in digital audio have been fantastic—it's a whole new technology. Do you understand 1-bit technology? Why not? If you have the time to watch a basketball game, you have the time it takes to understand 1-bit technology. The ball game Is soon over and forgotten. The understanding of a new concept will be with you for life. And yes, of course it can be important to amateur radio.

If we're able to keep some of our ham bands through the next couple WARCs, we're going to eventually go digital, complete with data compacting systems we haven't even thought of yet. Have you read much about data compacting technology yet? How about fractal math and chaos theory and their applications to communications?

For instance, you CW fans who are used to bleeping away at each other at a snail's pace, has it ever occurred to you to strive for more throughput? One creative approach might be to take the "Q" code concept to the next level of abstraction. A study of amateur communications will, I suspect, show that it'd be simple to develop a ham oriented "Pidgin English." We could encode the few dozen basic communications concepts we have settled into using into a simple code. Instead of sending "QSL?" we could substitute one 8-bit character for the four we've been using. Eight bits gives us 256 different combinations, so with just one character we could convey 256 different ideas. That's more than we use in a week of average ham contacts and it increases our throughput four times. This, in turn, will allow us to use only 25% as much bandwith, allowing four times as many QSOs in a band.

If you feel that's too limited then, heck, let's blow it right out to 16 bits and have 65,536 concepts. That's more concepts than I've heard discussed over the air in 20 years. But it would be a simple way to cover a wide range of ideas in a hurry and get beyond the "please QSL" contact limitations.

Several readers have written, asking how they can uncover mutual Interests during contacts. Using our present system it ain't easy. How would I be able to find out if the chap I'm talking with is into skin diving? Photography? Cooking? Miatas? Gaia? Cosmology? UFOs? Macintoshes? South African folk music? Roller coasters? Or that he's been to Bali, Cairns, Xian, or Kota

Kinabalu? A bit of encoding could compress each of thousands of interests into one single 16-bit datum.

Upon making contact, the other chap could send his name and location, followed by a string of interest codes. It doesn't take much computer power to tell me which fits in with my interests. And off we go.

Of course if you really insist on making this compatible with smoke signal technology, we could stick to our typewriter characters and send them via Morse's code. With 26 letters and 10 numbers we have 36 characters at hand. Three characters would give us 46,656 combinations. Will that hold you? We could even call it a "Q-code" if we initiated the code groups with a "QQQ" starting sequence. I doubt that we'll be wasting spectrum space with Morse code for much longer—unless of course we keep our present bands and we are unable to generate any more growth than we have in the last 25 years, in which case we can continue happily with our antique communications modes for years.

Many years ago I suggested we build a 65,000-word dictionary and assign a number to each word. Then all we'd have to do is send a string of numbers and our computers would translate them into words again for us. This would increase our throughput by three times and allow us to narrow our bandwidths by that.

A couple of added advantages would be that this would, for the first time, allow foreign amateurs to talk with us via computer-translated messages. Also, if we want security all we have to do is scramble those 16 bits around in a predetermined way. At a 9,600 baud rate we could have a throughput of around 25,000 words per minute. A 400-word message would zip through in one second.

Let's say that I've piqued your imagination and you've decided that you are willing to take the initiative and learn about some new phase of amateur radio. How are you going to go about it? Well, if you have a solid set of *73* and *QST* back issues, you've got a good start. Then you'll want to look for specialized ham newsletters to take you to the next phase.

That's what got me into this whole publishing mess in the first place. I was enjoying RTTY pioneering and got fed up with the lack of information, so I started a newsletter in 1951. It's obviously gotten way out of hand.

Alas, only a few of the hams involved with developing new technologies have enough interest in helping others to bother writing, so information is not easy to find. In the early days of repeaters there were some marvelously well-developed repeater networks such as the Gronk Network, which provided instant communications from San Diego to San Francisco and all the way out to Phoenix. I pled with them to encourage other similar nets to be developed around the country by writing. Too much trouble. I tried everything I could to get them to write. Part of the problem was laziness, part a smug protection of what those involved had learned. An unwillingness to share with others.

If you'd like to help, there are some easy ways to do it. For instance, there are tons of electronics and communications books in print. Unfortunately, many are poorly written and are not nearly as helpful as they might be. So, when you find a book you think will help others learn about some aspect of electronics or communications, how about taking a few minutes to review it? If you can let me know what you've found, I can pass this along and everyone will benefit—and we may even add it to Uncle Wayne's Bookshelf.

By focusing attention on the better books, we'll help discourage publishers from flooding us with drek. And by helping the better authors to be rewarded we'll end up with more good books. Make sense?

One of the reasons I knew *Byte* was needed was that when I read the available computer books I discovered they were almost impossible to understand. Instead of putting this down to me being dumb, I decided it wasn't me and that the microcomputer, which had just been invented, would bring about an enormous demand for easy-to-understand information. So I started magazines to fill this need. Wow, was I right on that one!

I read a book or two a week. A few of them I would love to recommend. If you're interested I'll try to keep you abreast of my reading. This would be better via our *73* BBS than in the magazine since only a small percentage of my reading is ham oriented and I suspect that most *73* readers are interested only in amateur radio oriented books and could easily turn nasty if i suggest reading anything beyond this narrow field.

But let's just suppose that you are 20, 40 or even 60 and reading this. At 20 you're just getting started in life. You're probably about to graduate from college after 16 years of third-rate education. You are undoubtedly one of the more fortunate graduates in that you are able to read and you have an interest (hamming) which you can parlay into a career. Of course you're going to have to make a big decision. You're going to have to say, "Enough with all this school nonsense, I've got to start really learning."

Of course if you get sucked into wasting your life on non-career sidetracks such as politics, religion, and righting an almost infinite number of the world's wrongs; or you let peer pressure get you involved with drugs such as alcohol, cigarettes, and worse; or you get involved with watching sports events, others are going to quickly pass you by and you're going to have to be satisfied with being jealous of those with successful careers and angry at yourself for screwing up.

At 20 you can pick any branch of electronics and within a year become an expert. Or you can coast through life waiting for a lucky break or a state megabucks win. But since you're not going to be tuned into passing opportunities, you're going to miss most of 'em.

At 40 you're having to face up to how dumb you were at 20 not to invest your time more productively. This is when men make mid-life changes. It's your last big chance to get on a personal career path which leads somewhere. It's your last chance to shape up and get the education you were too busy to bother getting at 20. Well, I'm sure those hundreds of ball games you've watched will comfort you in your old age. . . which is now looming immediately ahead of you. Forty *is* middle age. After 40 it gets increasingly difficult to find work. And it's difficult to down-size your lifestyle if the axe falls and middle management at your company is suddenly cleaned out.

At 60 you're very unlikely to ever get another job. You're on your own now. Have you stored up enough money to coast the rest of the way, golf clubs in hand? Have you enough on the ball to make a living as a consultant?

At 60 you've got a good chance at 20 more years (unless you smoke), so there's still time to start from scratch and become an electronics expert in some field. I started over when I was 61. Well, yes, I had a little money put aside to scratch with. At 61 I picked an entirely new field and began to build a new publishing career in the digital audio and music fields.

In my early years I didn't really plan. I took what came, moving from radio to TV broadcasting, then to speaker manufacturing, with side trips into psychology and music. I think my first major career decision was when I was 38 and started *73*. I knew that was a long-term decision.

My second decision was, as I said, at 61. Both turned out to be good decisions. Today I have plans going out for the next 20 to 30 years—probably far beyond my life expectancy. I'm glad I learned to learn when I was 28—and regret the years I wasted before that.

It's no news flash that education is the key to success in any way you want to measure it. I'm not talking schools, because you can educate yourself far better and faster than any school I've seen or heard of. And you can have more fun doing this than watching football or hanging out at the mall. And that's at any age from around 10 until you finally get that coveted Silent Key award plaque.

If you haven't gotten into packet yet, that's both an easy and fun way to start expanding your technological horizons. Keep notes of your progress and let me know how it goes.

License Growth

The FCC numbers are in for 1990, and if you don't mind ignoring that the FCC doesn't take into consideration dropouts and silent keys any more (since 1984), we've had some growth. If you factor in lost souls and the Grim Reaper, it doesn't look all that wonderful.

If we don't count our losses and we compare the 1990 count against 1987, we find that in four years the number of Generals has grown a mighty 4.7%. Yep, in four years and not counting losses! It's no better for Advanced, which on paper has grown by 4.2%. Wow!

Well, how about Novices? No great number of deaths there, though we can expect heavy dropouts. On paper, in four years our Novice ranks have increased by 13.1%.

Correcting the presently completely spurious FCC numbers depends on how fast we're dying off. If the average ham age today is around 55, then on the average we've got maybe 25 years left before we get our coveted Silent Key award from the League. Let's see, 25 into the FCC total of 500,000 would give us a departing rate of around 20,000 a year. No wonder those lists in *QST* are so long these days! If that's true, and not even counting dropouts, we've barely broken even in the last four years.

Settling the Arab-Palestinian Problem

Oh, good Lord! Now Wayne's going to try and settle the unsettleable. Obviously there is no simple solution to the Arab-Israeli mess. Or to the problems in Beirut, Libya, Iraq and so on. Perhaps it isn't as difficult to come up with a long-lasting peaceful solution as everyone seems to think.

So what's this got to do with amateur radio? It actually does have a good deal to do with it, though I wouldn't let that stop me from writing about it, even if it didn't.

When I first visited Jordan in 1970, I'd already been writing about the critical importance of technology to the progress of a country in my *73* editorials for several years. Amateur radio, I felt, was one of the simplest ways of introducing technology to the public. Through a hobby such as amateur radio, where learning technology is made fun, I believed that youngsters could be encouraged to become technicians, engineers and scientists. One of the main goals of my 24-country, around-the-world DXpedition trip in 1966 was to see if I could get the ITU to embrace amateur radio as a means for developing an interest by youngsters in technology in third world countries.

My first step was to visit the recent ITU ex-Secretary-General in Addis Ababa and ask his advice on how to get the ITU to encourage the growth of amateur radio in third world countries. He loved the idea and said he would make arrangements for me to meet the new Secretary-General on my visit to New Delhi.

He was as good as his word, so when I got to New Delhi I had no trouble in meeting with the new ITU Secretary-General. He too liked my plan for getting amateur radio going in third world countries as a way to introduce youngsters to the hobby. . . and to technology as a result. I promised to provide a set of amateur radio rules and regulations for the ITU to recommend.

I had a wonderful time DXing from Beirut, Damascus, Tehran, Kabul, New Delhi, Katmandu, Singapore,

Noumea, Suva, Apia, Pago Pago, Papeete and on around the world. When I got back I got to work on writing ham rules for third world countries. About this time the Secretary-General had a heart attack and died.

With amateur radio in the middle of the "Incentive Licensing" disaster, I was unable to leave my magazine and meet the new ITU Secretary-General. How bad was the hobby hit? 85% of the ham dealers had just gone out of business. 90% of the manufacturers had, too. My business manager stole all the money he could while I was on my trip and tried to put the magazine out of business so he could start his own magazine. It was a difficult time for me.

By 1970 I was finally able to get away from the magazine for a couple weeks, so when I heard that King Hussein was interested in amateur radio I saw an opportunity to give my third world country concept a try. I sent him a cable offering to help him with his new ham station. He said sure, come on over.

I spent two weeks operating JY1 from the royal palace and talking with His Majesty. I explained the benefits of amateur radio to Jordan. i pointed out that if he set up ham stations in his schools and encouraged Jordanian youngsters to learn about amateur radio, that in short order he'd have a bunch of enthusiastic electronic experts, technicians and scientists.

He gathered his government around a large table so I could explain the idea to them. I pointed out that if Jordan was going to fit into the modern world, it had to have technicians and engineers, and the best way to get them was to interest youngsters in a technical hobby such as amateur radio so they'd learn under their own steam.

When I got back home I updated my ITU amateur radio rules and regulations proposal, printed a few hundred copies on my offset press, and sent them to His Majesty. They used them pretty much as I proposed them.

Soon after I left Jordan a civil war broke out between the PLO and the Jordanians. Even though the country was in the middle of a civil war the school club stations were established and radio clubs formed.

In 1973, when I'd just finished a slow-scan QSO with a chap in Athens, a voice broke in on frequency, "W2NSD. this is Juliet Yankee One." It was His Majesty and he wanted to meet me in Washington in a few days. I met him at Blair House and was handed round-trip tickets to Amman. "I want you to see what you've done for us," he said.

When I arrived in Amman I was met by Hisham Ansari JY4HA, who proceeded to drive me from one end of Jordan to the other, introducing me to over 500 newly licensed Jordanian youngsters. They had set up one or two radio club stations in every city in Jordan.

Hisham had been appointed by the king to travel around the country to help the youngsters learn radio and electronic theory. His enthusiasm and teaching style had helped make learning fun for the youngsters.

They threw lavish parties for me and I got to meet all the top people in the government. I was a hero, at least for a few minutes. That was nice, but the real kick was that my idea had been proven. Now what could I do to get other countries to accept the idea?

Little did I know that two of the worst traumas of my life lay immediately ahead. I've shared those at length in my old editorials, so I'll save their retelling for my memoirs. By 1975 I was deep into computers, so it wasn't until 1983 that I had another opportunity to visit Jordan.

During that short visit, Prince Raad JY2RZ organized a special meeting of the Royal Jordanian Amateur Radio Society and introduced me as having had more of an influence on Jordan than anyone other than the king himself.

Okay, now let's dig into history so I can put the next step into perspective. Those of you who have any familiarity with history know that the Arabs were the world leaders a thousand years ago in philosophy, medicine, astronomy and technology.

"The solution to the Arab-Israeli problem, to the fighting in Beirut and to Syria's belligerence and all the other Arab infighting, lies in education."

The Arabs know this and it is galling for them to have been left behind by the industrial revolution and then, as a result, be exploited by the Europeans. It was technology that enabled the Jews to found Israel in 1948. They'd set up amateur radio stations all through Palestine while it was under British control. Then, when the British pulled out, these ham stations instantly became a military communications system that enabled the Jews to quickly rout the Palestinians. Indeed, amateur radio has been given a great deal of credit for the founding of the Jewish state.

The key to solving the Palestinian problem doesn't lie in distributing territory. That isn't going to solve the basic enmities which will continually erupt in confrontations. That isn't going to ease the frustrations that have built up for the last 43 years and that were exacerbated by the 1967 six-day war and the 1973 war with Egypt.

How About Japan?

Japan tried using their army and navy to gain power. We beat them with technology. Yes, we fought hard, but it was technology that won that war, not just fighting. I was right there up front in a submarine sinking Japanese ships (we sank 27 of 'em), so I know what an enormous difference technology made.

We were able to go unobserved right through the middle of Japanese convoys at night on the surface. I knew where every ship in the convoy was and every move they made, while they didn't have a clue we were there until our torpedoes started exploding all over the place.

After the war the Japanese figured out how critically important technology was and they went after it with a vengeance. Today they're far ahead of us (and the rest of the world) in many high-tech fields. Technology has made Japan #1 in the world in finance. It's enabled them to beat us (and Europe) in one industry after another.

Look at the difference technology has made in warfare. Iraq was outfitted with the latest in technology from France, Germany and the USSR, yet our weapons quickly knocked 'em for a loop. We were one generation ahead in technology and that made all the difference.

What Next, Then?

The solution to the Arab-Israeli problem, to the fighting in Beirut and to Syria's belligerence and all the other Arab infighting, lies in education. With education the Arabs will be able to come up to speed in technology and regain their racial pride.

One of the dumbest moves the blacks made in South Africa was that when they got mad at the whites, they pulled their children out of school. They stopped their education. Talk about shooting themselves in the foot! That just made a lousy situation all the worse, leaving an educational vacuum which could take generations to repair.

Now, back to Jordan. My suggestion is to start with educational programming on the Jordanian TV stations. These programs should be made so interesting that people will watch them because they're entertaining, not because they're educational.

In addition to everything normally taught in grammar school, I'd also include a course in the fundamentals of electronics, computers and communications. I'd encourage the youngsters to start electronic experimenter clubs, radio clubs, computer clubs, science fair clubs and so on. I'd encourage the youngsters to get together to help each other learn more about all kinds of scientific things.

If Jordan is going to cover everything, it'll take several TV stations, and the people will need VCRs to tape courses broadcast at inconvenient hours. Once broadcast, the tapes can be made available for home rental.

There is nothing at all the matter with Arab intelligence. They just need education and they'll give the rest of the world a good run for their money. The method I've described would provide this education at the lowest possible cost. It also wouldn't be held up for 10 to 20 years while new teachers are trained.

A few Arab countries have oil, but most have little more than their people as a resource. Educated, they can be the most valuable resource in the world. Uneducated, they are likely to be frustrated and thus easily gulled by fanatics. When we see screaming Arab mobs, we know we are not looking at educated people.

Japan has shown how it's done. We're learning many things from them. Perhaps the Arabs can too. Japan has well over a million licensed amateurs so far. The Arab countries, what, dozens? Outside of Jordan, I doubt it.

If they start teaching science to Arab youngsters we may start seeing hundreds of thousands appearing on our bands. Then, if we've decided to use amateur radio to actually talk with people instead of coercing QSL cards out of them for DXCC credit, we may finally have people-to-people communications and start building friendships.

Yes, I make it sound simple. I think it is. I'd like to see His Majesty King Hussein start providing education for his people and the nearby Palestinians in Israel. Then, via educational video tapes, Jordan can become the education center for the entire Arab world.

Science teaching will go much faster if the video courses are supported with good textbooks and science labs. I've some inexpensive, creative solutions to these needs too.

No, you can't force people to be educated. We've certainly proven that here in the U.S, where our compulsory system is a world class failure. But you can make it so much fun that kids learn because they enjoy it. And the more they learn, the more successful they'll be as a people and the wealthier their countries will become. And this can be done in one generation.

We've seen this in microcosm in amateur radio. No one forced us as kids to learn radio theory. We did it because we wanted to, because we enjoyed it. And the more we learn, the more potential we have for success in today's technological world. We are no longer tolerant of computer-illiterate people in our workplaces.

If we can get the Arabs hooked on education, who knows. . . perhaps we'll even be able to sell this radical idea here in the U.S.!

Am I suggesting that it's possible to turn nomadic goatherds into rocket scientists in one generation? Yep, that's exactly what I'm suggesting.

Since this is an editorial, not a book, I haven't gone into depth with my entire plan. I thought I'd mention that just to ward off the brickbats from negative people. Let me remind you that successful creative thinkers are positive. They tend to think in terms of solutions rather than problems. Is that the way *you* think? 73

YIG Sweeper

Last month I described the YIG (Yttrium Iron Garnet) oscillator and its internal construction. I also covered a sweep ramp generator, part of the YIG sweep oscillator project. This month, I'll finish the project with the drive circuits for the YIG oscillators. The sweep ramp generators tie directly into the driver circuits, providing both the YIG current control amplifiers and the oscilloscope with an external, horizontal drive, for full synchronization of both the YIG oscillator and oscilloscope.

The sweep ramp generator has controls for ramp symmetry and sweep length. The 1458 op amp operates from a +15 and −15 volt power supply. This is necessary because of the need for a wide swing between both power supply rails. Sweep ramp voltages for this op amp vary from +14 to −14 volts.

The power supply requirement is +15 volts at 1 amp. The negative supplies do not need to be high current regulators. Two are required: −5 volts and −15 volts. If your YIG is an HP type, you will need to add a −10 volt regulator.

Before I get into the drive circuit I thought I would provide you with some details on other YIG pinouts that I have run across. I don't know if you can locate the same type I have, but the information should prove helpful. For the Hewlett-Packard 2–6 GHz YIGs, power goes to a 14-pin DIP socket on top. Pin 1 is ground, pin 3 is +20 volts, pin 6 is −10 volts, pin 10 is the main coil positive terminal and pin 11 is main coil negative. The 3.8 to 6 GHz HP YIG pinouts are the same, with the addition of pin 14 being the FM modulation drive input pin.

John W7HQJ, who designed these driver circuits from multiple sources, is happy to share this project with the experiment-oriented amateur. The circuit is as simple as possible, while still making a very useful YIG sweeper/driver.

Circuit Description

Op amp U1a, an isolation amplifier in the sweep output, couples into the summing amplifier, U1b. U3a, another isolation amplifier, is in the voltage divider, the center frequency control. The high and low limit potentiometers there are relay-selected in each of the three different frequency ranges.

The details of multi-YIG switching aren't in the schematic. U2 and Q1 are the YIG driver current source, with Q1 connected as an emitter follower. This increases the current driving capability of U2 to the high values most YIGs need. The current limiting resistor in the emitter lead (25 ohms) is suitable for YIGs drawing about 180 mA. You need a 10 ohm resistor for 800 mA YIGs.

The comparator U3b serves as a fail safe should the operator turn the center frequency controls too high for the YIG. It samples the voltage on the wiper of the center frequency control, and when the voltage exceeds the desired threshold, it's directed to a high value current limiting resistor. Everything stops until the center frequency potentiometer is returned below this threshold.

Construction is straightforward. You can use perf board. In the future I may do a PCB layout for the circuit. It's my way of doodling in my spare time.

The leads for the YIG oscillator should have ferrite beads slipped over each end of the magnet driver coil leads. And, if you want to do CW operation, you need to put a large capacitor across the coil, to swamp out coil resonance. Keep the power supply leads short and well-bypassed. I usually grab a handful of 0.01, 0.1 and 10 µF capacitors, and sprinkle them around generously to minimize stray signal interference. It's a cheap fix. Rather than trying to find the lead that's making trouble, I bypass all the leads.

Mailbox Comments

The Ventura ARC wrote me of their latest laser QSO. Dick WA6JOX at Pumpkin Center and Steve WA6EJO at Mt. Pinos, California, 32 miles apart, easily pointed the laser at each other after determining accurate locations with 10 GHz "beam" headings. The laser receiver was constructed out of 4-inch PVC pipe with a front lens and a C7138 photomultiplier for the laser light detector. Dick stated that flashing spotlights in the direction the X-band signals came from helped, and he could easily see the bright light on Mt. Pinos; but the crew on Pinos had difficulty sorting out his spotlight from nearby city lights.

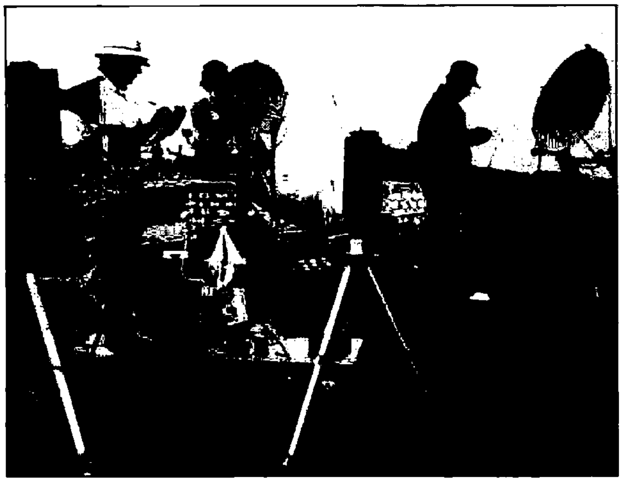

Photo A. Some members of the San Diego Microwave Group during the 1990 10 GHz contest on Mt. Soledad. Left to right: John WB6BKR, Kerry N6IZW, and Chuck WB6IGP. Photo by Bert K6BTO.

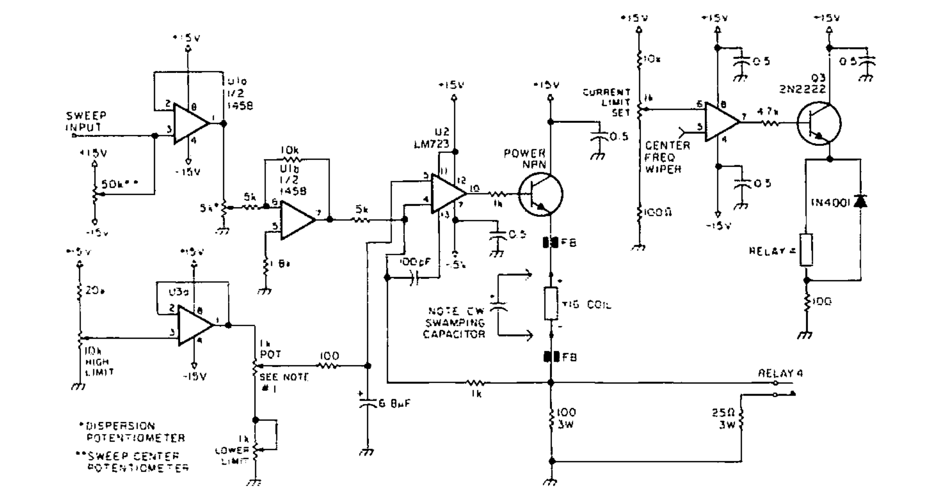
Aimed at each other, the lasers were bright even at 32 miles distance. Very little flicker from atmospheric disturbance was noted. The lasers used were 2.5 mW, HeNe (helium neon) which operate at a frequency of 474 THz, or, if you prefer, *474,000 GHz*! Quite an accomplishment.

Jack VE4JX is putting an IF and 10 GHz wideband system together using parts of an Alfa burglar alarm system. As microwave materials are scarce in Canada, he needed help obtaining parts. Using the *RSGB Handbook*, Jack is constructing a Gunn cavity.

Got to apologize to Paul KØIWA. I sent him a kit for the 30 MHz IF amplifier ("10 GHz Fun" in the April 1990 issue). The problem was I forgot to include the PC boards. Must have had toooo much sugar in my coffee that morning. By the way, Paul's call is especially great for an amateur living in IOWA.

Steven of Steven Coakley Video Microwave Services, referring to my August 1990 column, says it can be simple to receive commercial microwave transmissions. All you need is an SSB communications receiver. After tuning in, you demodulate the video output of the microwave receiver. A similar system is used in satellite communica-



Note 1: Center frequency control. You can select three YIGs for different frequency ranges by individually selecting them via relays along with different high and low limit pots. The schematic shows the hookup for just one YIG device.
Note 2: Relay 4 is normally closed. If the current goes too high (actuated by the comparator from the center frequency control) the relay drops out to provide a higher value of YIG current-limiting resistance.
Note 3: Bypass all IC power leads with 0.5 µF capacitors to ground.

Figure. The spectrum analyzer driver and out of range current limiter; John Petrich W7HQJ, 9/90.

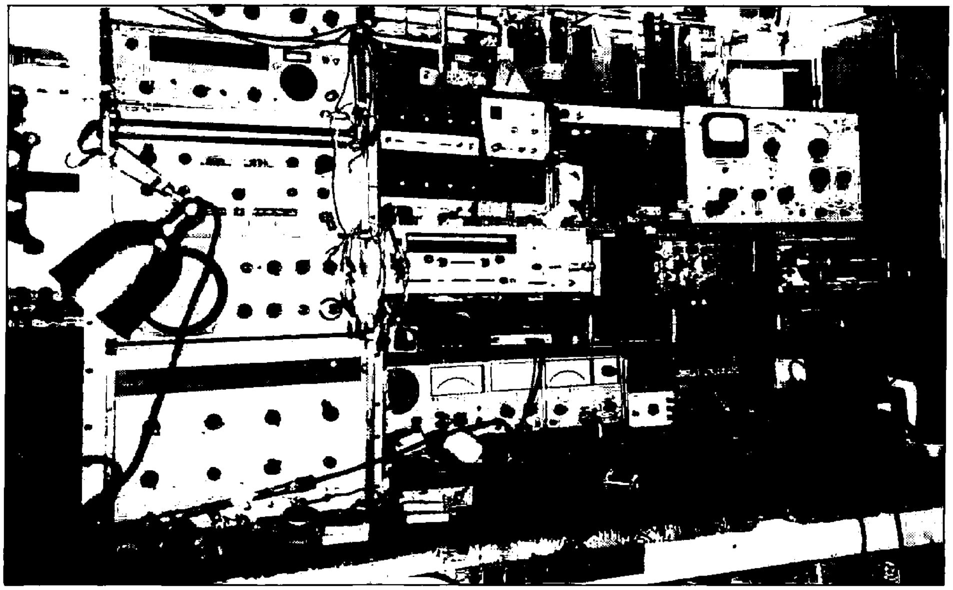


Photo B. WB6IGP's work bench, always cluttered, always changing.

tions to send long distance calls.

The video has all the SSB channels stacked from about 20 Hz to about 8 MHz. Steven suggests the book, *The Hidden Signals on Satellite TV*, by Thomas P. Harrington and Bob Cooper Jr., available from Howard Sams Publishing or through "Uncle Wayne's Bookshelf."

Well, Steven, if the signals are analog in nature, you can receive them. This scheme is used to transmit and receive microwave voice channels. I did a poor job of trying to explain analog and digital. Analog systems seem to be in decline, with most systems going digital. Digital format makes reception dependent on a digital terminal of similar type. There are test sets to do this, but none yet in surplus.

Myron KA9THG liked the switching power supply article in the August 1990 issue, and thanked me for helping him solve a problem. He had been looking for a simple way to run his printer on 12 volts DC. He had a bushel of old CB power supplies, and would you believe, the transformer he found is just what the doctor ordered—110 primary and 24 volts secondary. One thing: Watch out for spiking on the drains of the FETs. I used a series 0.1 μF capacitor and a 5 ohm resistor to minimize spiking. The formula for circuit frequency is TC = 4.40 times (R • C), or TC (60 Hz) = 4.4 • (38k • 0.1 μF). In actual tests, some variations in the capacitor suggest slightly higher values (+0.01 μF) to trim to proper frequency.

Alva KD4BH also wrote to me about this article, wondering why I didn't include a schematic. Well, Alva, I just forgot to send it in for that column. See the *Updates* section in this issue for the schematic.

That's it for this month. Next month, with the help of Steve WA6EJO, we'll explore laser communications. As always, I will be glad to to answer any questions related to our VHF/UHF microwave bands. Please send an SASE for prompt reply. 73's Chuck WB6IGP

SPECIAL EVENTS

Ham Doings Around the World

Listings are free of charge as space permits. Please send us your Special Event two months in advance of the issue you want it to appear in. For example, if you want it to appear in the January issue, we should receive it by October 31. Provide a clear, concise summary of the essential details about your Special Event. Check /HAMFESTS on our BBS (603-525-4438) for listings that were too late to get into publication.

MAY 4

OSWEGO, NY The Southern Tier ARC will host the Southern Tier Hamfest from 8 AM-4 PM at Marvin Park Fairgrounds. 32nd Annual Banquet, VE Exams, Flea Markets. Tickets are $3 in advance, $4 at the gate. Tailgating $2 extra; tables $15. Banquet (includes general admission) $18 per person in advance. Contact *STARC, PO Box 7082, Endicott NY 13760*. Talk-in: 146.16/.76 or 146.52.

CEDARBURG, WI The Ozaukee RC will sponsor the 13th annual Cedarburg Swapfest from 8 AM-1 PM, at the Circle-B Rec. Center, Highway 60 & County I. Advance tickets $2, $3 at the door. 4' tables $3. Set-up at 7 AM. License exams start at 9 AM. Talk-in on 146.37/.97 and 146.52. For reservations and info, send an SASE to *ORC Swapfest, 11448 Laguna Dr., Mequon WI 53092. (414) 242-4995.*

BEMIDJI, MN The Paul Bunyan ARC will hold its annual Hamfest from 7 AM-3:30 PM at the Moose Lodge. VE Exams. Talk-in: 146.13/.73. For info call or write *Don Ilies NØMAZ, R.R. 2 Box 187AA, Bemidji MN 56601. (218) 751-9254.*

MAY 4-5

ANDERSON, SC The Blue Ridge ARS will sponsor the Greenville Hamfest/Electronic Flea Market at the Anderson County Fairgrounds from 8 AM-5 PM Sat.; 8 AM-3 PM Sun. Walk-in license exams. Camping, free parking. Set-ups with advance registration. Advance tickets $4, $5 at the gate. For tickets, info, send SASE to *Blue Ridge ARS, PO Box 6751, Greenville SC 29606.*

SIERRA VISTA, AZ The Cochise ARA will hold its annual Hamfest at the club training facility, 5 miles east of town on State Rte 90, then 2 miles south on Moson Rd. All ham radio, computer and related businesses are invited. Free tailgating. VE Exams. Overnight RV camping for club members (no hookups). Facilities for the handicapped. Talk-in: 146.52 or 146.76 (−.6). Contact *N7INK (602) 378-3155* after 6 PM, or write to *CARA, PO Box 1855, Sierra Vista AZ 85636.*

MAY 5

SANDWICH, IL De Kalb Hamfest, sponsored by Kishwaukee RC, will be held at the Sandwich Fairgrounds, beginning at 8 AM. Set-up at 6 AM. Overnight camping, no hookups. Tickets $4 in advance with 2 stubs. After Apr. 15th, and at the gate, $5. Tables $10 each. Tailgate space free with paid ticket. Talk-in on 146.13/.73 and 146.52. For reservations, make check payable to KRC and send with an SASE to *Howard Newquist WA9TXW, PO Box 264, Sycamore IL 60178.*

ALEXANDRIA, VA Fairfax Computer Fair/Flea Market will be sponsored by the Thomas Jefferson High School for Science and Technology PTSA, in conjunction with the Capital PC User Group. The proceeds will go to benefit computer oriented education. This event will be held at the Thomas Jefferson High School from 9 AM-4 PM. Contact *Mark Bakke, (301) 530-1303* or *Mort Rau, (703) 754-9859.*

ST. PETERSBURG, FL The St. Petersburg ARC will sponsor a Hamfest at Lake Maggiore Park from 8AM-3 PM, rain or shine. Free parking. No tailgating. VE Exams from 10 AM-2PM. Admission $4, kids under 12 free. Set-up at 7 AM. For registration: *Otto Suplski WB2SLO, (914) 969-1053.*

YONKERS, NY The Metro 70cm Network will hold a Giant Electronic Fleamarket at the Lincoln High School from 9 AM-3 PM. Free parking. VE Exams from 10 AM-2 PM. This is one of 3 Giant Electronic Flea Markets. The other two will be on Sept. 29th, 1991 and Jan 19th, 1992. Sellers can get ½ price by registering for all three events and paying the full amount in advance. Deadline dates are 5/3/91, 9/10/91, 1/8/92. Registered tables $15 for the first, $10 for each additional. Bring your own table at $1.80 per foot. $10 minimum. Tables $20 at the door, $2.50 per foot. Reserved tables and space will be held only to 9 AM. No refunds without notification of cancellation 72 hours in advance of each event. Admission $4, kids under 12 free. Set-up at 7 AM. To register, call *Otto Supliski WB2SLO, (914) 969-1053.*

MAY 11

MANITOWOC, WI The Mancorad RC will hold its annual Hamfest from 8 AM-5 PM at the Manitowoc County Expo Ctr. Flea Market (amateur, computer, SWL). VE Exams. Advance tickets $2, $3 at the door. 8' tables $3, with electric outlet $8. SASE to *Mancorad RC, PO Box 204, Manitowoc WI 54220.*

SPRINGDALE, AR The Northwest Arkansas ARC will hold "HAMFEST 91" at the Rodeo Grounds Community Building from 8 AM-4 PM. Free admission. Tables $5 each, advance registration required. Tailgating $4 per vehicle. Free parking. Talk-in on 146.76 (−.600). Contact *Jim Henington KB5ITL, PO Box 278, West Fork AR 72774. (501) 839-2488 after 4:30 PM. Via packet KB5ITL @ KA5BML.AR.USA.*

MAY 12

ATHENS, OH The Athens County ARA will hold its 12th annual Hamfest at the City Rec. Center from 8 AM-3 PM. Admission $4 per ham, spouses allowed in free. Free Tailgating space. Indoor space by advance registration only. For info write to *Carl J. Denbow KA8JXG, 63 Morris Ave., Athens OH 45701.* For registration contact *John Biddle WD8JLM, 80 Wonder Hills Dr., Athens OH 45701. (614 594-8901 after 6 PM.* Talk-in: 145.15/.55 MHz.

MAY 18

FORESTDALE, RI The Rhode Island Amateur FM Repeater Service, Inc. will hold their annual Spring Auction and Flea Market at the VFW Post 6342. The Flea Market starts at 8 AM, spaces are $5 each. The Auction will be from 11 AM-3 PM. Free admission. Talk-in on 146.76. Contact *Rick Fairweather K1KYI, PO Box 591, Harrisville RI 02830* or call *(401) 568-0566* between 7-8 PM.

EPHRATA, PA The Ephrata Area Repeater Society, Inc. will hold the Lancaster County Hamfest at the Ephrata Senior High School beginning at 8 AM. Set-up at 6:30 AM. Handicap accessible. Admission $4, Tailgating $3, Tables $6. Talk-in on 145.45, 146.52 and 444.65 MHz. For info/reservations contact *Tom Youngberg K3RZF, (215) 267-2514* after 6 PM, or write, *E.A.R.S., 906 Clearview Ave., Ephrata PA 17522.*

DEWITT, IA The Clinton ARC will hold "HAMFEST 91" at the 4-H County Fair Grounds starting at 8 AM. Set-up at 6 AM. Over-night security. Talk-in: 147.06 and 145.430. VE Exams start at 9 AM. ATV and DX packet cluster seminars. Contact *Darryl Petersen KDØPY, RR1 Box 84, Bryant IA 52727.*

CADILLAC, MI The Wexaukee ARA will sponsor their annual Swap and Shop at the Cadillac Middle School from 8 AM-1 PM. Admission $3., tables $6. Talk-in on 146.38/.98 repeater. Contact *Dan Schmidt KE8KU, (616) 775-0998*, or write, *Wexaukee ARA, PO Box 163, Cadillac MI 49601.*

MAY 19

WABASH, IN The Wabash County ARC will hold its 23rd annual Hamfest at the Wabash County 4-H Fairgrounds from 6 AM-4 PM. Free overnight camping. Advance tickets $4.50, $5 at the door. Amateur exams will be given for Tech-Extra by the North Central Indiana Examiner Team from 8 AM-Noon. Talk-in: 147.63/.03, 148.52/.52, 146.94/.94. For ticket info send SASE to *Don Spangler, 235 southwood Dr., Wabash IN 46992. (219) 563-5564.*

PEOTONE, IL The annual Hamfest sponsored by the Kankakee ARS will be held at the Will County Fairgrounds from 8 AM-2 PM. Set-up 6 AM-8 AM. Free parking. Overnight RV parking, no hookups. Advance tickets $3.50, $4 at the door. Talk-in on 146.34/.94. Contact *KARS, C/O Frank DalCanton KA9PWW, 117 Kristina Dr., Bourbonnais IL 60914. (815) 932-5950 after 7 PM CST.*

MAY 25

DURHAM, NC The Durham FM Assn. will hold its 18th annual "DUR-HAM-FEST" under the south parking deck of the South Square Mall shopping center. Wheelchair accessible. VE Exams contact: *Pete Goolsby KY4Y, 120 Radcliff Circle, Durham NC 27713, (919) 544-3215.* Advance tickets are $4, $5 at the door. Please SASE with your order to *R.P. Buehlmann N4IQA, 1314 Chaney Rd., Raleigh NC 27606. For table info and registration contact* Thomas D. Ferrell WA4MWT, 3012 Glendale Ave., Durham NC 27707, (919) 220-5018, *or* Sid Edwards W4QWM, 1700 High St., Durham NC 27707, (919) 489-2933. *To reserve space and advance tickets, contact Sid Edwards W4QWM, (919) 489-2933 before 9:15 PM.*

MAY 26

WEST FRIENDSHIP, MD The Maryland FM Assn. will sponsor its annual Memorial Day Hamfest (for amateur radio related items only), at the Howard County Fairgrounds from 8 AM-3 PM (premises must be cleared by 5 PM). Talk-in on 146.16/.76, 223.16/224.76 and 449.00/444.00 WA3DZD repeater. Donation $4, tailgating $3. Tables $15 in advance, $20 at the door (if available). Only PAID table reservations accepted. Make checks payable to MFMA, Inc., and SASE to *Melvin Seyle WA3KZR, 15809 Pointer Ridge Dr., Bowie MD 20716, (301) 249-6147.* Commercial vendors must have proper tax/license certificates available. All proceeds will be used to improve the Club's repeater system.

CHICAGO, IL Chicago ARC will hold the annual Hamfest at De Vry Inst. of Tech., from 8 AM-3 PM. Set-up at 6 AM. Tickets $3 in advance, $4 at the door. Write to *CARC, 5631 W. Irving Park Rd., Chicago IL 60634.* Or call *(312) 545-3622.* Talk-in 147.225 +600 PL.

SPECIAL EVENT STATIONS

MAY

VERMONT Throughout the year, Special Event Stations from Vermont will be operating 25 kHz up from the bottom of the Novice and General bands to help celebrate Vermont's 200th Anniversary. RTTY/AMTOR/etc. will be in the digital sub-bands. To obtain a special Certificate, send $1 and a SASE to *Amateur Radio Bicentennial Project, PO Box 200, Graniteville VT 05654.* Foreign stations, send only SAE and IRC's, to cover postage.

MAY 3-12

SACRAMENTO, CA The California State Railroad Museum will operate WB6RVR from the Central Pacific Depot in Old Sacramento, May 3rd-May 12th, 1600-2400Z during "RAILFAIR '91," to commemorate the Museum's 10th anniversary. Frequencies: Phone 7.270, 14.270, 21.370, and 28.370 MHz. For commemorative QSL, send your QSL and No. 10 SASE to *California State Railroad Museum, Attn: Steam Trains, 111 "I" St., Sacramento CA 95814.*

MAY 4

GRANTSBORO, NC The Ol' Country Fair of Pamlico Community College will operate N4WRR from 1400-1900Z to commemorate the 17th annual Fair. Operation will be 25 kHz up from the General band edges and the Novice 10 meter phone band. Send QSL, QSO number, and SASE to *N4WRR, PCC, PO Box 185, Grantsboro NC 28529-0185.*

MAY 4

BAYONNE, NJ The Bayonne Emergency Management ARC, sponsored by the City of Bayonne, NJ, will operate W2ODV from 1200 UTC-2400 UTC on May 4th and 1200 UTC-2400 UTC on May 5th. Operation will be on all bands from 80 meters through 440 MHz, with concentration in the Novice and General class portions. Each club member will sign their own call followed by "BEMARC Special Event Station." To receive a special Certificate, send a QSL card with an 9 X 12 SASE and one unit of postage (or one IRC) to *BEMARC, c/o John Anzivino, 236 Pearsall Ave., Jersey City NJ 07305.*

MAY 10

PROMONTORY, UT The Odgen ARC will operate W7STB from Promontory Summit, to commemorate the 122nd year of the driving of the Golden Spike, from 0001Z-2100Z. Frequency will be on one of the following: 3.970, 7.270, 14.280, 21.375 or 28.415 MHz. Send QSL and SASE to *Ogden ARC, PO Box 3353, Ogden UT 84409.*

MAY 11-12

LAS VEGAS, NV The Nevada QSO Party, sponsored by the Frontier ARS, will be held from 0000Z May 11th-0600Z May 12th. Frequencies: 6 through 160 meters. Modes: CW/SSB/RTTY/SSTV/Packet. Scoring: 1 point for Phone QSO; 2 points other modes. Nevada stations multiply by state/province/country total. Non-Nevada stations multiply by number of Nevada counties. Awards: Certificates to top score of each state/province/DXCC country. Mail entry by June 1st, 1991 to *Jim Frye NW7O, 4120 Oakhill Ave., Las Vegas NV 89121.*

MAY 11-19

HOLLAND, MI The Holland ARC will operate K8DAA to celebrate Tulip Time. Frequencies: Low end of General bands on 15 and 20 meters, and 28400 on 10 meters. For Certificate, just work two HARC members or the Club station. Send QSL card with calls worked and SASE (legal size or 9 X 12) to *Dave Lamer WA8RSA, 2866 E. Chester Dr., Zeeland MI 49464.*

MAY 12-17

DAVIS MTNS, TX Amateur astronomers/hams representing the Southwest Region of The Astronomical League, will operate K5GH at the 10th annual Texas Star Party, located near the University of Texas' McDonald Observatory in the Davis Mtns., from May 12th-17th. Frequencies: (±QRM): 28365, 21365, 14265 and 7265. SSTV and CW contacts on request. For an astronomical-theme QSL card, send QSL and SASE to *K5GH-TSP, 721 White Dr., Garland TX 75040.*

MAY 18

HANFORD, CA The Kings ARC will operate AA6GZ, 1600Z-2200Z, to commemorate the Centennial Anniversary of Hanford, CA. Frequencies: The General 10, 15 and 20 meter phone and the Novice portion of 10 meters. For a certificate, SASE to *KC6HVE, PO Box 548, Armona CA 93202.*

MAY 18-19

CHICAGO, IL The DuPage ARC will operate Club station W9DUP, to commemorate Armed Forces Day. Operation will be from the U-505 submarine at The Chicago Museum of Science and Industry, Sat. & Sun. from 1600 UTC-2300 UTC. Frequencies: 7.250, 14.290, 28.400 SSB and 145.25 (−.600). For a certificate, send QSL and SASE to *Jack Carr NV9S, DARC, PO Box 71, Clarendon Hills IL 60514.*

ST CHARLES, MO The St. Charles ARC will operate WBØHSI from 1300Z-2100Z as part of the Lewis and Clark Rendezvous. Frequencies: 7250, 14250, 21350, 28410, and 146.67, as conditions permit. For 8½ X 11 certificate, send a large SASE to the *St. Charles ARC, PO Box 1429, St. Charles MO 63302-1429.*

LONG BEACH, CA The Hollywood Chapter of the Lambda ARC will operate K7OO from the site of the annual cultural pride festival, adjacent to the Queen Mary in Long Beach. Frequencies: General portions of the 40, 20, and 15 meter bands and the Novice portion of the 10 meter band. For a special QSL, send a QSL card and business size SASE to *LARC, PO Box 91299, Long Beach CA 90809.*

MAY 28

ANNAPOLIS, MD The United States Naval Academy ARC will operate the Club station, W3ADO, from 1300Z-1800Z, to celebrate commissioning week at the Naval Academy. Operation will be in the lower 50 kHz of the General and Novice phone bands. For QSL, send QSL (no SASE) to *Peter Erpelding WB6MXL, 14D Sellers Rd., Annapolis MD 21402.*

HAM HELP

Your Bulletin Board

We are happy to provide Ham Help listings free on a space available basis. To make our job easier and to ensure that your listing is correct, please type or print your request clearly, double spaced, on a full (8½" x 11") sheet of paper. Use upper- and lower-case letters where appropriate. Also, print numbers carefully—a 1, for example, can be misread as the letters l or i, or even the number 7. You may also upload a listing as E-mail to Sysop to the 73 BBS, (603) 525-4438, 8 data bits, 0 parity, 1 stop bit. Thank you for your cooperation.

I need the manuals for the Yaesu FRG-7 receiver. I will pay copy and postage costs. *Tom Francis KB5OCU, RT 2 Box 336, Leonard TX 75452. (903) 568-4698.*

I need a schematic or other printed material on a Pace FM 152 VHF transceiver. It is presently tuned to 156 MHz and I would like to retune it to the 2 meter band. I will appreciate any help I can get on this project. Also, does anyone know the address of Pace Comm. Div., or PATHCOM, Inc.? Thanks. *B.T. Jeavons WA6GEF, 5825 Cedar Rd., Ocean Springs MS 39564.*

I need a schematic and/or manual for an EICO oscilloscope Model 470. Also, a bathtub cap for same: 2X.5 MFD 1500VDC. *William R. Bogart KA9CWK, RR2 Box 50B, Covington IN 47932.*

I am looking for the manufacturer of a beam antenna. It is wound on fiberglass rods and is wound with copper tape instead of loading coils. *Pete Anderson W5VYV, 1209 W. Cochiti, Hobbs NM 88240.*

Wanted: A Model J-37 CW aircraft key for display in a WW2 aircraft radio museum. A small sign indicating the name of the donor will be placed next to the key in the museum. *Bill Pearce W0MWO, Eagles Rest, 9 Knightsbridge Place, Pueblo CO 81001-1434. (719) 544-0691.*

I would like to exchange operating and maintenance ideas with anyone still operating Hallicrafter's HURRICANE transceivers. Please contact *R.P. Paulukonis KB1TY, PO Box 321, Strafford NH 03884.*

Wanted: Teletype LPR35BWA w/LRB23 base, LMU4 motor and LBAC255BR cabinet. *Charles T. Huth, 229 Melmore St., Tiffin OH 44883 (419) 448-0007.*

The Dayton ARA is now accepting applications for the 1991 Scholarship Program. There will be eight $1500 scholarships available this year. The program is open to any FCC licensed amateur operator graduating from high school in 1991. There are no restrictions on class of license or planned course of study. For application forms and information, write to *DARA Scholarship Committee, 317 Ernst Ave., Dayton OH 45405.*

Teacher of developmentally-disadvantaged high school students would appreciate donation of books on audio and RF equipment construction and design, intended for home-brewers (no college engineering texts please). Cannot accept equipment, magazines, or books that are moldy. I will reimburse shipping at *cheapest* commercial rate (book rate, first class, or UPS). *Douglas Conley, c/o Conley Vision, 12008 W. 87 St. Pkwy., Lenexa KS 66215.*

Wanted: Operating manual (or photo copy) for the Hickok Model 752-A tube tester. I will pay all costs and postage. *Hal Smith W2GKE, 26 Linden St., Bayonne NJ 07002. (201) 436-1405.*

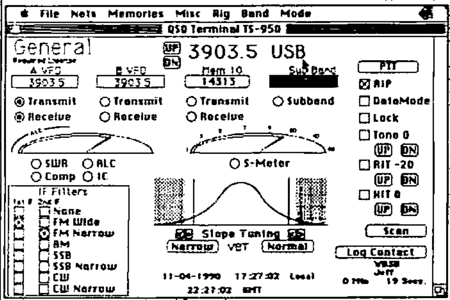
QSO Comp-Troller
PC Control for Kenwood Rigs

New!

QSO Software proudly announces a second entry in quality ham radio software. QSO Comp-Troller offers complete PC control of Kenwood transceivers. The program is available for the Macintosh and MS-DOS (IBM Compatible) PCs with >64K EGA or VGA Graphics and a Microsoft® compatible mouse. QSO Comp-Troller is currently optimized for the Kenwood TS-950 transceiver, and will control all other RS-232 compatible Kenwood radios. Major functions included in the software are listed below. (Not all Kenwood models support every function)



Actual Screen Image

- Direct Keyboard Frequency Entry
- Text notes on each Memory
- Store and retrieve Memories to Disk
- Net Frequencies, notes, modes
- Required license & band limits
- Direct terminal emulation to Xcvr
- Sub Band receiver control
- Analog Multi-function and S-Meter
- Filter control
- Enhanced Scanning
- Automatic Logging
- GMT and Local on screen clock
- Slope and VBT tuning
- Graphical user interface with pull down menus and windowing

Introductory Price $149.95

See us at Dayton - Booth 640

QSO Tutor
Study Aid for Amateur Exams

- Runs on IBM Personal Computers and compatibles or Macintoshes.
- Programs are available for all Amateur classes, Commercial Radio Telephone and Radar Endorsement. Sold separately.
- Work with the entire question pools (updated Nov. 1990), or study questions automatically selected by the program from your weakest areas.
- Includes full screen graphics & explanations on appropriate questions.
- Logs multiple study sessions and allows resuming at a later time.
- Creates randomly generated sample tests on-line or written on Epson/IBM or Macintosh graphics printers.

$29.95* per class Mac® IBM®

* PA residents add 6%. Commercial class is $39.95. Price includes shipping. Add $2 each for 3 1/2" IBM Disks

Public Domain disk also available. Contains excellent morse code tutor as well as other Ham Radio programs. Cost is $5 to cover materials and handling.

HIGH PERFORMANCE PRESELECTOR-PREAMP

The solution to most interference, intermod, and desense problems in repeater systems.

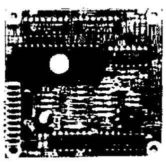
- 40 to 1000 Mhz tuned to your frequency
- 5 large helical resonators
- Very high rejection
- Low noise—high overload resistance
- 8 db gain—ultimate rejection >80 db
- GaAs fet option (above 200 Mhz)
- Cast aluminum enclosure
- N, BNC, and SO239 connector options

Typical rejection:

±600Khz @ 145 Mhz: 28db	
±1.6 Mhz @ 220 Mhz: 40db (44db GaAs)	±20 Mhz @ 800 Mhz: 65db
± 5 Mhz @ 450 Mhz: 50db (60db GaAs)	±20 Mhz @ 950 Mhz: 70db

AUTOMATIC IDENTIFIERS

- Up to 8 EPROM programmed messages
- Adjustable audio, speed & interval timer
- "ID over voice inhibit"
- Low power option
- Modular design
- Message selection via binary input—TTL levels
- Size: 2.7 x 2.6 x 0.7"



NEW Model ID-2B

The ID-2B provides required station identification without troublesome diode programming. The "ID over voice inhibit" circuitry allows for courteous operation by not allowing an ID until the next squelch closing.

ID-2B Wired/Tested $99.95 **ID-2B-LP Low Power $109.95**

Notes from FN42

Good news as I am writing the column; the fighting in the Persian Gulf has ended. I have made an effort to not write about what has been happening, but I read in a recent Wall Street Journal *that there was ham activity from Kuwait during the conflict. It will be reported under the Kuwait banner in "Roundup."*

This month's column is colorful, with pictures from the Greek climbers shown in last month's issue, the QSL card from Olimpiada Cultural Barcelona '92, a photo of Byong-Joo Cho HL5AP and his family, and letters from Rod Hallen 5Z4BH and Woodson Gannaway N5KVB/EA.

And now, on with the show!

—Arnie N1BAC.

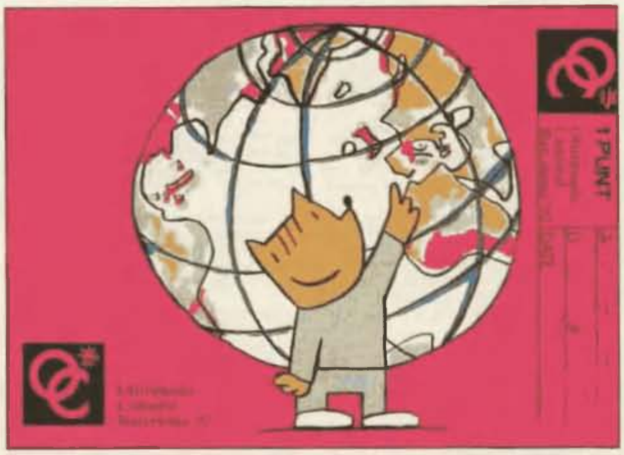

Photo B. QSL card for the Olimpiada Cultural Barcelona '92

Photo A. Our Hambassador to South Korea, Byong-Joo Cho HL5AP, and his beautiful family.

ROUNDUP

Japan From *The JARL News*: "Radio Amateur Becomes Minister of Posts and Telecommunications," reads the headline. Mr. Katsutsugu Sekiya JA5FHB, a member of the House of Representatives, was welcomed and honored as the new minister by 200 JARL members. Mr. Shozo Hara JA1AN, President of JARL, expressed his congratuations and sincere expectations for Mr. Sekiya's good role for further promotion of amateur radio in Japan.

Mr. Sekiya acquired his first amateur radio license in 1970, and he is one of the founding members of Diet Ham Club, JG1ZQU, which consists of 21 members of the House of Representatives, 1 member of the House of Counselors, and 59 members of the Diet staff.

On another note, Ginowan City in Okinawa has been selected as the site for JARL's 33rd General Assembly, scheduled to be held on Sunday, May 26, 1991.

The Annual General Assembly is that time of the year when all participating members reflect upon JARL's activities and operations, and in so doing promote mutual understanding. It is also an important meeting where the pros and cons of yearly programs, as well as the all-important budget, will be discussed and resolved, hopefully to the eventual satisfaction of all members.

Kuwait From *The Wall Street Journal*, March 4, 1991, dateline Kuwait City, Kuwait. This article describes how some of the Kuwaitis made it through the crisis by bartering food and material things.

One of the families mentioned was the "Sultans," a prominent merchant family. They asked that their real surname not be published because they fear for the lives of three family members still held by Iraq. Amiri, mentioned in the following paragraph, is a member of that family.

"In one way, the Sultans did continue to defy the occupation directly. Seated at the computer in his basement, one of Amiri's cousins, a ham radio operator, continues to this day to run one of the few communications links with the outside world. Mostly, he has sent out personal messages to Kuwaitis abroad. Several months into the occupation, the Iraqis compiled a list of hams and made a sweep of their equipment. Amiri's cousin politely greeted the soldiers at his door and handed them an antiquated piece of radio gear. Meanwhile, Amiri continued broadcasting from his basement. He also piled boxes of food at his door to distract future visitors on similar missions."

[Not every member of the "Sultan" family or other families were as lucky. Some were killed and some have been taken and not heard from since. Let us all pray that those missing will be returned safely, and that the crisis in the Middle East will be solved to the satisfaction of ALL.

—Arnie]

KENYA

Rod Hallen 5Z4BH
AMEMBASSY Box 55A
APO New York 09675

Since the 20th of September I have only spent two weeks in Kenya. The rest of that time I was in the U.S.A. or traveling in East Africa.

Just before I left Nairobi for the states, my landlord informed me that he was going to put a new roof on my house while I was gone. So, I had to take all of my antennas down, and I haven't been on the air since, except for the local 2 meter repeater. I have a week off so I hope to get at least my G5RV back up. Unfortunately, the new roof is peaked and made of aluminum, where the old one was flat concrete.

I'm due out of here *[Kenya]* one year from now, and have just sent in my bidlist. On that list is Cairo (SU), Karachi (AP), Bonn (DL), and Miami (W4?). I took a trip to Bahrain (A92) early in September, and stopped off in Cairo for a few days to look the place over. I liked what I saw, so put it at the top of my list. Pakistan is also a good assignment, except that they refuse to issue ham licenses to foreigners. However, I have a good friend, Ben 5Z4BG, who has already received that assignment, and he will do what he can to remedy the situation. We'll see.

I was looking at the list of Hambassadors, and I have been in about half of those countries, but I've only met one of the Hambassadors personally. *[Me, too! Hopefully there will be more.—Arnie]* While I was stationed in Manila from 1981 to 1985, I used to visit Hong Kong quite regularly. In fact, it is still my favorite place in the whole world. In any case, I got my VS6 license with the help of Hambassador Phil Scott VS6CT, and operated from his QTH on a number of occasions. That was before he moved to the fancy new QTH that I saw pictured in a recent issue.

I'll pass along some info on what is happening out here as soon as I get back into the swing of things. 73.

SPAIN

Woodson Gannaway N5KVB/EA
Apartado 11
35450 Santa Maria de Guia
(Las Palmas de G.C.)
Islas Canarias, Espana

Even though I still have the same restrictive antenna situation, I'm looking for more contacts with my friends in the Americas, both North and South. And to spread the word maybe my editor will let me run a column or two in Spanish to see what we can stir up. *[What do you readers think?—Arnie]* Sometimes we forget how much we lose by assuming that everyone speaks English. True, English is the official language of all hams, is universally used in the sciences, and was recently selected as the official language for the European Common Market, but it is not our job to rub people's noses in it! If you want to be a friend to someone, you can pay them no greater compliment than to learn their language, and work, really work, to understand their culture. It is an adventure.

Christmas Day I visited the Soviet training ship *Sedov*, a beautiful 4-master. Right, a sailing ship. I've got a soft spot in my heart for them, and I've waited for over two years for the chance to visit one. This time it finally worked out, and I spent a pleasant hour and a half with her.

I spent a few minutes with the radio officer, Igor, who spoke passable English. He showed me the radio room and the inside of one of their Russian-made transmitters. It was extremely well laid out and well made. Big and heavy, he said. On a ship that is no problem, I replied. He was extremely pleasant and I'm sure he spoke other languages, and once again, I was humbled by the thought of our unspoken attitude of superiority in assuming that the world should speak English, and we ourselves shouldn't exert ourselves in the least to learn other languages. Here I am with only two languages, trying to decide which will be the third.

The *Sedov* carries a crew of 195, of which 123 are cadets, and has an overall length of 117.5 meters. In 1982 she achieved a world speed record of 18.5 knots for her class. She was launched in 1921 as the *Magdalene Vinnen* under the German flag. In 1946 she was acquired by the USSR. She carries 17 sails; I almost got to see her set sail to depart, but had to go teach a class instead.

This year or next, I will be retiring my N5KVB/EA call for an EA8??? call for the rest of the time I live here in Spain. The residency papers are finally coming through, and that will be the practical effect in this area. Now I'll have to find other ways to effectively discourage people from using me just as a means to get a QSL card from EA8-land. Where there is a will, there is a way. I do run Morse in Spanish, and I might try that on them. I've taken Wayne's advice and developed a remarkable ability to not give signal reports even when asked over and over again. I guess it is a form of selective hearing; because if you ask or want to tell me about your hopes and dreams, what is new in your area (I asked a Czech ham that and he didn't let up for fifteen straight minutes!), or what you're excited about, they just don't make QRM that can keep me from hearing you. Unfortunately I do get wiped out by a lid once in a while, like anybody else.

A friend is checking out the situation of the 500th commemorative voyage of Columbus in 1992 as it relates to ham radio. Hopefully she will come up with something for us. Other than that, a Happy New Year *[A little late but well-meaning.]* to all of you, with strong wishes that whatever happens, it leads us closer to the world peace and unity that we all need and pray for. 73 once again, Woodson.

Great Ideas From Our Readers

Field-Strength Meter/Carrier Alarm/Sidetone Monitor

A field-strength meter has many uses. Besides the normal functions of checking the field around an antenna and measuring the front-to-back ratio of a beam, it is also handy in the shack. A glance at the meter when you key your rig shows that the antenna is radiating power. It can also be used when adjusting the antenna tuner for maximum output at minimum SWR, or minimum plate current if you use an amplifier.

A few junk box parts added to a standard field-strength meter will produce a loud audible signal when your rig—or your neighbor's—is keyed. Thus, it can also serve as a sidetone monitor. Many hams have separate transmitters and receivers, and often operate each on a slightly different frequency, including split operation. Unless they have sidetone monitors, operation can be difficult. An audible monitor like the one described here is somewhat loud (a piece of tape over the alarm unit will help), but it will enable you to send accurate CW.

I originally designed and built this instrument because the ham downstairs—my son Kraig WB2PLW—operates 100 watts, and our outdoor antennas are mere feet apart. What I needed was a carrier-operated alarm to warn me to ground my antenna, to avoid high levels of RF being pumped into my transceivers, whenever he decided to go on the air.

Figure 1(a) shows the result. I had already built a field-strength meter, so I merely added the few parts necessary for the audible signal. If you're building this instrument from scratch, a simpler and cheaper version is shown in Figure 1(b).

In operation, the 2N3904 transistor is cut off in the absence of an RF signal, and no current is drawn from the 9-volt battery. When a strong RF carrier is present, it is rectified by the 1N34A diode which places a positive bias on the transistor base, turning it on. The piezoelectric alarm forming the collector load draws between 8 and 12 mA through the transistor, and emits a loud sound. There is no noticeable time delay in the circuit; it will follow even a very rapid keying. An SPST switch controls collector operating voltage, so you can turn the audible section off while operating, as desired.

Any small NPN transistor will work in this circuit, as will any RF diodes. The 1N914 in the emitter is there to assure that the transistor remains cut off unless a very strong carrier is detected. This is necessary in some cases, if you are relatively near the transmitter tower of a local radio broadcast station. The "antenna" for the device can be several feet of wire, the length depending upon the strength of the carrier of your own or any nearby ham transmitting antenna. I use about 8 feet of hookup wire as an antenna for the meter. My transmitter is a 20-watter, and my son's runs 100 watts. My dipole and his antenna array are about 30 feet from my operating position.

The piezo alarm element I used is available for $1 from Hosfelt Electronics, Inc., 2700 Sunset Blvd., Steubenville OH 43952 (Cat. No. LERT) and operates from 2 to 12 volts DC. Any similar device will work as well, and you may have one in your junk box. The transistor, diodes, RF choke (if used) and bypass capacitor are not critical, and are available from Radio Shack and most mail order dealers, if you don't already have them in your junk box.

J. Frank Brumbaugh KB4ZGC
Buffalo NY

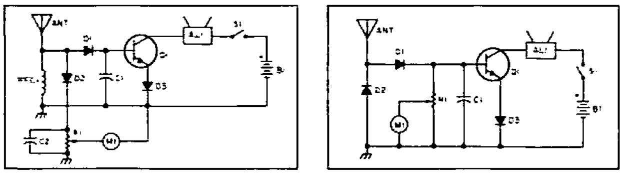

Figure 1. Schematics for the field-strength meter (a), and for the simpler version (b).

Parts List

C1, C2	0.01-0.25 µF disc, ceramic
D1, D2	1N34A, or equivalent
D3	1N914, 1N4148, or equivalent
M1	Surplus meter, 100 µA-1 mA
RFC1	1-2.5 mH
R1	5k or 10kΩ potentiometer
Q1	2N3904 (ECG123 equivalent)
AL1	Piezoelectric alarm unit
B1	9V battery

Covert Hamming

Continued from page 20

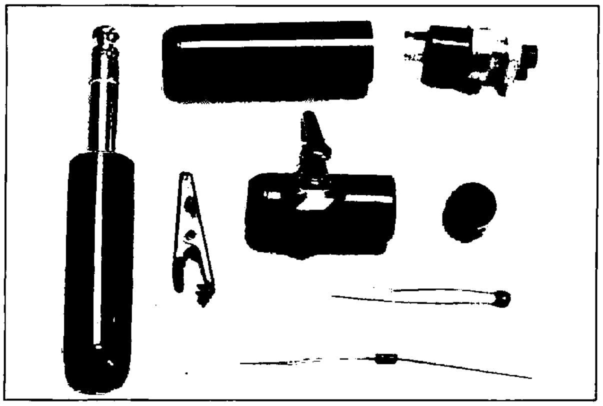

Photo C. Detail of the microphone and PTT assemblies. (Photo by Andy N6KAS.)

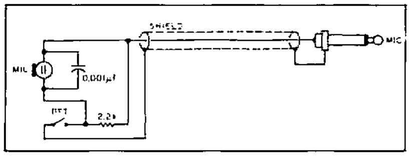

Figure 1. The original microphone wiring diagram.

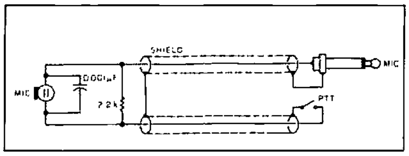

Figure 2. The modified covert wiring scheme.

three pins. Jumper the center pin to the pin which connects to the case, thereby creating a 2-pin element like the Radio Shack model.

After checkout, use a glob of silicon sealant where the wires enter the housings. This adds tensile strength.

You need some manual dexterity to solder the mike element. Be careful to avoid solder bridges and burned wires. Don't overheat the pins; there's an FET inside, and you could damage it!

Now that you've assembled your covert mike, just clip it onto your pocket or shirt collar and route the PTT switch down your sleeve or anywhere you can easily access it. Connect a small earphone to a mini-phono plug for receive and you're ready for some covert hamming (see Photos A and B).

The next time you're at a hamfest and you see someone talking to himself, it could be that he's been out in the sun too long . . . on the other hand, it could be that he's an Undercover Ham. 73

David Cassidy N1GPH

Are You Having Enough Radio Fun?

A few months ago, Wayne came to me and said: "How about publishing a tabloid-type magazine, just for the newcomers to amateur radio? We could fill it with simple construction projects and easy theory articles so people could actually start to understand what they have memorized to pass the tests. We'd review every kit we could get our hands on, and we'd review all the latest gear from a Novice/Tech point of view. We could publish articles about how to get started in packet, ATV, moonbounce, microwaves, DXing, RTTY, satellites and all the other fun areas of ham radio. We could even reprint some of the great stuff from the 30-year history of *73*."

Well, of course I thought this was a great idea. You don't have to be a rocket scientist to understand most of the stuff we put into *73*, but we still get lots of letters asking for easier construction projects. Even some folks who have been hams for 20 years or more could benefit from a publication that's totally geared to the newcomer.

"What should we call it?" I asked.

"Hmmmm...," Wayne paused. "How about *Radio Fun*? It's short, would look good at the top of a masthead, and it describes the whole concept in two simple words."

"OK. Sounds great! How many new staff people do you think we should hire?" I asked.

"None."

"None?"

"None...at least for now. Let's just do it with the staff we have and see how it goes."

"OK," I said, though a bit less enthusiastically than before. It would be hectic, especially when both magazines came to deadline at about the same time, but the people who put together *73* every month are some of the best in the publishing business. They could handle it.

"So...I guess you want a business plan, advertising rates, a production schedule and all the rest." I started making a few notes on a legal pad. "When should we launch this? How about next fall?"

Wayne didn't miss a beat. "How about in 90 days...just in time for Dayton?"

You have to understand something about Wayne Green. He is not fond of being told why something can't be done. He is less fond of people who find problems without finding solutions. He also has very little patience with people who want to write reports, schedule meetings, "do" lunch or partake in all the other time-wasting activities that are a substitute for actually working in your average American business. I was trapped, and I knew it.

"We'll get right on it."

A New Ham Publication

For the past three months, the entire staff has been hard at work, making Wayne's idea of a newcomers' magazine a reality. Ads have been sold, columnists have been lined up, articles have been picked and edited, and the end result will...as Wayne "predicted"...be introduced at Dayton.

Radio Fun is for every ham, especially Novices and Techs, who wants to have more fun with amateur radio. We want to encourage everyone to upgrade, try a new mode or build a circuit. We want to give you the confidence to build a simple QRP rig and then go up on top of a mountain and have a ball with it. We want you to get involved with your local club, throw out all the old farts, and start promoting amateur radio as the fun hobby that it is.

Radio Fun will have monthly columns explaining radio theory. This is the stuff that most of us simply memorized in order to pass the test. Don't panic! This will be easy. If you follow the monthly column, you'll start to understand basic electronics and radio. Then we'll take you through the General class material, so your upgrade will be a snap. We've got Gordon West WB6NOA to write the monthly upgrade column. If you've ever been to one of Gordon's upgrade classes, or if you've even listened to his CW training tapes, you know that this is going to be fun.

Radio Fun wants you to have fun with whatever license you have. That's why we've got people like Carole Perry WB2MGP and Michael Geier KB1UM to write columns on all kinds of fun things to do. Bill Brown WB8ELK is going to help you get started in some of the less active modes like ATV, UHF/VHF DXing and microwaves. We want you to have fun with amateur radio, and we're going to show you how to do it.

You want simple construction articles? We got 'em! By the bushelbarrel-full! QRP rigs, antennas, test gear, station accessories...you name it, we got it. We'll make sure even a beginner can understand how to do it, and we'll always make sure that you can get the parts.

How about kits? We'll be reviewing every kit we can. We'll actually build them and report to you on how the kit rates. Are the instructions clear? Are all the parts included? Does the project work as advertised? Was the company available to help with any questions? This is the stuff you need to know BEFORE you buy a kit...and we'll tell you.

All product reviews in *Radio Fun* will be from a newcomer's point of view. We're even going to go back and reprint some reviews from the last 30 years of *73*. Since so many newcomers buy their first rig at a flea market, we figured it would make sense to publish reviews of this older gear.

The special premier issue of *Radio Fun* should be at your local ham store in a few weeks. It's a big, tabloid-sized newspaper, so you can't miss it. We'll also be sending them to as many hamfests and flea markets as we can. If you're a recent Novice or Technician, you just might get a free copy in the mail.

If you want to guarantee your copy of the premier issue, you have to subscribe BEFORE it is released. We're only printing a limited number, and when they're sold out...that's it. Check out the subscription ad in this issue of *73*. The charter subscription rate is only $9.97 for 12 issues. To sweeten the deal, we're collecting savings coupons from several advertisers. Everyone who subscribes at this pre-publication rate will receive at least $25 worth of coupons for all kinds of great products, including "buck-off" coupons for Uncle Wayne's Bookshelf. So you really can't lose.

Everyone at *73* is very excited about this new project, and we've received support from the biggest and best companies in the amateur radio industry. Now, all we need are readers. I hope you'll be one of them. After all...couldn't we all use a little more fun? 73

A Mixed Bag

May is one of those months that lies between the excellent propagation of the spring equinox and the poorer HF DX of the summer solstice, and therefore exhibits both good and poor DX conditions. Usually, the better conditions exist closer to the first of the month, and the poorer conditions toward the end...but "usual" doesn't always mean this month and this year!

For example, just a few months ago, most propagation analysts were surprised by the "plateau" in sunspot numbers accompanied by a reduction of solar flux that lasted nearly six months. No one could safely predict what would happen...and Old Sol fooled us again, as just two weeks ago, he showed a solar flux well over 300, one of the highest in this cycle. Does this mean, then, that we may have a double peak, or what? No one knows. Theoretically, we should be starting on the down side of Cycle 22. And perhaps we are; but Old Sol may have a few surprises in store yet.

Specifically, for May, you can expect a possible few "Poor" (see the calendar) propagation days centered around the 7th or 8th, and again around the 16th. The last week or so is expected to be only "Fair" to "Poor." The "Good" days are anticipated between the 1st and the 5th, the 10th to 14th, and the 19th to the 22nd of May.

Keep your ears and receivers tuned to WWV for late predictions and recent changes in the flux levels so that you can take advantage of conditions as they occur. The 18-minute, after-the-hour broadcasts at 5, 10, or 15 MHz are the ones I use; most frequently, the one on 10 MHz. Remember that you want a LOW "A" index (below 10), and a high solar flux index (above 180). This is not to say that higher magnetic field indexes and lower solar flux numbers render the bands unusable; it just means that they won't be as good for DX propagation. See you next month! 73

LETTERS

From the Hamshack

Tim P. Yoho WA3D, Lock Haven PA I read several letters in the April issue concerning dissatisfaction with service from American manufacturers of radio products.

I wish to report a very positive experience with a U.S. company, namely Heath. I built the Heath SB-1000 linear amplifier and had a problem with the output. After much searching by myself and several other hams, I sent the unit back to the factory. The unit was returned several weeks later with a plate choke modification; it worked properly for a few days, then the original problem returned.

I wrote Heath about the problem, and the service manager immediately responded, requesting that I send back the unit. He indicated that Heath would reimburse me for the postage (which they promptly did), and give the unit priority treatment. Two weeks later, it came back with an RF choke and 3-500Z replacement at no charge. The unit has worked well since, and I am pleased with the attention and concern expressed by the service people at Heath.

James S. Waters W5YG, Houston TX Now that no-code is a reality, how about some "2 meter FM on a shoestring" like *73* had *years* ago? Let's show poor college students that they *can* afford this hobby.

It's already in the works!... Bill WB8ELK

Jim Kelly KK3K, Philadelphia PA I enjoyed the April editorial, as always. I chuckled at your comments about giving basically the same pep talk each year. I enjoy it nevertheless, because it is one of the few indications that there is life still left in the hobby! What a dull bunch we must seem to the uninitiated who stumble into Hara and cannot even get a response from the hoards glued to their HTs, stooped over tables full of connectors.

Ham radio's best kept secret is how much fun and how easy it is to work OSCAR. The sunspot cycle will soon start to decline, and I asked our club members, "What will you do then?" I pointed out that OSCAR-13 work is reliable, full duplex, not propagation-dependent, and requires small antennas. You can do satellite operation for the same amount of S or less than HF. It offers plenty of DX and rag-chewing, is relatively QRM and lid-free, and available to all hams with Technician class and above licenses. It's a great opportunity for fun in ham radio for our new codeless Technicians!

Doug Brock, Huron SD On March 2, I entered the Amateur Radio Service as a no-code Tech, and I'm proud of it. I had played with the idea of becoming a ham for about nine years, then about six months ago, I decided to get serious about it. I was studying for the Novice when the no-code class came up, so I grabbed a Tech book and went for it. I encourage anyone thinking about amateur radio to go ahead and go for it. But don't stop. Keep going up the ladder. I am.

As for guys like "N0" in the March issue, ignore him. There's always a few sour apples in the bunch. If you're tired of the garbage on 11 meters like I was, get out of there. The best of luck to anyone studying for that next test, for any class license.

Norris Carden, Shreveport LA I'm possibly the first of a group that some people fear will show up in mass and take over the precious ham bands. I'm a no-code Tech. I passed the written tests with just a little effort last February. To me, code was an unnecessary, and to some degree unreasonable, way of communicating.

I'm a professional broadcaster, and I've worked in radio as a DJ, newscaster, sports reporter, and program director. In TV, I've been a news photographer, reporter, director, and now a producer. My words, spoken by myself or by others on the air, are heard by thousands and sometimes millions of people. I must be responsible for and careful with my words. I plan to use on the ham bands the same communication ethics and practices I have used as a professional broadcaster.

Unless I and those around me who are interested in the new license are a fluke, most of the first wave of no-code Techs will be those who have always had a legitimate interest in the hobby, but who were put off by the code requirement. Many of us are already professionals in communications and electronics. The best way to guarantee no trash comes into the hobby is to not construct barriers at the entrance, but rather to guide those who come to the door. Give us a chance and teach us your ways.

Code does not a great radio operator make. Thanks to the FCC for giving me an opportunity to get into the hobby. I'll see you soon on 6 meters and above... hopefully in a year, I'll see you on HF as a General, then as an Advanced... but not with CW.

Say, if the code requirement were eliminated for all license classes, perhaps we could have a super-duper theory test (like 100 fill-in-the blank and essay questions—and no book with the answers in it, either!), and on-the-air evaluation of proper operating practices!... Linda KA1UKM

Jason Kelly NO0CALL yet, Fort Dodge IA It has finally happened! No code. I have been monitoring radio communications for over three years. From the beginning, my main interest has been VHF. I never did understand why a bunch of old men insisted that I learn the code when it is all but nonexistent in the bands above 30 MHz. I have passed the written portion of the Novice test, but have failed the code test three times! It drives me crazy. It is hard for me to waste time learning the code only to forget it after passing the test.

Many hams feel that the no-code Tech should not be allowed access to the 2 meter band. Why? They contend that the band is too crowded, and that there isn't room for "glorified CB operators."

Here in Iowa, I can monitor 20 repeaters all day without my scanner stopping more than three times! When it does, it's usually just some old man kerchunking to see if the unexercised repeater can still hear his handi-talkie that hasn't been charged in five years. Why should I become a ham? There are so few people willing to talk to some new kid under the age of 50. It has been many times that hams driving through the area check in on the local repeater only to be ignored because the old men don't know who they are.

Everything I have learned about amateur radio has been from *73* or Ron KF0LR. Ron deserves a medal of honor from hams trying to promote the hobby. He talks to anyone who might be interested in ham radio. If it weren't for KF0LR, ham radio would be dead in this community. Ron is why I would become a ham. He needs help promoting this great hobby. He cannot possibly elmer everybody that is interested!

Why doesn't the ARRL want new hams in the hobby to have access to the 2 meter band? They certainly aren't using it! If they don't, it will be taken away. Give it to the no-coders; we'll use it to promote ham radio and get more people to join the hobby and make it great again! I'm ready for my test. See you on the repeaters!

Frank Muratore KB2EZV, Copiague NY I would like to comment on an article, "Behold the Back Packet," in the December 1990 issue. Construction could have been simplified by using an electric knife to cut the foam. I have been using this technique for quite some time, and find that the foam cuts like butter.

Adam Harrod, Montpelier VT I am an SW listener, and have been for the past 10 years. As I am not a ham, I cannot transmit to receive any QSL cards. Is there any way to receive them?

Have cards made up for yourself with "SWL" printed on them instead of a callsign. Send your cards out to stations you hear, and you can send them a signal report. Request a QSL card in exchange.... Joyce Sawtelle

Stephen Barnett, San Carlos CA Your editorials remind me of a book published about a man in the village of La Mancha. His name was Don Quixote, and if I remember the story right, he liked to joust with windmills. Mr. Green, your windmill seems to be the ARRL. I keep reading your column with much interest. I am studying to become a Novice, and the more I can learn about what is happening in the hobby, the better I'll be able to operate on the air.

I have many questions. What good will the ARRL be to me when I get a license? How will the ARRL help me if I make an FCC error? Will the ARRL represent me in local, state, and federal government? How good are the ARRL publications? What about a magazine geared to the beginner in ham radio?

What can we do to advance, enhance, and expand amateur radio? Many people have lost life's challenge. You see school children "hanging out," young adults in cocktail bars, others sitting in front of the TV.

While SWLing on 10 meters, I heard a man in the San Jose area, who regularly sets up a ham station at the Children's Museum and lets the children become third-party operators. Listening to the hams talking to the children was quite interesting. This ham is doing a lot on his own time to further ham radio. The hams he contacted were also doing ham radio a good turn.

Enclosed is my subscription. I look forward to my first issue of your magazine so I can keep up with the man and his windmill. The local ham store is sometimes sold out of *73*, and now I will not miss out. Your ideas are up front and needed, the wheel that squeaks gets the grease.

The magazine you're looking for is being started—Radio Fun. The premier issue will be out in time for Dayton. It'll have simple theory, simple construction projects, kit reviews, easy explanations on how to get started. Subscriptions are $10/year.

Now, the ARRL. I can't think of any good the ARRL will do you other than let you read QST. *The ARRL won't help you with the FCC. They represent their own interests, not necessarily yours.* QST *is worth getting as a reference, but it's not for newcomers.*

Amateur radio can help kids enter a whole new world—technology. It can offer them fun, a whole array of exciting careers, and a way to cope with the teen years. But we need to make this world available to the kids through school radio clubs.... Wayne

Ocran M. Carr K9RGV, Racine WI I am a long-time subscriber to *73*. In one of your editorials, you asked the readers what they suggest you do to get their friends to subscribe to *73*.

I suggest you devote one page each month to some deserving black amateur radio operator. As publicist for the Omik Amateur Electronic Communications Association, I can tell you that 10% of today's hams are black, and we have never received the recognition that we deserve. Some examples: Mr. Everett Refroe W9HG, electronics instructor during WWI; Mr. James Cheeks W6TXW, an aviator who trained pilots for the Ethiopian Air Force, and introduced amateur radio to that nation in 1943; Mr. Robert F. Scott W2PWG, technical editor for *Radio Electronics Magazine* for 30 years; Mr. Jack Chancellor W9SON, a physicist at Fernion Lab. And the many black doctors who are hams even surprises me.

I can supply you with photos and information each month that will prove to be interesting and informative. I can guarantee you that our members will subscribe to *73* if they think there is something in it about our organization, and white hams will buy the magazine because they didn't know there were any black hams, and to see what they are up to, hi.

Yep, I'd be interested in some articles on black hams who've contributed to the hobby. But I suspect your estimate of there being 50,000 black hams is wildly optimistic.

While it appears to me that blacks are much more disintegrated than they were a few years ago, and generally tend to go to much greater lengths now to avoid contact with whites, that doesn't explain the almost total vacuum at Dayton and at every other hamfest I've attended in the last 50 years.

Ocran, I've met far more gay hams than black! And the same situation held when I was involved deeply in computers—almost no blacks. I meet many in the music business, but mostly as performers, not as businessmen. This has nothing to do with prejudice or bias; this has been my experience. It's the same for women—few in either radio or computers. Now how can this be explained? What's your take?

... Wayne

NEVER SAY DIE

Wayne Green W2NSD/1

Technology Fugits

On the off chance that your finger on the mike button may be tired for a moment, let's leave your total devotion to the survival at any cost of our hobby of antique technologies and take a short trip into the present.

Are you prepared to get up in front of your local ham club and explain exactly how DSP works? That's Digital Signal Processing, old chap. It's one of those newfangled Japanese developments with which they're whipsawing what shreds we have left of our old consumer electronics industry.

Yamaha came out with the first practical DSP unit two years ago, followed a year later by Sony. I think I wrote about the Yamaha system at the time, in case your memory is still intact. It's a clever invention and will, I expect, get very popular for home entertainment systems. No, it doesn't have a lot of application in amateur radio. But some other new developments have! I'll get to those.

As an electronics "expert," a little facade we practice on our friends and family, we really should have at least a vague understanding of modern technology.

Okay, DSP. What they do here is to shoot off a gun in a series of different types of concert halls and rooms. They record the resulting echoes. Then they set about digitally copying the echoes and phasing which makes each hall sound different. The computer replication of each hall is then programmed into chips. Thus, you can play a CD and make it sound exactly as if it is being performed in a small supper club, in Carnegie Hall, Westminster Abbey, Avery Fisher Hall, etc.

The only hitch in the wagon here is that the original CD sound should be recorded in an anechoic room instead of a normal recording studio. Anechoic means without any reverberations at all. A totally silent room. These are not easy to build and are a real corker to use. They're generally used for loudspeaker development and other scientific applications.

Adding DSP to normal recordings may enhance their sound to some ears, but the result won't be a Boston Symphony Hall sound. Alas, as far as I know there aren't any anechoic recording studios yet. Well, there will be soon since we're building one. To make it possible for the performers to hear what they're playing we're feeding the sound back to them, complete with DSP ambiance. Far's I know we'll have the first DSP-ready CDs on the market in a couple months.

We're in the throes of finishing this new recording studio in time for Scott Kirby to lay down tracks for a third Scott Joplin ragtime CD.

How'd all that happen? Well, I've had it in my mind (no comments) ever since digital audio got started that there would be a growing need for digitally ready state-of-the-art recording studios. I decided to try and not be five years ahead of my time on this, so I've been hanging back.

Kirby did his first recording in the Peterborough Unitarian Church. The sound was pretty good, but the Steinway Grand was crummy and the recording sessions had to be done in the wee hours to avoid the noise of trucks driving down Main Street. That was a downer.

The second CD was recorded in the garage at my farm in Hancock using a couple of 1890s upright grand pianos that Knud Keller KV4GG (now KC1QP) found for us. We jury-rigged some wooden panels to give the garage a nice bright sound. Indeed the CD got a 10/10 rating...as high as it gets. It's been selling like hot cakes too.

A few months ago one of my magazine circulation people, Phil Martus, wanted some spare time work so I set him to straightening out my barn. He did such a good job he ended up with the whole center section empty. Hey, what a great spot for a studio! By luck Phil had lots of building experience, so he volunteered to take on the construction job.

Our recording engineer, Dave Torrey, designed the studios and Phil, with some help from friends, did the construction...all in a few weeks. A studio is enormously complicated. The walls have to be double and isolated from each other. Even the control room has to be isolated, with double windows. Bass-traps have to be built into the ceiling and walls. The heating, air conditioning and humidity control systems have to be totally silent.

One studio is normal and a second has sound absorbent walls, ceiling and floor, so it'll be the first recording studio in the country capable of turning out digital signal processing (DSP) ready recordings.

DCC

That stands for Digital Compact Cassette. Philips (Holland) and Tandy (Ft. Worth) are working on a new approach to digital tape. DAT, digital audio tape, requires a new format which is just like a miniature video cassette. DCC uses a cassette which is the same shape as our regular audio cassettes. With a DCC system we'll be able to play both DCC and audio cassettes with the same player.

Which brings up the question of how, without a high speed rotating recording head, can they get all that digital information on that eentsy tape? Well, what they've done is to find ways to cut down on the amount of information required to make our ears think they are hearing digital quality sound. Even though they've cut the amount of information down to about 25% of what's recorded on a DAT system, it still sounds good. I've listened to it.

If we have any technically inclined hams left they might be encouraged to see what they can do about digitizing the really low quality sound we require to talk all day saying nothing (with a few exceptions). Then they can start to work with every data compacting system they can find to improve the throughput.

Hmmm, you know, if we were to first send out an algorithm which makes it possible for a receiver to imitate our individual voice, then all we'd have to do is get the words we're speaking through as compactly as possible and reconstruct our voices with the algorithm. Follow me? Well, it was just a thought.

Every time I get together with engineers I'm amazed at how much progress is being made in data compacting. There are some new systems that were being discussed at the Consumer Electronic Show in Las Vegas in January that are able to cut the data by 1:77 and still not lose anything! They're using some of these approaches to get the bandwidth of HDTV down.

Of course I joke about our being able to get the bandwidth of ham transmissions down to under 1 Hz. Sort of joke, that is. If you've listened in to much ham gabble you know that the amount of data throughput is minimal. Call, name, town, signal report and...? Once those have been said a few times many ops seem to run dry. My suggestion is that we send our call and then a dot which will tell the other op that our name and town are in the *Callbook*, so look it up. The report is 5-9 (what else is there?). Please QSL. 73. Two dots coming back says roger on your name and town in the *Callbook*; roger on the 5-9, you're the same; roger on the QSL; 73. Save a lot of time and hassle.

If you find good information resources for amateur radio associated new technologies, whether magazines, books or newsletters, let me know so I can pass the word along. And if you come up with some ham applications, please consider *73* as a place to get published.

Okay, Experimenters!

There are some new chips which should have you busy breadboarding in short order. They are somewhat expensive, right out of the chute, but I expect we'll see prices declining as production ramps up. Now stop fussing, I'll tell you what it's all about. They're called analog storage chips.

If you have to ask me what to do with an analog storage chip, I know you're asleep at the switch. The whole idea should have had you jumping out of your chair with excitement.

What can you do with 'em? Well, how about building a semi-intelligent QSO machine? Each chip will hold up to 20 seconds of voice, so you're going to need a few. Let's say you rig up the first one so that when you make a contact you speak the other chap's call into a chip. You might store his name in a second chip. Are you getting it yet?

When it's your turn to transmit you turn on your rig and the first chip gives his call. Your QSO machine automatically switches to a series of chips which give your call, your name, signal report (5-9, of course!), and all the stuff you always say during your first transmission. The chip with his name recorded on it clicks in whenever your QSO chip flags it. This personalizes the contact.

A perfectionist might use a separate chip to store the signal reports and just push a button to indicate which report will be given.

All it'll take are three or four chips to hold your normal QSO information, the stuff you've been repeating over and over for years with little variation. You can even free yourself of having to record the other chap's name 90% of the time by having a dedicated name chip with 20 seconds worth of names on it. You just push the button for the name and it'll switch it in for you.

How does all this work? It's simple, the chip samples the voice message 6,400 times per second, digitizing it. This gives you a 2.7 kHz passband, which is fine for most hamming. They have a 3.4 kHz passband chip if you don't mind spending a little more per chip and only getting 16 seconds of voice. Being thrifty (cheap), I know you'll go for the 2.7. Hi-fi fanatics may

STS-37 Success!

Some exciting amateur radio firsts were achieved during the lastest flight of the space shuttle *Atlantis*. Astronaut Ken Cameron KB5AWP reported seeing good video from KC6A in Los Angeles, WA4NZD at the Marshall Space Flight Center, N9AB in the Chicago area (the farthest north contact), and WA3NAN at the Goddard Space Flight Center (linking via the 40-foot dish at the U.S. Naval Academy, shown in the May "QRX"). In addition, Andy N9AB sent up a video tape of the STS-37 launch. This is the first time live television has been uplinked to any U.S. spacecraft, and the first time a shuttle crew could watch their own launch while still in space.

It is uncertain at this writing whether the other two uplink sites were successful. KE4PT at the Motorola club in Florida, and the Johnson Space Center radio club (W5RRR), made several attempts, which may be on the second video tape recorded on board the orbiter.

In another first, a brief contact was completed between Ken Cameron KB5AWP on board the *Atlantis* and Musa Manarov U2MIR on the Soviet space station *Mir*. Musa later confirmed the contact via a message on his orbiting packet BBS. On the tape recorded on the shuttle, Musa could be heard clearly.

A number of school contacts were established via a telephone bridge during several of the passes. Each of the all-ham crew answered questions from members of the selected schools.

A problem occurred in the audio path of the SAREX module which prevented any packet contacts or SSTV uplinking. However, at least a few SSTV downlinks were successful.

Watch for the complete STS-37 story in the July issue of *73*. *Thanks to Lou McFadin W5DID, Andy Bachler N9AB and Dick Christiansen KK4HF for the above info.*

Amateur Radio Talk Show on Satellite TV

"QSO Amateur Radio," a weekly TV show hosted by Jack Smith WA2QYT, has been active over the past few months to an ever increasing audience. The video portion of the show airs every Monday night from 10 p.m. to midnight on Spacenet One, transponder 15 (S1-15). Plans are for a call-in talk show from 9 p.m. till midnight, Mondays through Fridays, on the same channel. The nightly talk shows will cover topics on amateur radio, specialty modes, shortwave listening, and satellite TV.

You don't need a satellite dish to tune in to the program. All amateur radio operators have permission from QSO Amateur Radio to retransmit the show over both audio and ATV repeaters. Also, every Tuesday night from 9 to 10 p.m., the ATV net on 3.871 MHz will actually be uplinked to the satellite. Check into the net and hear your signal via the satellite as well! Bill WB8ELK will host an ATV talk show after the net until 11 p.m.

The talk shows can be heard on the standard 6.8 MHz subcarrier, except Mondays between 10 p.m. and midnight when the talk show will operate on the 6.2 MHz subcarrier (concurrent with the video show).

For more information, contact Jim Bass at (315) 673-3752.

Photo B. Moody T. Law WO6I, the 22nd president of OMIK, will serve the 39-year-old organization for the next two years.

Videos Needed

Tapes of the recent SAREX hams-in-space mission are needed to produce a new educational video. Specifically sought is footage of youngsters in schools making contact with the all-ham crew on the shuttle. It may be in Betacam, 3/4" U-Matic, M-II or 1" Type C. Also acceptable are tapes on the Super VHS (S-VHS) and Hi-8 home video formats. NOT wanted are standard 8, VHS or VHS-HQ, Betamax, or home movie film. Producers Roy Neal K6DUE and Bill Pasternak WA6ITF will use as many shots as possible in the finished video, due out in late summer or early fall. Include a self-addressed, stamped mailer, if you want your video back. Send all videotapes to SAREX '91 VIDEO, %Bill Pasternak WA6ITF, 28197 Robin Ave., Saugus CA 91350. *TNX Westradio.*

Power Audit Results

As a result of "power audits" of 209 amateur radio stations last winter, the FCC has come to three conclusions. First, that most amateurs are not operating at minimum power as required by Rule 97.313(a). Second, that reduced power can alleviate significant reception interference problems in consumer electronics gear without serious degradation to communication capabilities. And third, that in addition to lowering output power, installing filters at either the transmitter or receiver might be required to eliminate interference.

FCC Field Operations Bureau Chief Richard Smith said that 75% of the stations surveyed experienced no degradation when their output power was reduced by more than 50 percent. However, even running low power cannot solve interference problems in many cases.

The study is being forwarded to

the Private Radio Bureau for evaluation. It would be the purview of the PRB to make any recommendation to the Commissioners for regulatory action. *TNX* Westlink Report.

OMIK's WQ6I

The nation's largest black amateur radio organization, OMIK Electronic Communication Association, elected a new slate of officials this year at a convention held in Atlanta, Georgia. Elected for president was Mr. Moody T. Law WQ6I of Claremont, California, to head OMIK for the next two years. Mr. Law, the twenty-second president of OMIK, majored in biology at the Spring Hill College in Mobile and also in Nashville at the Tennessee A&I University. He completed graduate work in business administration at Laverne University in Laverne, California. For the past 19 years he has worked with Schering Labs, training and supervising pharmaceutical service representatives. He is past president of the Los Angeles Amateur Radio Club and is committed to the challenges encountered by OMIK.

The name "OMIK" originated from the first letters of the states of Ohio, Michigan, Indiana, and Kentucky, where the first members of the organization lived. OMIK had its beginnings on the campus of Wilberforce State College in Wilberforce, Ohio, in the early '50s. The original group of 11 black members has grown to several thousand, with members located in 42 states and several other countries. A sizable number of YLs and XYLs have been associated with the group since its inception, and they have been invaluable to its success over the years.

OMIK's fundamental purpose is to promote fellowship among those interested in the advancement of amateur radio. This includes electronics, technology, public service, and the promotion of international good will. OMIK also serves as the national organization for a network of local amateur radio clubs. Any licensed amateur radio operator who supports the ideals of the association may join OMIK.

OMIK membership enjoys a diverse range of professional, skilled, and retired people—all brought together by their common interest in and enjoyment of amateur radio. *TNX Ocran Martin Carr K9RGV.*

Luke Ward KC4UJS

Every Friday evening at the Springfield Estates Elementary School in Springfield, Virginia, eight-year-old General Class Luke Ward KC4UJS and his father, Keith Ward KC4TZJ, teach amateur radio to a group of 17 students and 15 parents. Studying together makes learning fun and easy for everyone. Parents and children are members of the Springhill Estates Ham Club, the second ham club started this year by volunteers of the Mt. Vernon ARC. Luke Ward KC4UJS is in the front center row in the photo, wearing his blue Mt. Vernon ARC shirt.

KC4UJS sometimes writes for "The Bacon Bits," a newsletter for young hams and hams-to-be in kindergarten through eighth grade. It is published by the Marlborough Communications Club and the Marlborough Desktop Publishing Class in Kansas City, Missouri. *TNX David Cowhig WA1LBP.*

Ham Arrested

Last April, amateur radio operator James A. Haas of Athens, Ohio, was arrested by federal authorities for making false distress calls. At a hearing, he was released on $100,000 personal recognizance bond. If convicted, Haas could get five years in prison and be fined $250,000.

Haas is suspected of making dozens of fake distress calls in Athens, Cincinnati, and Columbus, Ohio, and also in Kenton County, Kentucky. Many of the calls resulted in massive searches by police agencies. One call resulted in a 10-hour search involving 15 police agencies and helicopters.

FBI spokesman Ed Bolt said the calls also included tones and noise broadcast over police frequencies, interfering with legitimate police transmissions, and some "harassing and obscene statements" over the Kentucky State Police frequency.

Haas was located by the FCC, FBI, and Prince William (Virginia) police using sophisticated radio direction finding equipment. A cassette marked "siren" with a variety of sounds of police sirens, was found in the van with Haas. Haas was in the Washington, D.C. area to attend an amateur radio convention.

The 39-year-old ham is adviser to the ham radio club at the high school where he teaches physical education. *TNX David B. Emmons for the* Washington Post *clipping and* Westradio *for the AP material.*

Three Bands with One Rock

Versatile QRP transmitter for 80, 40 and 20m.

by Mike Gasperi WW9X

When building simple QRP rigs, the most expensive and difficult part to find is the crystal, or rock. Usually they have to be specially ordered, and delivery may be slow. The transmitter design in this article allows the same crystal to serve multiple bands, which makes for flexible and economic operation.

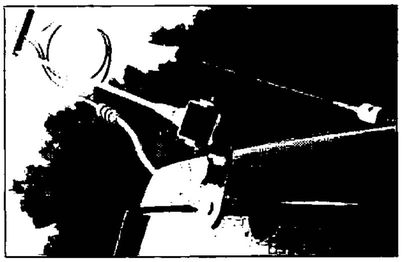

Photo. A peek inside at the finished circuit.

The Circuit

The circuit consists of seven basic elements: the oscillator, divider, keying circuit, amplifier, receiver limiter, filters, and power supply. It's designed to operate from 12 VDC, with about 1 watt output on all three bands. Operation is simple. The desired frequency is selected for amplification, and the appropriate low pass output filter switched in line with the antenna. Forty meter band crystals can also be used in the oscillator, with division by two to get frequencies in the 80 meter band. Or you can use 80 meter band crystals with no division.

The transmitter block diagram is shown in Figure 1. Central to its operation is the fact that the amateur bands are harmonically related. Twenty meters is twice the frequency of 40 meters, and twice again that of 80. Normally, frequencies are synthesized upward, starting with a low one and doubling or tripling it to the desired higher frequency. However, digital logic chips easily divide high frequencies to low, and this is how I used one 20 meter band crystal to operate on 40 and 80 meters as well.

The Oscillator

The variable crystal oscillator is made from two TTL inverters in U1. Gates from the high power CMOS (HC) family should be used since they have much better logic levels and thresholds (nearly zero to Vcc) than other TTL families, such as LS. Vcc. Resistors R1 and R2 bias the gates into linear operation while variable capacitor C1 is used to shift the crystal frequency. The other inverters are used to buffer the oscillator and shape up the waveform.

Crystal X1 is a plated, AT-cut fundamental crystal in a HC-6/U holder. However, this oscillator design is very tolerant, and works with most microprocessor, color burst, and other surplus crystals. For three-band operation, the crystal must be cut for the 20 meter band. I use 14.060 MHz since it is the standard QRP for 20 meters. Divided by two, it gives 7.030 MHz, which is near the 7.040 MHz, 40 meter QRP frequency. Dividing by four gives 3.515 MHz for 80 meters, which is fine if you have an Extra class license.

You could also cut the crystal for the 14.11 to 14.15 MHz subband; this would make the divided frequencies near 7.060 and 3.530 MHz usable with a General class license. Unfortunately, not a lot of CW goes on that far up the 20m band, since other countries can broadcast single sideband there.

The Divider

U2 is a 4-bit binary divider that creates frequencies harmonically lower than the oscillator. Usually, only division by two or four are of any use for amateur operation, but connection to eight is provided just in case. The HC logic family should be used for U2 for reasons already mentioned. A 74HC163 can be substituted for the 74HC161 since the clear function is not utilized. All unused inputs to the chip must be tied appropriately high or low for reliable operation.

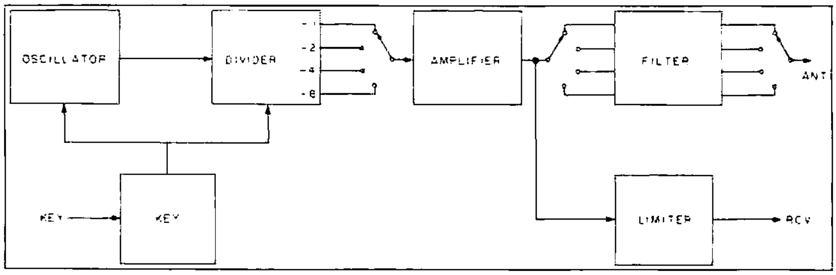

Figure 1. Circuit block diagram.

Keying

Keying is accomplished by powering U1 and U2 through transistor Q1. Voltage regulator U3 is used to create the five-volt power needed for the TTL gates. Wave-shaping is controlled by C5, C6, and R3. The values given create a crisp wave shape without noticeable clicks or chirps. If a keyer is used, it should be set for positive keying.

Amplifier

The selected frequency is first amplified in current by the emitter follower Q2. It then passes to the Class C output amplifier transistor Q3 via C8. Resistor R6 guarantees that Q3 is off during key-up, while diode D1 keeps the base voltage from going too negative. Transistor Q3 is a 2N2219A, which is just able to handle the 1 watt output power. It is inexpensive and easy to find. You should definitely heat-sink it.

Harmonic Filters

Depending on the selected frequency, an appropriate filter must be used to reduce harmonic content. Basically, the waveforms are square up to this point, and rich with odd harmonics. The three filters given are pi-configuration low pass, with 14, 7, and 3.5 MHz cutoffs. An option of bypassing the filters is given with S2 and S3, so that off-board filters can be used or circuits debugged. Changing frequency bands requires setting both switches, S2 and S3, so that only the desired filter is connected.

Limiter

Full break-in QSK operation is achieved by picking off the antenna signal with C11. During transmit, the RF is limited by a pair of diodes, D2 and D3. Although this only limits the signal to about 1 Vpp, it's sufficient to prevent damage to receivers. There is quite a bit of signal loss with this technique. An external transmit-receive TR switch is another good alternative.

Power Supply

Capacitors C4 and C9 filter the input voltage to the transmitter. The 5-volt power for U1 and U2 is created by U3, a TO-5 package voltage regulator. C2 and C3 are bypass capacitors located at each digital integrated circuit. Radio frequency choke L1 and

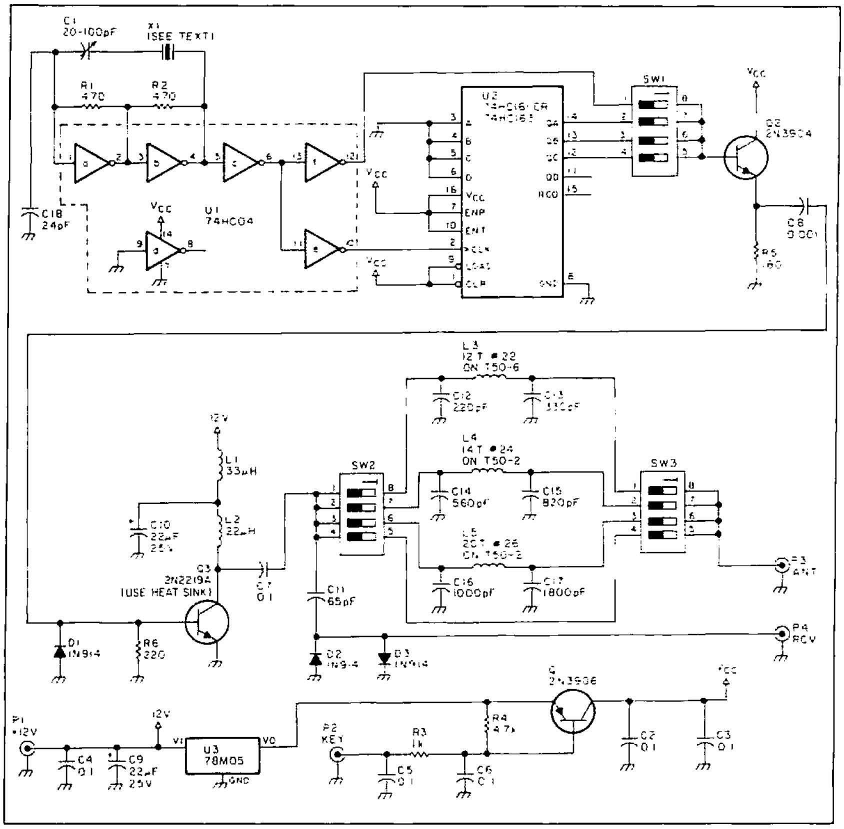

Figure 2. Schematic diagram.

capacitor C10 keep the 12 volt power to the final transistor clean and solid.

Construction Notes

A circuit board etching pattern is illustrated in Figure 3, and a component layout for the pattern is shown in Figure 4. Other construction techniques should also work. The digital integrated circuits need solid grounds and proper bypass capacitors. Toroidal inductors L3, L4, and L5 should be wound spreading the turns over about two-thirds of the circumference. Leads should be kept as short as possible on all components. The DIP switches need to be easily accessible when you're switching bands, so don't bury them in a deep enclosure. Variable capacitor C1 also needs to be available to fine-tune the operating frequency. Simple RCA jacks can serve for all four external connections; just make sure they are properly labeled to prevent accidental damage.

Performance

The prototype transmitter output power to a 50 ohm load with 12 volts input power was 0.8 watts on 20 meters, and 1.2 watts for 40 and 80 meters. Power supply input current was measured at 250 mA for an input power of 3.0 watts. This gives about 40% total efficiency for the entire transmitter. Harmonics were 30 dB down, and no key click or chirp was observed. Operation on as little as 6 volts

Parts List

C1	20–100 pF, mica trimmer
C2–7	0.1 μF, monolithic
C8	0.001 μF, disk ceramic
C9,10	22 μF 25V, electrolytic or tantalum
C11	65 pF, disk ceramic
C12	220 pF, silver-mica or polystyrene
C13	330 pF, silver-mica or polystyrene
C14	560 pF, silver-mica or polystyrene
C15	820 pF, silver-mica or polystyrene
C16	1000 pF, silver-mica or polystyrene
C17	1800 pF, silver-mica or polystyrene
C18	24 pF, disk ceramic
R1,2	470 ohms, 1/4 watt
R3	1k, 1/4 watt
R4	4.7k, 1/4 watt
R5	180 ohms, 1/4 watt
R6	220 ohms, 1/4 watt
D1–3	1N914
S1–3	DIP switches, 4-position
Q1	2N3906
Q2	2N3904
Q3	2N2219A, with heat sink
L1	33 μH, RFC
L2	22 μH, RFC
L3	12 turns #22 enamel, on T50-6
L4	14 turns #24, on T50-2
L5	20 turns #26, on T50-2
U1	74HC04
U2	74HC161, or 74HC163
U3	78M05 5V regulator, TO-5 package
X1	fundamental mode, with socket (See text.)
P1–4	RCA jacks

Suitable enclosure with mounting hardware.
A blank PC board is available for $4.50 & $1.50 postage/handling per order from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

73 Review

by Bill Brown WB8ELK

Get-Tech
George Tarnovsky KE2AM
201 RD2 Riley Rd.
New Windsor NY 12550
(914) 564–5347
Price Class: $69, $85 with battery-backed socket

The KE2AM Voice ID and Repeater Controller

Control your repeater economically!

How would you like a repeater controller/ ID that actually identifies in your own voice? George Tarnovsky KE2AM of Get-Tech has designed just such an animal. His controller provides you with the basic timing signals to put together a very economical repeater system. It even provides you with the capability of identifying in your own voice with the onboard digital voice recorder.

The Voice Recorder/IDer

The KE2AM controller is offered completely assembled for the amazingly low price of $69. All parts are mounted on a high quality 3.75" x 3.375" circuit board.

The voice record section consists mainly of a surface-mounted control chip, along with a 256K memory IC. A jumper chooses between 6 or 12 seconds of recorded message.

The unit is designed to take low-level audio from a microphone. I just hooked up my remote HT mike to the audio input terminals. To record your message, just flip the record/playback switch and press the momentary contact start button. When using other audio sources, you may want go through a potentiometer to drop the audio down to acceptable levels. The audio will sound clipped if you overdrive the recorder.

Now, just flip back to play, then hit the start button for an instant replay. You can choose two sampling rates via a jumper wire. In the 5 kHz rate, you get 12 seconds of message time, but you will notice some sampling distortion. For higher fidelity, use the 11 kHz rate, but you only get 6 seconds for your message. Even at the higher sampling rate, you'll notice something of a background hiss. Another jumper allows you to select a low-pass filter which eliminates most of this. Although low-level audio is all that is necessary for your repeater transmitter, the controller has an LM-386 audio amplifier which can drive a small speaker loud enough to hear in even the noisiest environments.

With the filter in place and at the higher sampling rate, I found the reproduction to be of excellent quality. Six seconds may not seem like a lot but it is more than sufficient for a repeater ID.

Repeater Controller

This board is not only a high quality voice recorder, it also supplies all of the timing signals necessary for repeater control. A connection to your receiver's squelch line is all that's needed to activate the transmit controller and timer logic. Your receiver's squelch circuit must be able to supply 3 to 12 volts when activated. In most rigs, it's possible to tap this off of the receive LED. When an open squelch signal is detected, the controller turns on an open collector transistor to key your repeater's transmitter. The transmitter enable signal is also controlled by the status of onboard timers.

Three separate timers, along with associated logic circuitry, comprise the controller section.

The **ID timer** makes sure that your repeater is identified every 7.5 minutes. It won't ID with each transmission. It will reset when first activated and identify with the next transmission after 7.5 minutes has elapsed.

The **time-out timer** keeps conversations from getting too long-winded. After two minutes of continuous transmission, it will drop out the transmitter until reset by the squelch line.

The **squelch tail timer** gives you 2.5 seconds of hang time when the repeater is dropped.

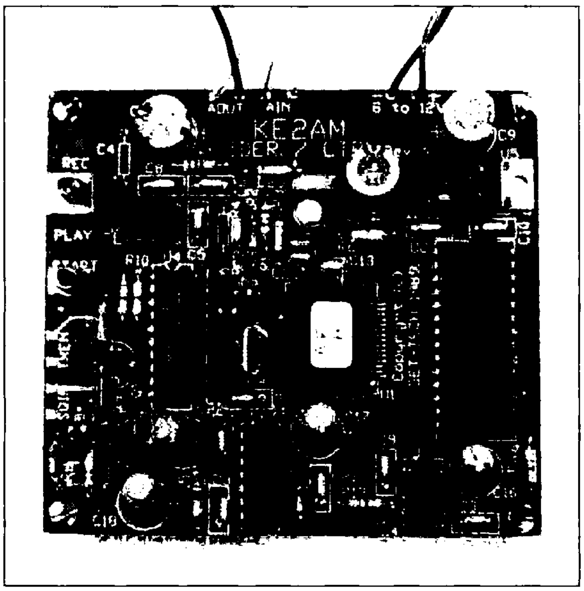
Impressions

I found the KE2AM controller to be a very convenient way to put together a basic repeater quickly and inexpensively. Using two HTs and this controller, I was able to put together a portable crossband repeater with relatively little fuss and bother. It's been great taking this to hamfests or up to mountaintops.

The controller requires 8–15 volts at 118 mA. The current drain may be a little on the high side, but most of it is due to the PAL logic array. The plus side is that the PAL circuit reduces the IC count considerably.

Since the RAM memory is erased when the power drops out, your voice message disappears. This could prove to be a major problem if your repeater site has a power glitch or outage. Fortunately, Get-Tech offers a battery-backed socket option that retains RAM memory when power to the controller is removed.

I highly recommend the KE2AM controller. It's a high quality unit that will leave enough money in your pocket to build the rest of your repeater.



The KE2AM voice recorder and repeater controller.

Tune in on Philately

Immortalized in stamps.

by Raymond Schuessler

All around the world, countries have honored amateur radio and ham radio operators on their postage stamps. Collecting these stamps can be a fun hobby for hams.

Postage stamps originated in England in 1840. From the beginning, postal authorities designed stamps to honor the great milestones in science, medicine, the arts, and history. The people and events so depicted have earned a permanent niche in world history—for stamps never perish. If archaeologists of the far future unearthed our civilization, they would have a good idea of our culture and history from our stamps.

Ham operators deserve the honor they have received in philately. When you hear stories of lives saved, you know these badges of honor are well-deserved. Stories I have heard include a New Orleans operator who heard an emergency call for snake serum in Columbia, and relayed the call; an operator who heard a call for help from a ship in the arctic that had struck an iceberg; and an operator in Canada who helped rescue four soldiers in Manitoba, 1,500 miles away.

The postage stamps honoring amateur radio commemorate the handful of pioneers in 1901 who, inspired by Marconi, the father of wireless communications, grew into an international fraternity.

In those days, all transmitting and receiving apparatus had to be assembled by hand, and there were few books and no magazines on the subject. Because of hams, many new inventions came into existence. For example, hams were the first to discover the value of shortwaves, which opened the way for TV and FM broadcasting. And it was a ham who helped track the first satellite.

The wartime stamps are well-taken, since World War II saw over 25,000 hams in uniform designing "commo" equipment, setting up global networks, and manning radar installations.

Israel honored its amateur radio operators in 1987. The Palestine Radio Club was organized during the British Mandate, and eventually became the Radio Amateur Association of Israel. These hams played an important role in laying the foundations of the Army Signal Corps, as well as the civilian communication network during the early years of the state of Israel. The association has 900 members, 700 of which hold official licenses.

Ascension Island issued a stamp in 1982 showing King George V making his first Christmas BBC radio broadcast to the empire.

A variety of old ham equipment is portrayed on some stamps. This adds to their collectibility. Even Disney's Chip and Dale get into the act on the Bhutan stamp shown.

Your Own Collection

If you want to start your own stamp collection, consult a stamp catalog (such as Scott's, Gibbons, or Minkusi in your local library. It lists or illustrates all stamps and their official call number and current value. The catalog is revised annually to include all new stamps and price changes.

Subscribe to a good weekly stamp newspaper (such as *Linn's*), which you can also look over at most libraries. Search their ads for dealers who specialize in the nations whose stamps you need. You can mail-order stamps, too.

You can also subscribe to a "new issue" postal service. The service will send you all the new ham issues as soon as they are released.

Visit a local stamp shop. They may have a good selection. You may be able to fill out some blank spaces in your collection. Used stamps are cheaper than new, mint stamps.

Stamps should be stored in three-ring plastic sheets with windows to protect the stamps from creasing, humidity, and dust. These sheets can be kept in a loose-leaf notebook.

Accidental Benefits

The greatest monetary profits lie in printing errors. Once a man in London bought a sheet of 100 nine-cent stamps. When he got home, he found that no price had been printed on them. A stamp shop bought the sheet for $60,000.

Another example: In 1918, the U.S. airmail stamp of the Jenny plane was printed upside down. Today, one of those stamps sold at a recent auction for $148,000!

Some ham club bulletins carry columns dealing with philately, and others carry stamp news over the airways, as they do in Canada, Sweden, Cuba, Czechoslovakia, Berlin, East Germany, Bulgaria, Belgian, and Portugal.

As a ham, you'll have a special advantage. You'll be able to ask ham philatelists to send you ham stamps from their countries. You'd even be able to trade your duplicates worldwide.

Few hobbies are more rewarding and useful than ham radio, with its friends, fun, and excitement. An interest on the side in philately will add to the fun. Tune in and see.

You may reach Raymond Schuessler at P.O. Drawer 69, Lake Helen FL 32744-0069.

Stamps from all over the world, honoring amateur radio and hams.

A Pseudo CW Filter

Be good to your ears.

by Jim Melton WR5B

To my ear, most CW filters have a more or less "ringing" sound. Some operators can live with it, but to me it's very distracting.

The circuit presented here is not actually a filter; hence, the name Pseudo Filter. It completely eliminates the original CW signal and its normal background noise. At the same time, it uses the decoded signal to switch on and off the output of an 800 Hz oscillator. An added feature is that while tuning, it automatically zero beats with the received CW signal.

About the Circuit

The circuit is built around two 567 tone decoder ICs. Refer to Figure 1 for the 567 pinout. The 567 contains a PLL (phase-locked loop) with a center frequency that can be set with one external series resistor-capacitor combination (R1, C2) and (R4, C7) to any frequency between 0.01 Hz and 500 kHz.

The approximate center frequency can be determined using the formula $f = 1.1/RC$, where f is the center frequency of the internal oscillator. Capacitors (C3, C4) and (C5, C6) set the capture bandwidth of the 567 IC anywhere from zero to 14% of center frequency. The values shown in Figure 3, the schematic, set the bandwidth to the widest value, which

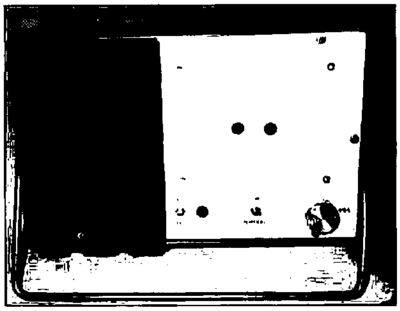


Photo. The Pseudo Filter installs easily in a speaker enclosure.

gives a "lock on" of a little over 100 Hz for an 800 Hz tone.

Since we're interested in an audio frequency, we take the input to the 567 directly from the speaker jack of the receiver. The 567 is designed so that pin 8 goes low when the input frequency is within the passband. Pin 8 is an active low output. This means it goes from near the positive supply voltage to ground through an internal open collector transistor switch when a tone is detected. When this happens, its associated LED will glow as long as the CW signal is present.

Set Up

Adjusting the two 567 center frequencies is much easier if you have access to an audio frequency generator and a frequency counter. Hook up the frequency counter to pin 5 or 6 of U1 and adjust for a center frequency of 775 Hz with R1, move your counter probe to pin 5 or 6 of U2 and set it to a center frequency of 825 Hz with R4. At these settings, the two frequencies should overlap approximately 50 Hz. If you don't have access to either of these instruments, try setting R1 to 13.33k ohms, and R4 to 14.19k ohms. On the two units I built, these values put me in the ball park. You might have a friend send you some code while you do a little "tweaking" of the two-variable resistors until you are satisfied with the operation of the unit.

Circuit Operation

In operation, audio from the receiver is connected through a 0.1 µF capacitor to the

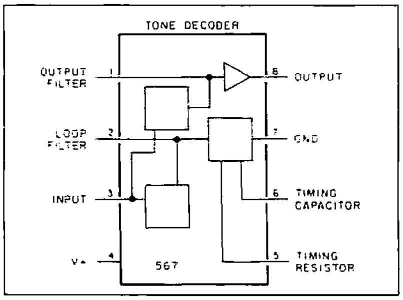

Figure 1. The 567 pinout.

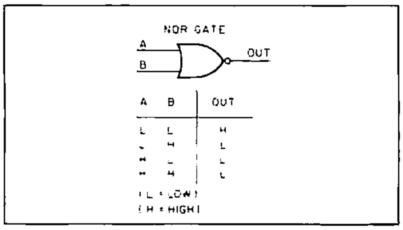

Figure 2. NOR gate truth table.

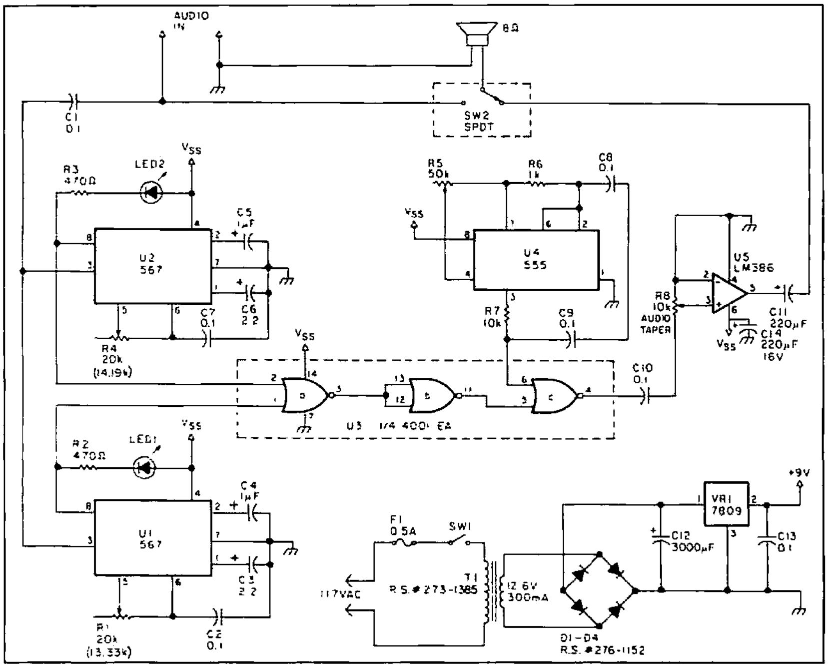

Figure 3. The schematic for the Pseudo Filter.

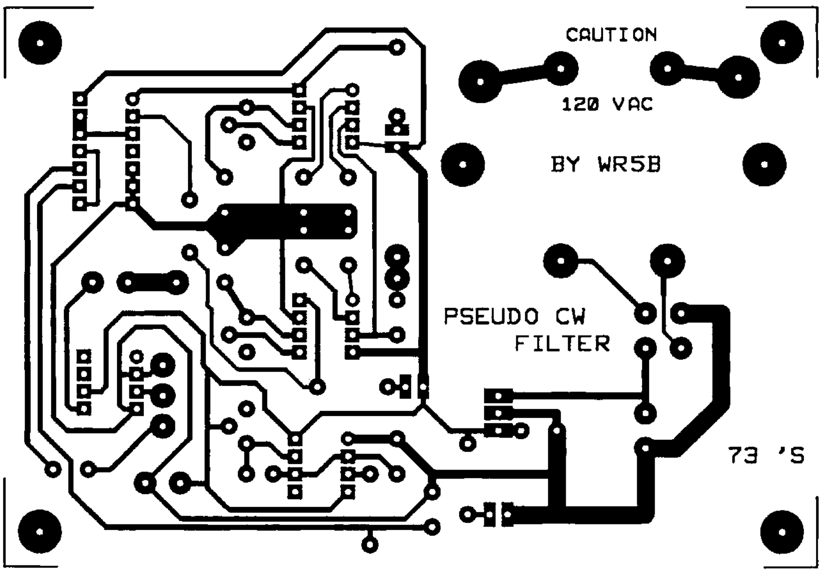

Figure 4. PC board foil pattern.

input (pin 3) of each 567 IC. When the received signal is approximately centered between the two 567 frequencies (775 and 825 Hz), pin 8 of both ICs will go low. These pins are connected to pins 1 and 2, respectively, of U3-a, which is 1/4 of a quad two-input NOR gate. Both inputs to this gate must go low for the output (pin 3) to go high. See the truth table for a NOR gate in Figure 2.

U3-b is connected to function as an inverter. An inverter is necessary because the 555 timer IC generates a continuous audio frequency, and without the inverter you would hear a steady tone interrupted only in unison with the received CW signal. Try copying code that way sometime!

The audio frequency generated by U4 is controlled by a PC mount trimmer, R5. Adjust R5 for either 800 Hz, or any tone pleasing to you. Pin 11 of U3-b is the output of the inverter. This point then goes to pin 5 of U3-c. Pin 6 of U3-c goes to pin 3 of U4, which is the output of the 555 timer, after some wave-shaping done by the RC combination of C9 and R7. In the case of U3-c, pin 5 will remain low for the exact duration of each DIT/DAH signal. The other input to this gate, pin 6, fluctuates between the high and low state 800 times per second as a result of the audio signal generated by the 555 timer IC.

Keep in mind that U3-c is being used as a digital switch. Therefore, instead of "keying" the audio oscillator on and off—its output, which is a continuous triangle wave, is simply switched in and out of the circuit 800 times per second as long as a decoded CW signal is present. Last, the output of U3-c (pin 4) is an 800 Hz square wave that is then amplified by U5, an LM386 audio amplifier.

One last thing about U3: All unused inputs of this chip should be tied to either the supply voltage or ground, so connect pins 8 and 9 to pin 7, and leave pin 10 open.

I used the 555 timer to generate the 800 Hz tone because that happened to be what I had on hand. Also keep in mind that the amplified square wave will sound just a tiny bit raspy. Admittedly, different ICs and an oscillator generating a pure sine wave could be used to follow the 567 decoders; however, as I stated, I chose the least expensive route and used the components I had on hand.

Don't be afraid to experiment. On that same subject, I also had a 7809 voltage regulator—hence the 9 volt power supply. A 5 volt supply would work just as well. But don't exceed 9 volts, as that is the maximum for the 567 IC. As you can see in the schematic, the power supply is just a standard, full-wave regulated supply.

Using the Filter

The SPST switch is wired so that you can switch the speaker between the audio as received from the receiver—standard operation—or audio only from the filter. Set the switch for standard operation, and as you slowly tune across a CW signal, either one or the other of the LEDs should start blinking in time with the received codes. Keep turning the dial slowly until the second LED starts blinking. At that point, switch to the filter audio, and the only sound you should hear is code—minus any hash or static. Also note that when both LEDs are blinking, you should be within approximately 25 Hz of zero beat. If you are answering a CQ, use only the tuning dial to zero in on the signal. If you are calling CQ, you will need to use the RIT control if your receiver is so equipped to fine-tune the answering call's frequency. Finally, there is nothing critical in wiring. If you choose not to go with a PC board (see Figure 4), you can use either wire wrap or perf board. ■

Pseudo Filter Parts List

R1,4	20k PC mount potentiometer
R2,3,9	470 ohm resistor
R5	50k PC mount potentiometer
R6	1k ohm resistor
R7	10k ohm resistor
R8	10k ohm panel mount audio taper potentiometer
C1,9	0.01 µF
C2,7,8,10,13	0.1 µF
C3,6	2.2 µF electrolytic or tantalum
C4,5	1.0 µF electrolytic or tantalum
C11,C14	220 µF/16V electrolytic
C12	3000 µF electrolytic (see below)
U1,2	567 tone decoder IC
U3	4001 quad two-input NOR gate
U4	555 timer IC
U5	LM386 audio amplifier
F1	fuse holder
SW1	SPST switch
SW2	SPDT switch
T1	117V to 12.6V; 300 mA transformer
D1–D4	full-wave rectifier module
VR1	7805, 7808 or 7809 voltage regulator IC
LEDs	red (3)
SPKR	8 ohms

It's OK to use three 1000 µF capacitors for C12. You may also use Radio Shack 273-1385 for T1, and Radio Shack 276-1152 for the rectifier module.

A blank PC board is available for $4 + $1.50 shipping per order from FAR Circuits, 18N640 Field Court, Dundee IL 60118.

Build the Brass Pounder's Keyer

A memory keyer that reproduces your true CW "fist."

by Dan Mc Cranie AA6GG

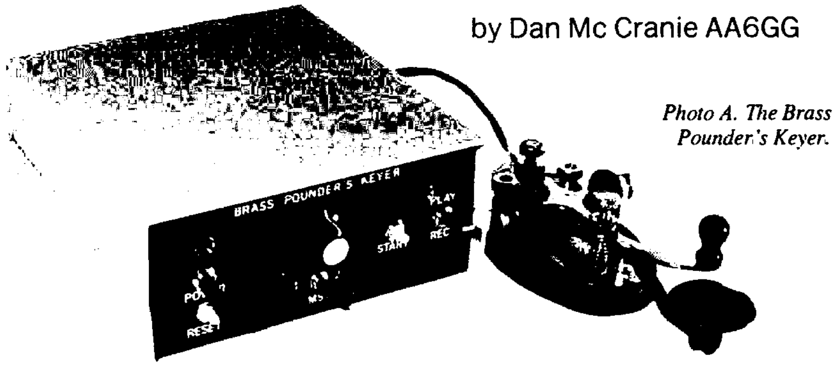

Photo A. The Brass Pounder's Keyer.

I've been in ham radio since I was 12, and I've always used a hand key for CW. My father was a chief radioman during WWII. When the family was back together after the war, he taught me the code and how to send on a hand key. There is a cadence and a distinct rhythm that you can detect when someone uses a hand key and, through the years in ham radio, I've really come to enjoy rag-chewing with other CW operators, and especially with the guys still using hand keys.

This project is a little specialized. I started it a while back with the intention of building a solid-state keyer that would accurately record the "fist" of the operator. I realized that, in doing this, I wouldn't be maximizing the storage efficiency of the semiconductor memories—but I didn't care. Memories are getting cheap enough to allow for some "programmed inefficiencies."

The Brass Pounder's Keyer is the result of this effort. In designing the controls for the keyer, I tried to make the machine as user friendly as possible. Control switches closely resemble that of a tape recorder (record, playback, start, etc.), and the machine can be left installed between your hand key and your rig without affecting normal (non-keyer) operation.

Theory of Operation

The Brass Pounder's Keyer is a digital recorder that will accurately reproduce the speed and cadence of the operator's keying. The heart of the circuit is a new type of semiconductor memory known as Electrically Erasable Programmable Read Only Memory, or EEPROM. Data is written into this memory in much the same fashion as conventional semiconductor memories. Unlike conventional memories, however, the EEPROM has the ability to retain previously stored information, even when power is removed. The EEPROM is guaranteed to hold this data for a minimum of 10 years. In addition, contents of the EEPROM data can be rewritten up to 10,000 times. By using this type of memory, power can be removed from the device at any time, and for any length of time.

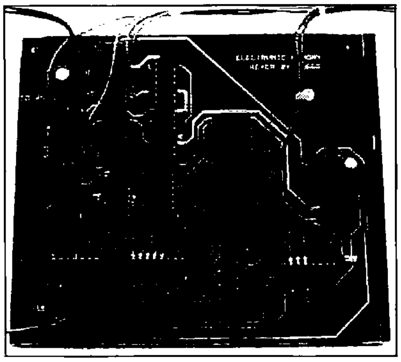

Photo B. The assembled PC board.

Brass Pounder's Keyer Parts List

Part	Description	Manufacturer
U1	NE 556 dual timer	Signetics
U2, U3, U4, U5	SN74LS93N 4-bit counter	Texas Instruments
U6, U10	SN74LS74N dual D type F/F	Texas Instruments
U7, U11	SN74LSØØN quad NAND gate	Texas Instruments
U8	SN74LSØ4N hex inverter	Texas Instruments
U9	PQ2816A 16K EEPROM	SEEQ Technology
U12, U13	SN74LS195 4-bit shift register	Texas Instruments
U14	SN74LS244 octal transceiver	Texas Instruments
R1	5.1K 10% ¼ watt resistor	Radio Shack
R2	56K 10% ¼ watt resistor	Radio Shack
R3, R8, R9, R11	10K 10% ¼ watt resistor	Radio Shack
R4	27K 10% ¼ watt resistor	Radio Shack
R5	100K potentiometer	Radio Shack
R6, R7	1K 10% ¼ watt resistor	Radio Shack
R10, R12	200Ω 10% ¼ watt resistor	Radio Shack
C1, C2, C6, C7	0.1 µF ceramic cap	Radio Shack
C3	50 µF electrolytic 35V	Radio Shack
C5	25 µF electrolytic 35V	Radio Shack
S1	DPDT miniature switch	Radio Shack
S2, S3	SPST momentary push-button	Radio Shack
S4, S5	SPDT miniature switch	Radio Shack
Q1, Q2	2N2222A NPN transistor	Texas Instruments
D1	red LED (20 mA)	Radio Shack
P1, P2	miniature phone jacks	Radio Shack

The etched and drilled double-sided PC board is available for $18 from JDM Electronics, 1974 Alpet Drive, Morgan Hill CA 95037. Add $1.50 for shipping. The U9 EEPROM is available from JDM Electronics for $7 (no charge for shipping). The complete Brass Pounder's Keyer is available in kit form (less chassis) from JDM Electronics for $70 unassembled and $85 assembled and tested, plus $2.50 shipping.

For this project, I chose a SEEQ Technology PQ2816A 16K-bit EEPROM. This is the smallest density manufactured by the company, and is available at a reasonable price. This density provides for over four minutes of recorded code. The next size larger would be the PQ2864 64K-bit EEPROM, providing for over 16 minutes of recorded code, but I felt that for most contest applications, four minutes was more than adequate. See Figure 1 for a functional block diagram of the Brass Pounder's Keyer.

Record and Playback Clocks and Modes

Two clocks are used in the keyer: a fixed frequency clock for recording, and a variable clock to allow the operator to vary the playback speed of the recorded message. The speed of the record clock is set to provide high reproduction accuracy, even at speeds up to 30 wpm. The variable clock can change the playback output speed from one-third to over twice that of the original recorded signal.

Record and play logic provides the controls necessary for either loading data into, or retrieving data from, the EEPROM. The EEPROM is a *byte parallel* random access memory device. As such, each byte (8 bits) has a unique address location in the memory. Data comes from the hand key in *bit serial* mode. The output is either a logical "1" (key depressed), or a logical "Ø" (key up).

In order to store the continuous stream of bit serial key data into a byte parallel random access EEPROM, it is necessary to do two things: First, the individual bits have to be collected and temporarily stored until a full byte is available to load into the memory; second, the address locations have to be sequentially presented to the

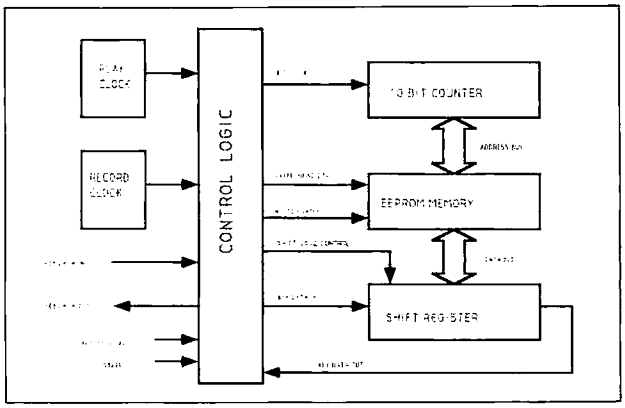

Figure 1. Functional block diagram of Brass Pounder's Keyer.

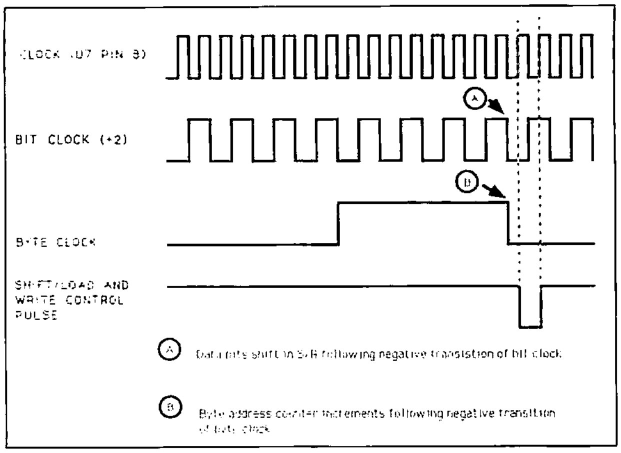

Figure 2. Timing diagram for shift/load/write control.

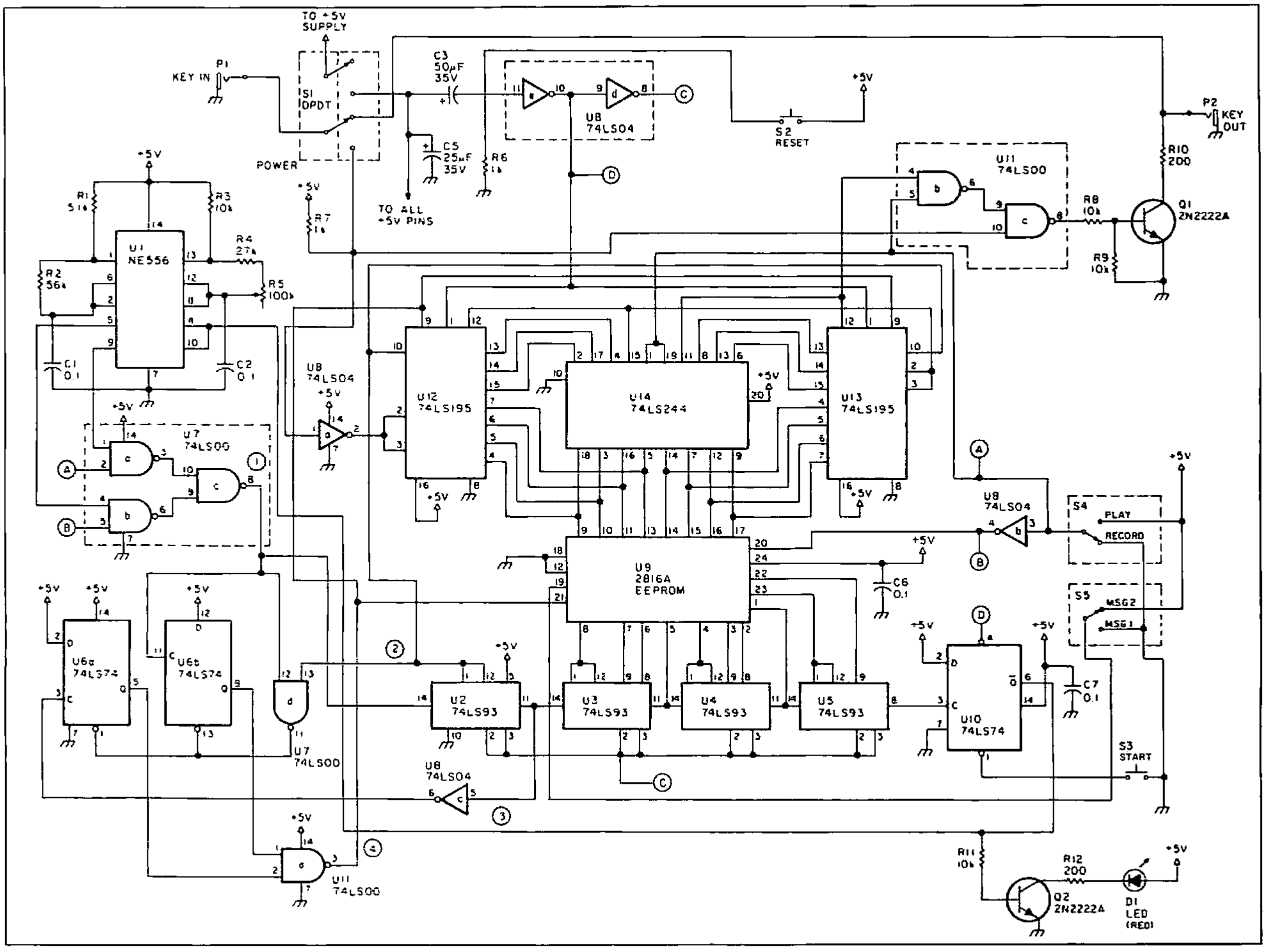

Figure 3. Schematic diagram.

EEPROM in order to seamlessly transfer the serial stream into the memory.

The first task of collecting the serial data into 8-bit bytes is accomplished by a shift register controlled by the record clock. The data recorded in the shift register is a logical "1" when the key is depressed, and a logical "Ø" when the key is open. After eight clock pulses, the shift register has a complete byte of information and is ready to be transferred to an address location in the EEPROM. This is accomplished by the record/play control logic, which momentarily inhibits shifting of any new serial data into the register, loads the contents of the shift register into one of the 1,024 memory locations of the EEPROM, and moves the EEPROM address to the next highest address by incrementing the 10-bit counter. All of this operation is performed synchronously between the end of the eighth shift register clock pulse, and before the beginning of the next shift register clock pulse. This will allow for continuous recording of the keyed data.

In the record mode, the keyer will, once started, continue to "walk" through all 1,024 address locations, recording all data presented to the input of the shift register. This takes approximately two minutes. At the completion of the 1,024th address, the clocks will automatically stop and recording is complete.

In playback mode, a reverse operation is

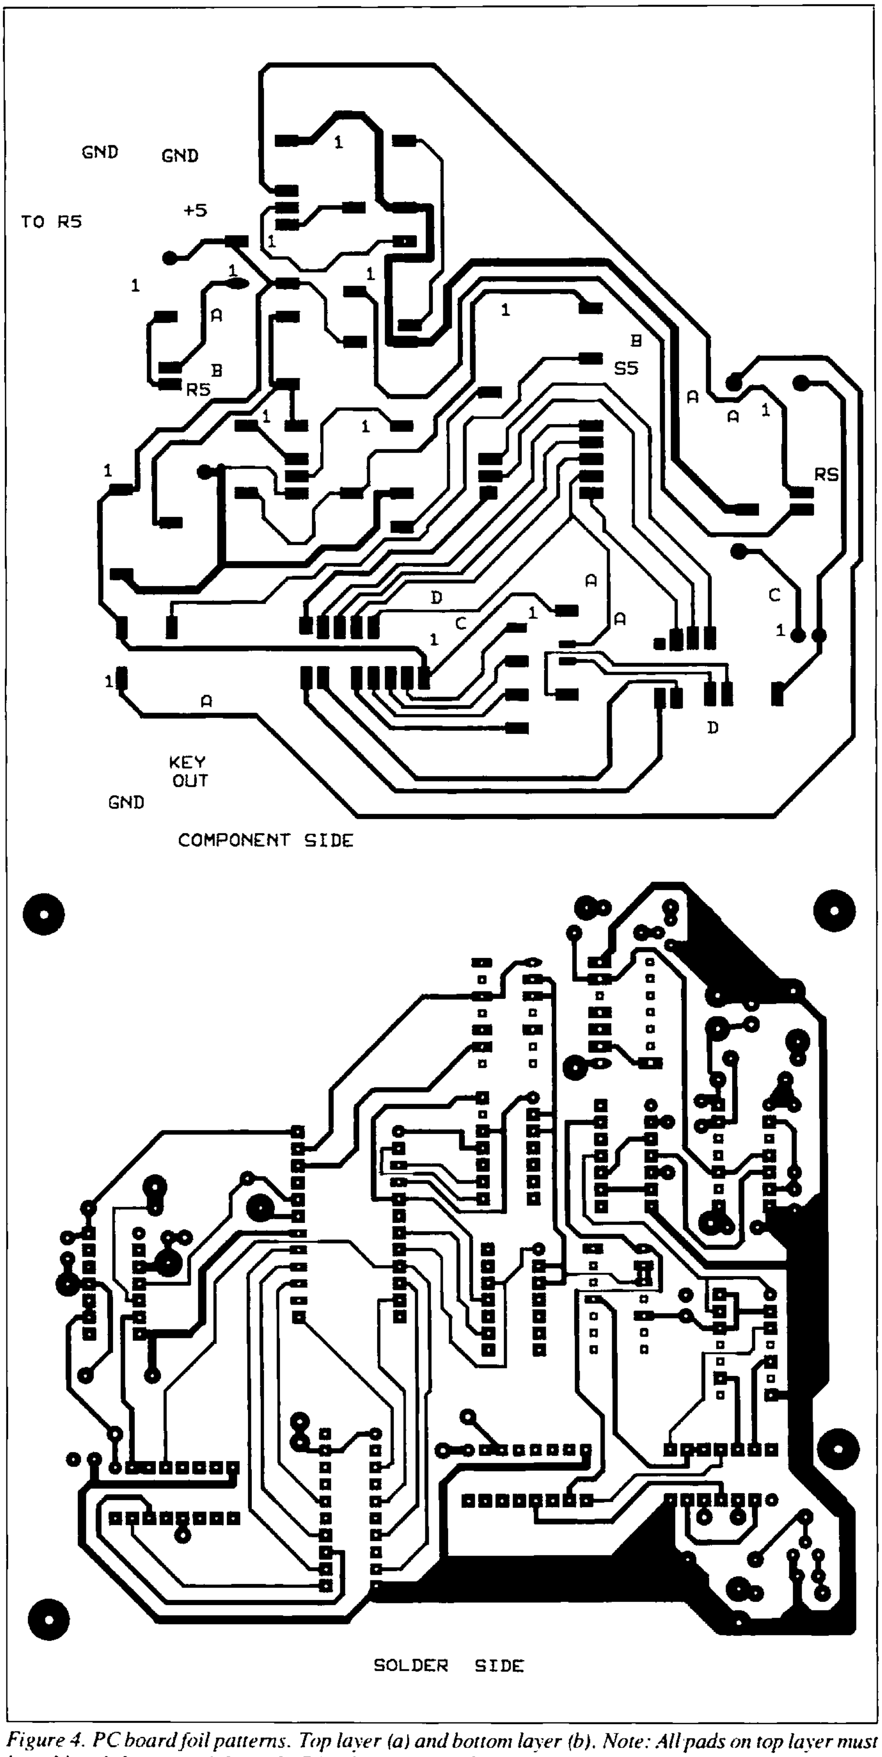

Figure 4. PC board foil patterns. Top layer (a) and bottom layer (b). Note: All pads on top layer must be soldered. Letters 'A' through 'D' indicate jumper locations.

needed. In this case, the data stored in the EEPROM will be coming out in byte parallel format and will have to be converted to bit serial. This is accomplished by first downloading the byte information from the EEPROM into the same shift register originally used to collect a byte of data from the input serial stream, and then serially shifting this information out to the key input of your rig.

In the playback mode, the play clock allows the operator to vary the playback speed. The play clock and the record/play control first transfer the contents of the first address location of the EEPROM to the shift register. This transfer is done between normal shift clock pulses, so as to make playback seamless. Following loading of the shift register, the data is then shifted out to the key-out jack. At the end of the eighth shift, the address counter is incremented and the next byte of information is loaded into the shift register. This process is continued until all 1,024 memory locations have been loaded and shifted to the key-out jack, at which time the keyer automatically stops.

Operation

The complete Brass Pounder's Keyer schematic is shown in Figure 3. Integrated circuit U1 is a NE556 dual timer that provides both the record and play clocks. The clock output of pin 5 is controlled by R1, R2 and C1. The values of these circuits provides a clock of approximately 50 Hz. R3, R4, R5 and C2 provide the variable clock with an approximate frequency range of 20 to 200 Hz. The record clock of 50 Hz was selected to provide high resolution of incoming hand-key code of up to 30 wpm, while still allowing a total of four minutes of recording from the EEPROM memory.

Clock selection, memory write and register load signals are provided by U2, U7, U6, and a portion of U8. The clock selection circuit of U7 is controlled by the record/play switch, S4. The chosen clock appears at pin 8 of U7. The clocks are turned on by control signals applied to pins 4 and 10 of U1. This is controlled by flip/flop U10. The clock starts when S3 is momentarily depressed and will run until the 1,024th count. At the end of the 1,024th count, the low-to-high transition at Pin 8 of U5 will flip U10 and stop the clocks at U1. The clocks can be restarted by momentarily depressing S3, thus resetting the U10 flip/flop.

The flip/flops and the 4-bit counter at U2 are used to provide the shift register load/EEPROM write pulse. This design was used to provide a synchronous control pulse between bit clock shifts and memory address byte shift commands. The output control pulse is present at pin 3 of U11. Figure 2 shows the timing diagram. This control pulse is applied to the EEPROM write enable signal (pin

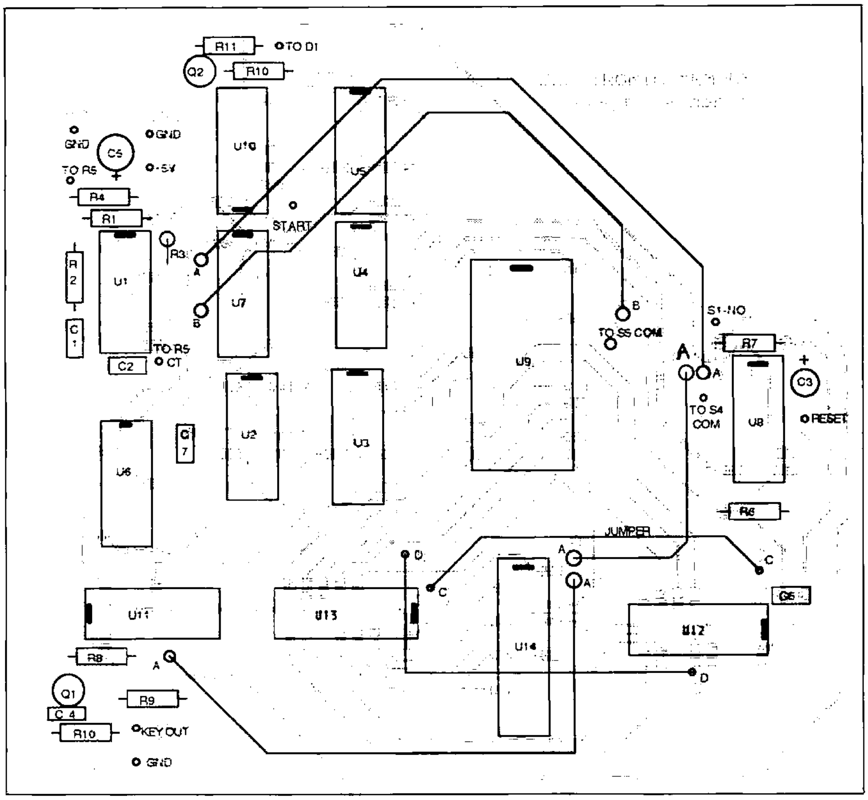

Figure 5. Parts placement (component side). Lines indicate jumper wire locations.

21 of U9), as well as the shift/register load control pin 9 of U12 and U13.

ICs U3, U4 and U5 form the 10-bit counter used to increment the address data for the EEPROM U9. The outputs of the 10-bit counter are fed into the address inputs of the 2816 EEPROM.

Data from the operator is entered into J1. The power switch, S1, is a DPDT device that allows the key to be "hard wired" directly to the key-out jack when the keyer is turned off. C3 and R4 are used to provide a momentary reset pulse to all flip/flops, counters and registers when power is first applied.

During record operation, data is fed into the first 4-bit shift register U12, and clocked by the bit clock applied from U2 pin 1. In the record mode, transceiver U14 is presenting output data from U12 and U13 in anticipation of the memory load pulse. This is accomplished by applying a low signal at pins 1 and 19 of U14.

At the end of the eighth bit clock, a write enable control pulse is generated from U11 pin 3. The EEPROM U9 then automatically latches address and data signals, erases previous contents in the addressed byte, and writes the data presented in the I/O lines to the previously specified address from U3, U4 and U5.

This record cycle will repeat until the counters U3, U4 and U5 complete 1,024 counts, at which time a low-to-high transition of U5 pin 8 will flip U10 and stop the clocks at U1.

The 2816 EEPROM (U9) is capable of storing 2,048 bytes of data, enough for four minutes of code. In the hand keyer, I elected to have a hard wire selection of two messages, each approximately two minutes long. Message selection is accomplished by S5, which is tied to the highest order address pin of U9. If your application requires a single longer message, S5 can be removed and pin 19 of U9 can be attached to U5 pin 8. In this mode, U5 pin 11 should be connected directly to U10 pin 3. These connections will allow for a single message in excess of four minutes.

During playback mode, data from the 2816 EEPROM is presented to U12 and U13, and block-loaded by the load control signal applied to pin 9 of U12 and U13. Data is then clocked out serially to J2 via the play bit clock.

The control gate of U11 pin 6 inhibits shifted data from being presented to the output during the record mode and, instead, presents the key-in signal directly to the key-out jack. The reason for doing this is to allow the operator's keying to be directly presented to the rig so that the audio tone is coincident with the operator's keying. When I first breadboarded the Brass Pounder's Keyer, I didn't have this feature, so I "heard" my keying delayed by eight-bit clock times (approximately one-quarter of a second). From firsthand experience, I can tell you that it's difficult to key code when the audio feedback is delayed by a quarter of a second! This circuit eliminated that phenomenon.

Another feature of this circuit is that it allows you to "send over" your recorded message. I found this useful, for example, when injecting RST data into my canned first response on CW QSOs.

Transistor Q1 is a garden variety 2N2222A with a small collector resistor R10, just in case I accidentally connect the output jack directly to a high-current voltage source.

The Brass Pounder's Keyer is powered by a 5 volt power supply. For my application, I connected directly to a 5 volt power supply. I also experimented with using four 1.5 volt AA Alkaline batteries, with a silicon diode in series with the load to drop the output voltage to approximately 5.4 VDC. The hand keyer consumes approximately 100 mA in standby, and about 160 in record or play. I ran the hand keyer continuously with these batteries and found that the battery life was equivalent to about 250 continuous messages. With my CW activity, I felt that I could do at least 250 messages in about three months, so I elected to use the power supply. If your usage is significantly less, and you don't have a 5 volt power supply in your shack, perhaps the internal battery pack would suit the application. Power dissipation can be reduced, obviously by removing the LED indicators. A more significant reduction can be achieved by replacing the low power Schottky devices with CMOS logic. The ready availability and extreme low cost of 74LS logic, however, was more personally persuasive when I did the first design.

Construction

For my prototype, I chose to use wire wrapping. The advantages of wire-wrapping the keyer are both speed and density. I was able to mount the wire-wrap sockets on the punched phenolic board and wire-wrap all 14 sockets in one evening. In addition, I could place the ICs side by side for maximum packing density.

The disadvantage is cost. The wire-wrap sockets ended up costing me more than some of the TTL 74LS products! The speed of assembly, however, finally persuaded me to use wire wrapping.

Another potential disadvantage (for those of us whose mind wanders from time to time during construction) is during trouble shooting. Digital circuits can behave very strangely with just one wire-wrap error, and finding the error in the rat's nest of a typical wire-wrapped board is a real challenge.

I completed the wire-wrapping project with (for me) the normal amount of de-bug headaches. To minimize construction problems for *73* readers, we decided to contract a printed circuit board design for this project, using Fred Reimers of FAR Circuits. The resulting double-sided board is shown in Figure 4. *[Note: Since the PC board doesn't have plated-through holes, it is necessary to solder the IC pins on the top layer as well, wherever a pad exists. Likewise, solder any wires both top and bottom if there is a pad on the top layer. Also be sure to run jumper wires between the lettered points as shown in Figure 5. Although the jumper wires in Photo B.*

Continued on page 32

Continued from page 28

were mounted on the bottom side (away from view), it's easier to mount them on the top side.] With the PC board, I was able to build a second unit in about one hour. . . and I didn't go blind trying to correct any wire-wrapping errors. The board level product worked perfectly. I built the board level keyer without using sockets. However, if you decide to use the printed circuit board, I recommend that you consider socketing all of the ICs.

All of the components, with the possible exception of the 2816 EEPROM (U9), should be available either at Radio Shack or at most electronics parts stores. The 2816 EEPROM is a relatively new product and tends to be available only from industrial electronic distributors, such as Anthem Electronics, Inc. For that reason, I can provide the part (see the Parts List).

Operating the Brass Pounder's Keyer

To use the keyer in your station, connect a cable between the key-out jack of the keyer and the key-in of your rig. Next, connect your hand key to the key-in jack of the Brass Pounder's Keyer.

The keyer's controls are very straightforward. For recording a message, select Message 1/Message 2, place the keyer in record mode and press the START switch. The keyer is now recording. Key in your message. At the completion of your message, wait until the keyer times out and the "complete" (red) LED is on.

To play a recorded message over the air, select Message 1/Message 2, place the keyer in play mode and momentarily press the START switch. The keyer will now play your previously recorded message. Speed of the playback is controlled by the 100k potentiometer. At the completion of your message, you may either wait until the keyer automatically times out, or depress the RESET button.

The Brass Pounder's Keyer is wired so that normal hand key operation is possible whether the keyer is on or off.

That's pretty much it. Good luck on the construction.

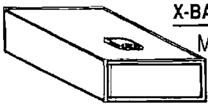
X-BAND TRANSMITTER



Miniature (2¼ x 3¾ x 1") GaAs microstrip transmitter provides 10 dBm centered at 10.525 GHz. Integrated microstrip patch antenna eliminates the need for an external antenna. Advanced matching techniques secured good temperature stability with low frequency pulling. Great for long-range testing of radar detectors, calibration of radar receiving equipment, and point-to-point communication links.

SPSM Mobile Mount

Build this reliable Hustler classic.

by David A. Clingerman W6OAL

Many of us enjoy working mobile on a variety of HF bands. An average commute to work of, say, 10–20 miles will afford us a couple of QSOs before and after the work day, and maybe even a couple at noon.

Often, the problem detouring a lot of mobile operation is the problem of how to mount the antenna. Of course, we all know the best way: ball mount on the rear deck of the vehicle. That's fine and lasts a long time, but do you really want to knock a hole in the rear deck of your new $58,000 Porsche? I didn't think so, and the housefrau probably doesn't either.

The next best way is the bumper mount. Fine for an old pickup truck, but just try to get a chain or two around the bumper of some of today's sporty autos. It's next to impossible, but not totally impossible, if the auto has metal bumpers. But, usually, you'll find they're made of some sort of high impact plastic that collapses or breaks under any sort of pressure.

On down the list is the gutter clamp. Great to hold a 2 meter stinger in place, but it will only survive your 80 meter, high power, Hustler resonator and three- to four-foot extension until you round a corner pulling about 3 G's. About that time, the entire lash-up parts from the vehicle from centrifugal force, gets airborne and spears the parking attendant a block away. Or it lies flat like a scythe, and decapitates the top of a camper. No real loss, but not conducive to your longevity.

Like I said, the gutter clip is great for VHF stingers and UHF "J's," but not for arrays of any substance. The list narrows; how about lip mounts? Trunk, hood, or whatever you can get a hold on, that wonderful little device that destroys metal with its nasty set screws. Is this the answer? Or is your Mercedes much too precious to invert-dimple for the sake of a few neat QSOs to while away the travel time?

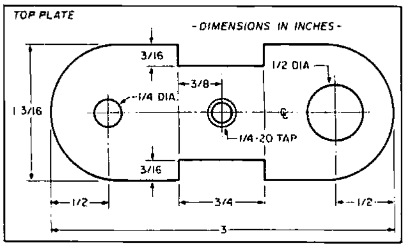

Figure 1. The top plate.

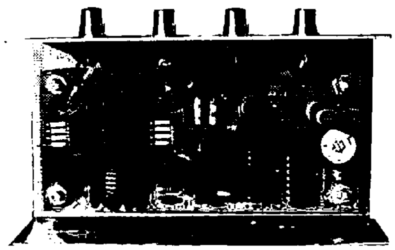

Photo A. The completed SBSM mobile installation ready to hit the road.

A Bargain Find

At one time, Hustler made a lip mount of sorts that used a compression block of cyclonic (resistant to wind damage?), high impact plastic instead of those nasty little set screws. However, when they moved their operations from Texas, they also cleaned house on a few products that weren't real movers. One of these items was the SPSM mobile mount. I picked one up from a bargain table for a dollar at R&L Electronics in Hamilton, Ohio, just because I'd never seen one before, and secondly because it was only a dollar. As things worked out, it was one of the best dollars I ever spent.

A Pontiac Fiero, as some of you probably know, has an all-fiberglass body, a difficult thing to try to find a ground point on. But the SPSM mount worked just great on the rear deck, as there arc two metal ventilators which actually attach somehow to chassis ground. Also, the SPSM can be compression-fit to a fiberglass edge, with a short piece of braid and ground clip attached to one of the ventilators.

This mount worked great for supporting my Hustler RMX 10 meter antenna and a standard stainless steel (102") CB whip, though not both at the same time.

I tired of the Fiero and purchased a van. The Plymouth Voyager has a lift-type rear door with edges that are just perfect for mounting the SPSM. The SPSM worked so well I wanted a second one for mounting my 2 meter "J" on the opposite side of the van.

Construction

I contacted Hustler to see if they had any more SPSMs, or parts still around that I might buy. They didn't have a trace, not even any drawings. Many years of special project work in the Navy taught me that if you need it and it doesn't exist, you have to build it yourself. After a few hours of sawing, tapping, and drilling, I had my very own SPSM mount. It was worth it. I feel this little mount is so versatile that I would like to share my construction with you.

The Top Plate

I acquired some strap stainless steel (1.2" wide x 0.1875" thick x 36" long) at the local ACE hardware store for about $3.50 and a couple of 1/4-20 stainless steel nuts and bolts for about $1. Using a band saw, I cut a 4" length of stainless from the flat stock. Then I rounded the corners with a bench grinder to a 1/2" radius. Let's call this item the "top plate."

On each of the long side dimensions of the top plate, and evenly centered, I used a flat file to grind in ¾" long slots to a depth of 3/16". I then drilled two holes centered about ½" from each end of the top plate. Drill one of the holes to a diameter of 0.250" and the other to 0.375". In the center of the top plate drill a 3/16" hole and tap it with a 1/4-20 die. See Figure 1.

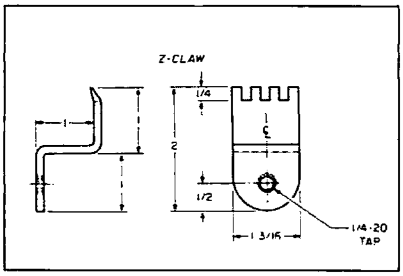

Figure 2 (a). Side view of the Z-claw. (b). Top view.

The Z Claw

I cut another piece of stainless from the flat stock. This one was 3" long. I rounded the corners on only one end to a radius of 1/2". Drill a 3/16" hole at a point ½" in from the rounded end. Then tap it for a 1/4-20 hole. I placed 1" of this end in the vise to effect a 90 degree bend using a ball peen hammer. Next, I placed the opposite end 1" in the vise, and made another 90 degree bend in the opposite direction of the first bend. This makes the device almost "Z" shaped. I'll call this piece the "Z-claw."

The Z-claw should be placed with the top plate so that the 1/4-20 holes line up. Grind the bottom side of the square end until it's sharp. Using a flat file, your next task is to make four teeth in this sharp end. To do this, you need to file three notches ¼" deep. Bend these teeth about 10 degrees toward the top plate, using the ball peen hammer. This completes the Z-claw. See Figure 2.

The Compression Block

I didn't have any hard or "cyclonic" plastic around, so I used a piece of hardwood (maple) to produce the third device, known as the "compression block." This object is drawn in Figure 3, and is probably easier to see than to describe in words. I made it using a band saw, a drill press, and a flat file. First make two saw cuts about ½" deep into the wood block (vertical sections of the channel). Then take a wood chisel to chop out the channel. If you take a look at Figure 3, you'll see a ⅜" diameter hole in the center of the compression block. Be careful to drill only to the depth shown in the drawing (⅜"), otherwise the compression block loses its compression.

I cut a ¾" length from a ⅜" O.D. steel rod and drilled it right down the center with a ¼" drill (its "Z" axis) to a depth of ⅝". About ¼" from the open end of this "cup" I drilled three holes 120 degrees from each other around the periphery, and tapped for 4-40 set screws. See Figure 4.

I used a small triangular file to score a 1/16" deep circular groove into a 1.5" long 1/4-20 bolt ⅜" from its threaded end. Next, I screwed this "prepared bolt" into the center hole of the top plate, all the way to the bolt head. Slip the little cup affair with the three set screws over the bolt, and snug the set screws into the groove so that the cup can just barely turn freely. Press the cup affair into the ⅜" diameter hole of the compression block and bottom it out. Then back out the 1/4-20 compression block drive bolt until the hardwood compression block is snugged up against the top plate.

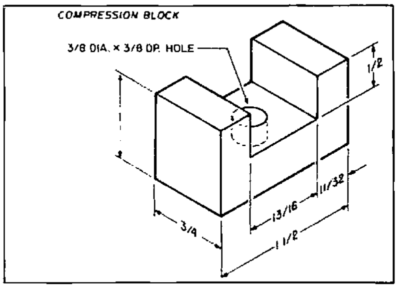

Figure 3. The compression block.

Affix the Z-claw to the top plate with a 1/4-20 bolt and snug it to the point where the Z-claw swings freely beneath the top plate. The teeth of the Z-claw, as you'll see, line up about the center of the bottom of the compression block so that when the drive bolt is screwed toward the teeth, considerable compression can occur. You can use a locking nut beneath the head of the drive bolt and tighten it against the top plate if you want. I didn't use one because I felt that, especially under tension, the drive bolt was not likely to unscrew.

Photo B. Closeup view of the SBSM mount.

Once you have affixed a small "ball mount assembly" to the top plate in its remaining hole, you will have created an SPSM just like Hustler used to make. See Figure 5.

Application

It's easy to install this device. You simply turn the Z-claw out from the compression block, and insert it under any metal or plastic lip of a vehicle. Swing the compression block/top plate assembly over the lip, align the compression block over the teeth of the Z-claw with the metal or plastic lip between, and tighten down on the compression block drive screw. The surface of the metal or plastic won't be harmed, or at least very little, by the hardwood compression block.

The teeth of the Z-claw will dig in slightly to the underside of the lip, but that will not be in view, and if metal, it can be hit with a shot of Rustoleum™ to prevent any oxidation. The teeth digging into the metal will affect a good ground at the mount. Regardless of the position in which the SPSM is mounted, the small ball assembly will always have two degrees of freedom which should allow enough latitude for almost any situation you can imagine. All you have to do now is mount your mobile antenna and mobile away.

My first test run in my vehicle to ascertain mechanical integrity entailed a trip down the

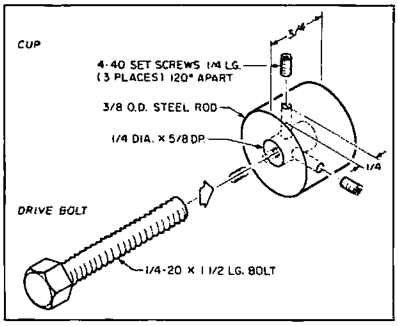

Figure 4 (a). Details of the "cup" construction. (b). The completed drive bolt arrangement.

Parts List

1 Stainless steel strap (0.1825" thick), 1.2"W x 3'L
2 ¼-20 x 1 1/2" bolt
1 Length of ⅜" steel rod
3 4-40 x ¼" set screws
1 Block of hardwood (1"H x ¾"W x 1½"L)
1 Ball antenna mount

Santa Fe Trail, south out of Littleton, Colorado, at a speed of about 60 MPH. Nothing fell off in the first few miles, so I tried a few QSOs to see if the device would also work electronically. I made a number of contacts all over the country. My third QSO was with none other than Bill Brown WB8ELK in Hancock, New Hampshire, giving a demonstration of the *73* hamshack to a group of students.

Good luck in your construction endeavors and enjoy your mobile operations with the knowledge that your antenna will remain firmly in place! 73

Tripp Lite PR-25A Power Supply and Isobar 8 GS Surge Suppressor

Tripp Lite
500 North Orleans
Chicago IL 60610-4188
Tel. (312) 329-1777;
FAX (312) 644-6505.
Price Class: PR-25A, $180; Isobar 8 GS, $115.

The PR-25A

A good 12 volt power supply is probably the most used accessory in any ham shack. Just think of all the things you call upon your power supply to run: HF rig, 2 meter gear, packet station, amplifier . . . The lowly power supply just sits there, spitting out the amps, day after day, year after year.

Unless you splurged and bought the matching 12 volt supply with your HF rig, your power supply probably looks like a cross between a billboard and a refrigerator—a big metal cabinet covered with all kinds of ominous writing. After all, it's only a power supply. Hook it up, throw it under the desk and forget it—right?

The Tripp Lite company has recently upscaled their line of power supplies. The new cabinets are an attractive charcoal color, to match modern communications equipment. Since power supplies in the 25 amp range seem to be the most versatile for amateur use (you can power everything from an HT to a standard 100W transceiver), I took a look at the Tripp Lite PR-25A (Tripp Lite offers supplies in 3—60 amp sizes, with prices starting at $38.50).

The PR-25A is housed in a sturdy cabinet and weighs in at about 20 pounds. The cabinet is well ventilated, and even during all-afternoon sessions in the shack, it did not get more than slightly warm. Two rear-mounted bolts provide connection to your power cable. These bolts are clearly marked, so unless you're not paying attention, chances of reversing your power leads are slim (it's a good idea to always check one more time before powering up your gear). A large rocker switch is the only thing (other than the company logo and model number) on the front panel, glowing red to show when the unit is turned on.

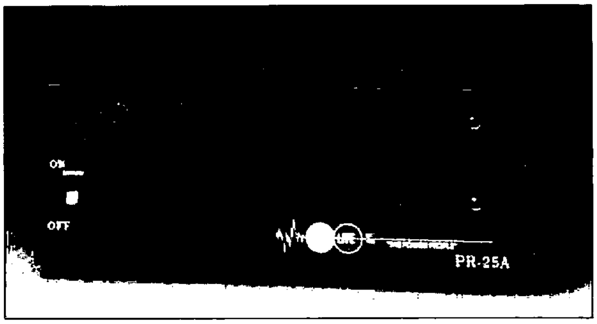

Photo A. The PR-25A power supply.

The PR-25A is rated at 20 amps continuous duty cycle, so I tuned the RTTY portion of 15 meters to see how it would measure up. Even during long transmissions of over five minutes at 50 watts output, the PR-25A never dropped below 22 amps and 13.1 volts. (Remember, even though we call them 12 volt supplies, they all provide 13.8 volts.) Even at short-duration, full-power transmissions (one to two minutes at 100 watts), the PR-25A continued to provide a minimum of 22 amps and 13 volts.

I now have the PR-25A powering my packet setup (HT and 30 watt 2 meter amp), as well as a 45 watt 2 meter mobile rig. I can run all three pieces simultaneously, and the PR-25A never misses a beat.

The Isobar 8 GS

Most of us who use computers are familiar with surge suppressors. They protect delicate computer chips from the occasional voltage surge. These surges occur everywhere from time to time, and are more frequent in rural areas (like where I live). If you plug your computer directly into your wall socket, it's only a matter of time before a line surge does something nasty—from wiping out a file or hard disk, to frying your RAM chips.

Since modern ham transceivers are really computers (your average low-end transceiver has more computing power than an entire room full of early computers), I am often surprised to see hams going to all kinds of trouble to protect their computer and then simply plugging their transceiver into a wall socket (often on the same circuit with other high current appliances). The chips inside your HF rig are every bit as susceptible to line surge as your computer, and you ought to consider using a surge suppressor.

Tripp Lite's Isobar GS line offers a couple of unique features. Tripp Lite provides its Gold Seal Warranty on the complete line of Isobar GS surge suppressors. The warranty covers not only the Isobar itself, but any equipment plugged into the Isobar. If surge damage occurs, the Isobar *and* the equipment will be repaired or replaced (contact Tripp Lite for details).

The Isobar GS also features isolated filter banks, preventing connected equipment from causing interference with each other. What Tripp Lite calls "Cascade Circuitry" allows you to choose the amount of suppression you need for various pieces of equipment. For instance, the 8-outlet Isobar provides 50, 75, 100 and 120 dB suppression.

The Isobar GS is available in 2, 4, 6 and 8 outlet models, with prices starting at $59.95. You'll feel better knowing that your expensive rig is protected from line surges. ■

David Cassidy is the Associate Publisher of 73 Amateur Radio Today.

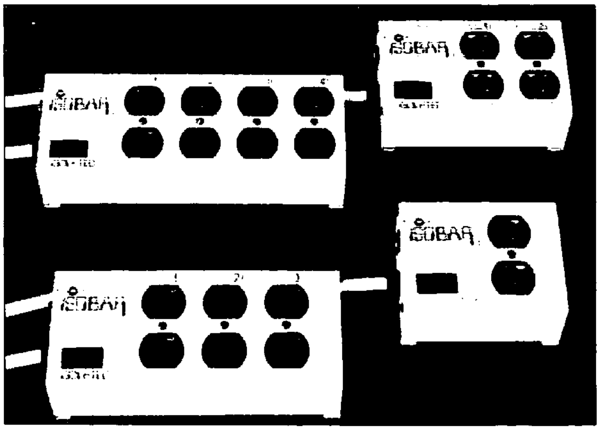

Photo B. The Isobar 8 GS surge suppressor.

Parts Substitution

A beginner's guide.

by Bruce S. Hale KB1MW/7

As I look through the latest issue of 73, a construction article catches my eye. Let's see if I have the parts. As usual, I have most, but not all, of them. And also as usual, Radio Shack doesn't have everything that I need. I could mail-order the parts, but I can't get them all from one place, and I can't put together a minimum order for any one mail-order company. Oh, well. Another project for the "if I ever find the parts" file.

Sound familiar? Maybe it's one reason why "nobody builds anymore." In the old days, they'll tell you, everyone built with standard parts, and if you needed something, you could substitute one standard part with another. Today, there are too many "special-purpose" parts. But is that really true?

There are a few special parts these days, mainly large-scale ICs. But there are also quite a few standard parts you can substitute for what looks like a special part, if you know how. My experience in building has taught me a few tricks, and I'd like to share them with you.

Can I Use This Resistor?

With resistors, the *power rating* is your main concern. You're always safe using a resistor with a power rating *greater* than what the designer specified. If the designer used a ¼-watt resistor and you've got a 1-watter, go ahead and use it. It will be a bit larger, but so what, if it saves you from waiting for mail order?

Using a smaller resistor is generally a bad idea. You could try to calculate or measure the current and power dissipation, or try it and see if you "let the smoke out of it," but you might be right on the edge of causing the part to fail. Failure might occur only after you've used the device for a while, and it could take something expensive with it!

If the design doesn't specify the resistor power rating, you can usually get away with ¼-watt parts (especially in digital circuits, 12V receivers, and low-power transmitters). If you have ½-watt parts, they're OK, too.

Resistor *tolerance* is another important parameter. Resistors typically come in 10%, 5%, and 1% tolerances. The tolerance is the amount that the value of the component can vary from the value printed on the resistor. If the tolerance is critical for a project, the design will usually specify it. If the design calls for 1% resistors, don't use 10% parts! On the other hand, going towards *better* tolerance is OK. Using a 1% resistor where a 5% value will do is a waste of money, but the device will work.

To rate parts for tolerance, manufacturers usually measure each part. It's impossible to manufacture parts that all stick to a close tolerance, but some of the parts in a given batch will be within 1%, a few more will be within 5%, and most will be within 10%. So as the parts come out of the manufacturing process, they are measured and placed in bins according to tolerance. This means that the 10% resistors will most often not be any closer than 5% of the given value. If they were within 5%, they'd be in the 5% bin! Some of the 10% parts will be on the high side, and some will be on the low side. Keep this in mind if you use 10% parts. The best way to be sure of the value is to use a digital multimeter to measure each resistor.

As for the actual value of the resistor, pay attention to the tolerance the designer specified, and use it to your advantage. If the design specifies 2.2k at 10%, the expectation is that anything plus and minus 10% from 2.2k will work. This means anything from 2k to 2.4k should be OK here. With larger value resistors, the percentage gives you an even wider margin for substitution.

Remember the series/parallel formulas you had to learn for your exam? Here's a chance to put them to use. If you need a 2.2k resistor, but all you've got is a box of 4.7k resistors, use two of the 4.7k's in parallel! That gives you the equivalent of a 2.35k resistor. If you use your imagination, you can usually come up with some combination of the values you have on hand that will equal the value you need. If you keep a good stock of some "standard" values, like 470, 1k, 4.7, 10k, and so on, your substitution job will be that much easier.

Did the designer specify a particular type of resistor (carbon-film, carbon composition, or metal film)? Usually, you can interchange types; if you have a carbon-composition resistor, and the design calls for carbon-film, you're probably OK (as long as your power and tolerance ratings are OK). If the type of resistor is important, the designer should specify it: "R1 must be a carbon-film resistor." If this is specified, don't substitute.

Pull-up Resistors

A pull-up resistor is a special case for parts substitution. What's a pull-up? It's usually one of the only resistors in a digital circuit, connected from one or more unused IC inputs to the power-supply (usually 5 volts). It "pulls up" the unused inputs and keeps them from "floating."

This is one case in which you can substitute a wide variety of parts. The designer may use 1k or 10k resistors for pull-ups. You can generally substitute *anything* within this range.

Smaller values will probably work, but they may increase the circuit's power consumption. Larger values may also work (especially in a low-power CMOS circuit), but they may also be unreliable. It's best to stay within the 1k to 10k range. As always, if you have the value the design specifies, use it!

What About This Capacitor?

With capacitors, the important parameter is the *voltage rating*. Again, it's always safe to use a capacitor rated at a higher voltage than the designer specified. A higher voltage rating just gives you a greater margin of safety. If the design specifies a 50V cap, and you have a 100V cap, use it. On the other hand, you're asking for fireworks if you use a cap with a lower voltage rating than the design calls for.

If the designer doesn't specify the voltage rating, it's best to use caps rated at twice the power-supply voltage or more. For example, using 25V caps in a 12V circuit is fine, but using 50V caps in a 150V circuit is a *bad* idea.

Here again, you can use the series/parallel formulas to combine capacitance to get the value you need. Understanding the way voltage and current divide through series and parallel capacitor combinations is a bit more difficult than with resistors; try to stick with capacitors that have at least the specified voltage rating, even if you use a series or parallel combination.

Capacitor *tolerance* is also important. There are even more kinds of capacitors than there are resistors, and the tolerance can vary widely, depending on the capacitor type. In addition, capacitors are much more sensitive to temperature, and their value may shift widely as your circuit heats up. Disc-ceramic capacitors are usually the worst. They can vary as much as 80% from the printed value!

There are some special purpose ceramic caps, however, such as the NPO (negative-positive-zero or n-p-zero, but *not* n-p-oh). These caps should be used in VFO circuits where their *temperature coefficient* (capacitance drift as the temperature varies) is the important factor. Standard disc ceramic caps will drift all over the place, which makes them unsuitable for VFO use. NPO caps hardly drift at all. If the design specifies NPO, don't use a standard cap.

What about "silver-mica" and "polystyrene" capacitors? As far as drift goes, these are almost as good as NP0 caps. If you can't find an NP0, try either of these two. But again, if the design calls for one of these three types, don't substitute a standard cap! If you have to use a silver-mica where a standard ceramic is called for, that's OK, but you're "gilding the lily" and wasting money.

Large-value capacitors (above about 2 µF) usually come in two types: tantalum and aluminum electrolytic. Both types are polarized, and must be wired into a circuit in a particular way. Some people like to use tantalum caps because they're small. They do have advantages over aluminum electrolytics—tantalum caps have lower leakage current and closer tolerances. Their actual value will be closer to the printed value, and the value will change less with temperature and time.

This makes tantalum caps ideal for RC timing applications, where you want the cap to hold a charge for a long period, and you want the circuit to be easy to duplicate. Most of the time, it's not a good idea to substitute a regular aluminum electrolytic for a tantalum capacitor. This is one of those places where the designer should help you out and tell you if it's important to use a tantalum cap. If you really can't find the specified part, go ahead and try the aluminum cap.

Bypass Capacitors

Bypass capacitors are like pull-up resistors when it comes to substitution. A bypass cap is usually connected from the power-supply pin of an IC to ground. The bypass cap gets rid of any AC spikes or noise on the power-supply voltage. You can use just about anything from 0.001 µF to 0.1 µF for a bypass cap, and any type of capacitor is fine. Most designers use 0.001, 0.01, or 0.1 µF caps because those values are easy to keep around. If you plan to build a lot of digital circuits, you should also try to keep a good stock of these values handy in your junk box.

You may also see higher-value capacitors (between 10 and 100 µF) connected from the power supply to ground near where the power connects to a digital circuit board. These are also bypass capacitors. While just about any value in this range will work, the designer may specify tantalum capacitors in a low-power circuit. Leakage current is the important factor here. Even though capacitors block the flow of DC, there will usually be some small leakage through the capacitor, and this leakage can be much higher with aluminum electrolytic capacitors. It's still very small, however, and you can almost always forget about it, especially if you are using an AC power supply. If a tantalum cap is critical, the designer should tell you.

Using Transistor Substitution Guides

Transistor selection was a thorn in my side for quite a while. It seemed like every time I wanted to build a project I had everything but one or two of the transistors. I've since learned that I could have built most of those projects with a few standard transistors.

The table shows some of these "standard" transistors. With a little creative research, you can probably substitute one of the transistors in the table for the device in that circuit you're working on.

Most transistor manufacturers (and a few parts companies) publish transistor substitution guides. You can use any one of these guides as a cross-reference to find a replacement from the table. The substitution guide will usually give you the manufacturer's standard replacement for the part. Write that number down, then look up the replacements for the transistors in the table. If the manufacturer recommends the same substitute for one of the standards, you're in business. You don't need the special part; one of the standards will do.

One other thing about transistors—you may see some deviation from the typical "2NXXXX" part numbers. For example, a PN2222 is simply a 2N2222 in a plastic case ("P" for "plastic"). Keep this in mind as you search for parts.

Manufacturer's Part Numbers

And then there are those cryptic IC designation numbers. What's the difference between a DM74151AN and an SN74151A? Each comes from a different manufacturer. Will both of them work in the same circuit? You bet. Each has the same part number: 74151A. The "baggage" in the designator is manufacturer information.

On the other hand, if a design calls for a 74LS00, and you have a 7400 IC, you might not get away with substituting your IC in the circuit. Letters in the *middle* of an IC designator tell you about the IC family. The "LS" in this part number means "low-power Schottky." There are many more IC families, but that's a subject for another article. Just remember that letters at the beginning and end of an IC number aren't usually important, but letters in the middle are.

Some Standard Transistors

Part Number	*Type*	*Typical Use*
2N3904	NPN	oscillator, switch
2N4123	NPN	oscillator, switch
2N4124	NPN	oscillator, switch
2N4401	NPN	oscillator, switch
2N2222	NPN	oscillator, switch, low power amp
2N3053	NPN	medium power amp
2N3553	NPN	medium power RF amp
2N3866	NPN	medium power RF amp (to VHF)
2N3906	PNP	oscillator, switch
2N4037	PNP	oscillator, switch
2N4125	PNP	oscillator, switch
2N4126	PNP	oscillator, switch
2N4403	PNP	oscillator, switch
2N2907	PNP	medium power switch

Catalogs, Books, and Magazines

Parts supply catalogs are usually full of information. You can use a lot of this information to help you find substitutes for hard-to-find parts. Write or call parts companies and ask for their catalogs. Some of them charge a small fee, but the catalogs are usually worth it as reference material.

Read all the construction articles you can find. Look at the schematics. You'll start to see patterns after a while. Most engineers don't re-invent the wheel—if there's a good design out there, you'll see parts of it in other circuits. Keep a file of schematics; when you find something you want to build, check through your file for similar circuits. You may see the same basic circuit using a different transistor—maybe one that's easier to find!

Join a Club

Nothing beats being able to ask someone who has more experience than you. Try to find a club where some of the members build their own gear. If no one is building, encourage them to. You may start something. Even if they're not building, most hams can tell you stories about when they did build, and you can pick up a lot of useful information.

Build and Experiment!

Parts substitution is really not that difficult. The best way to find out what works is to build! Don't be afraid to experiment; if you're not sure about something, try it, and keep a record of your results. You'll learn a lot, and you'll have fun as you learn. That's what home-brew ham radio is all about. 73

Three Bands with One Rock

Continued from page 11

was possible, but with about half the output power.

Improvements

The transmitter is a broad-band design. With appropriate output filters, you can transmit on 30 or 17 meter operation. The crystals must be fundamental mode, and no division from other bands results in the needed frequencies. Frequencies above 20 MHz are usually third harmonic types that will probably either oscillate at their fundamental frequency or be very chirpy.

Acknowledgments

The design is a mixture of many QRP rigs that have come before. Certainly no one has written more on the subject than Doug DeMaw. His *QRP Notebook*, available from the ARRL (and "Uncle Wayne's Bookshelf"), is an invaluable resource for QRP designs. *QRP Classics*, an excellent anthology of past *QST* articles, is another. It is also available from both sources.

I'd like to thank the many members of the Allen-Bradley Company Amateur Radio Club, who helped in the preparation of this project. 73

Mike Gasperi WW9X, 4529 W. Johnson Ave., Racine WI 53405.

Software for the Ham Shack, Part II

Useful ham calculations you can program yourself!

by Bill Clarke WA4BLC

With luck, you have the first part of your ham computer system up and running (if not, see Part I in the May 1991 issue). In fact, you may well have new wire antennas all over the yard that you have designed with your computer. Now it's time to add a little more to the system. This month the MAIN MENU will grow to five choices. These will be added to the first two in Part I:

3 - OHM'S LAW
4 - POWER FORMULAS
5 - EFFICIENCY FORMULA

Module Three

Make your selection from the OHM'S LAW menu, selection 3 of the MAIN MENU, and the computer will figure the unknown value for you.

Module Four

With the POWER FORMULAS menu, you can figure power output in watts. Just select the proper menu choice, and the computer will do all the math work for you.

Module Five

Just how efficient is your rig or amplifier? Merely enter the input and output powers, and the computer will tell you the percentage of operational efficiency.

Entering the Listing

Before you add program lines from this month's listing, you must first LOAD HAM1 (again, see last month's issue; if you don't have it, you can call or write the *73* editorial office for one). After it's loaded, LIST it. Then you're ready to start typing. Don't worry if some of the lines appear out of order. The computer will straighten out all the problems during the SAVE, after you finish entering the program lines.

There are quite a few lines to enter this month, so take your time and be careful. You might be well advised to enter part of the listing, save it, and take a break. Come back later, reload, and add the remaining lines.

After you have completed typing in all the lines, you must SAVE your work. Save it under the name HAM2.

Don't forget to use the modifications for the C-64 which were listed in Part I of this series.

Listing for HAM2

C-64 Users: Don't forget to make the modifications listed in Part I of this article series.

393 DEF FNA(P) = INT (P*100+.5)/100
```

(Continued)

Using the New Program

LOAD the new program by typing LOAD "HAM2" and pressing ENTER. When the computer signals READY on the screen, type RUN and press ENTER.

The next thing you should see is the MAIN MENU for your new HAM SYSTEM. It should show five selections: ANTENNA DESIGN MATH, TRANSMISSION LINE MATH, OHM'S LAW, POWER FORMULAS, and EFFICIENCY FORMULA.

Next month, in Part III of this four-part series, you'll add modules six and seven: RADIO HORIZONS and OHMS TO RESISTOR COLORS to your ham shack software. ■

You may reach Bill Clarke WA4BLC at RD#2 Box 455-A, Altamont NY 12009.

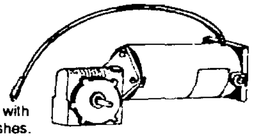
HIGH-TORQUE GEAR MOTOR



Everest & Jennings 24 W series High torque, permanent magnet gearhead motor with replaceable brushes. Rated for 24 Vdc; operates fine on 12 Vdc. We think these were originally built for wheelchairs. 1/2" dual shaft on final drive.
Ratings: 12 Vdc 1.7 amps 220-290 rpm
24 Vdc 2.0 amps 445-470 rpm
Motor is 5 3/4" long X 3" diameter with 3.125" square mounting bracket. Gear box is 3.37" long X 3.2" wide. Shafts extend 0.75" to either side of gear box. 9.5 lbs.
CAT# MOTG-16 $25.00 each

HALL EFFECT SENSOR

Microswitch # SS41 - Tiny, solid state switch reacts instantly to proximity of magnetic field. Operates at extremely high speeds, up to 100 kHz. Case size: 0.12" X 0.17" X 0.06" thick. 4.5 Vdc to 24 Vdc supply voltage. 10 ma. sink type digital output. Operating gauss - 15 to 40. P.C. leads.
CAT # HESW-2 75¢ each • 10 for $6.50
100 for $60.00 • 1000 for $500.00

SWITCHES

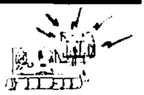
Pushbutton Switch

SMK Manufacturing 0.47" square black pushbutton. SPST normally open. 4 p.c. pins for mounting. Ideal for low current switching applications. **CAT# PB-29**
5 for $1.00 • 100 for $15.00

Rotary BCD Switch

EECO # 2310-02G - BCD 10 position rotary switch. DIP configuration fits in standard 8 pin I.C. socket. Right angle style. Screwdriver actuation. 0.42" cube. **CAT# RDIP-2**
$1.75 each • 10 for $16.00 • 100 for $145.00

FLASH ASSEMBLY

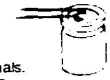


This NEW compact flash assembly comes from a U.S. manufacturer of cameras. Unit operates on 3 Vdc and measures 2 1/2" X 1 1/4". Ideal for use as a strobe, warning light or attention getter. Complete with instruction on how to wire.
CAT# FSH-1 $3.75 each 10 for $35.00

3 1/2" DISKETTES

Quality, double-sided 3 1/2" diskettes. These diskettes were recorded, but never used. Flip the write-protect tab to off position and use for your own data storage at a fraction of the cost of new diskettes.
CAT# DTS-1 $1.00 each • 10 for $9.00

Special New Reduced Price PHOTOFLASH CAPACITOR



Rubicon CE photoflash capacitor. 0.79" dia. X 1.1" high. These are new capacitors that have been prepped with 1.4" black and red wire leads soldered to the terminals.
210 Mfd 330 Volt **CAT# PPC-210**
$1.25 each • 10 for $11.00 • 100 for $100.00

TOLL FREE ORDER LINES

73 Review

by Dick Goodman WA3USG

SWISSLOG Version 3.66

A complete QSO tracking system in one fast software program.

Frank Greenhalgh KD2LL
10 Robbins Ave.
Amityville NY 11701
Tel. (516) 598-0011
Price Class: $75

Computer logging programs have certainly proliferated in the last 10 years. Until I found Swisslog, I never really deemed them exciting enough to explore in detail. Over the course of the last 20 years I have maintained my log in a variety of ways. During the pre-computer era of the early 1970s, I used the official ARRL logbooks. They worked out pretty well. They had all the necessary fields for mandatory information, such as call, date, time, signal report, etc. The back side of each page was blank, making it excellent for free-form remarks. The only problem was that after the log contained about 200–300 entries there was no efficient way to look up a particular QSO unless you knew the date. So I went to 3" x 5" cards for a while (one for each QSO). What a pain!

Eventually I switched over to an MSDOS machine and tried a variety of commercial logging programs, but none quite suited my needs. I ended up using "DBASE III Plus" as a development system, and finally "Clipper" (a DBASE program code compiler) to write my own logging program. You can spend hours programming up your own system or make it easy on yourself and get a copy of SWISSLOG.

More Than Just Logging

SWISSLOG is not just another logging program. It is a complete amateur radio QSO tracking system with its own versatile reports generator/formatter, statistics generator, worldwide prefix/call library, beam heading routine, grid locator, awards tracking system, propagation prediction program (with graphic display of signal path), Grayline program, and other features too numerous to mention. SWISSLOG can be used as a full-featured logging program by the novice computer user, but its features really shine when the user has rudimentary computer skills.

The documentation provided with SWISSLOG is just about the best I have ever seen. Version 3.66 comes with a 102-page, professionally-bound reference manual, plus a 33-page addendum. It is clear, concise and includes beautifully printed screen dumps and screen layouts. It is written to be a tutorial as well as a reference manual. There are also tutorial files included with the SWISSLOG program itself. This documentation, along with "READ.ME" files, will enable new computer users to come online with this program very quickly. Users who have had generic query language programming experience (e.g. reports generator in DBASE III) will find this program almost intuitive. The ability to sort on any field and generate your own record selection criteria based on any combination of fields is quite impressive.

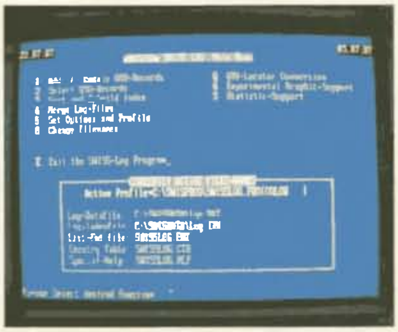

Photo A. The SWISSLOG main menu.

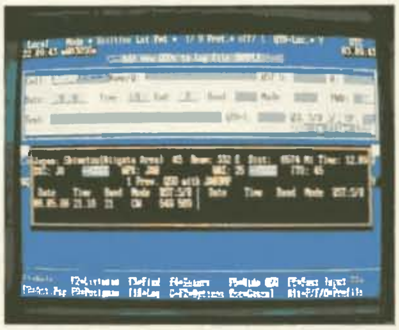

Photo B. Menu for Option 1, "add/update QSO records."

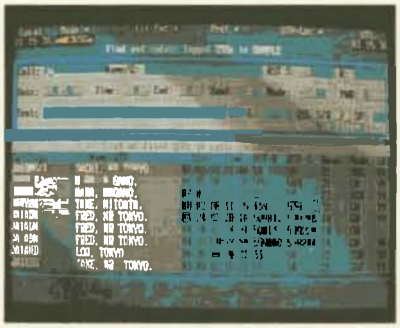

Photo C. Sequential list of all "JA" contacts currently logged.

SWISSLOG is also quite fast. Included on the distribution diskettes is a sample log which contains over 1,200 entries. It took a maximum of about 15 seconds to sequentially search through this entire database and generate on-screen reports from my specified record selection criteria. It should also be noted that SWISSLOG uses index files to control the sorting of the database. Even when the total database becomes much larger than the current 1,200-plus entry size, the time to sort by callsign will not increase once the index file has been built. This was a great limitation on older and less sophisticated logging systems. Another advantage is that an index file takes up much less space then a duplicate data file sorted in the desired sequence. Using index files also makes field seeks (e.g. finding QSOs by callsign) effectively instantaneous.

The reference manual clearly documents installation of SWISSLOG. The installation is totally automatic and takes about five minutes. SWISSLOG requires 512K of memory, and it will run on monochrome or color systems with DOS version 3.1 or higher. I would recommend a hard drive, but a system with two floppy drives will handle up to 2,000 QSOs. This review was conducted on a Comp-U-Add 286 running at 20 MHz with a

Photo D. Progation prediction map.

VGA display. The default color configuration for all SWISSLOG screens is, in my opinion, striking! The color scheme can also be changed by the user. Liberal use is made of pop-up windows. Virtually the entire program is menu driven. To enter the system, simply type "SWISSLOG" and press ENTER>.

SWISSLOG's Offerings

The first time SWISSLOG is executed, the user will be prompted to enter a "personal profile." This consists of the latitude and longitude of the QTH, the offset to UTC, display type (color/mono), and several other parameters unique to the user. This is all requested via a friendly menuing system and only has to be done upon initial program installation. Any of these values may be changed later if desired. The SWISSLOG main menu will follow, as shown in Photo A.

Please keep in mind that because of the sophistication of this program, this review will cover only the main points. The capabilities and versatility of this system are limited only by the imagination of the user.

Option 1, "Add/Update QSO Records," is almost self-explanatory. Upon selecting this option, the user is presented with a menu similar to that shown in Photo B. From here you may enter new QSO data or, by using the appropriate function key as identified on the bottom of the screen, call up existing logged entries to be viewed and edited. Index files are used so the search is instantaneous, regardless of the database size. The order of data entry on this screen may be changed from Option 5 on the main menu to best suit the user's needs. For example, the callsign may be prompted for first, followed by the date and start time, then signal reports and other applicable fields. There is also a contest mode that checks for dupes on each band and notifies the user with inverse video and an audible signal. A sequence number can be kept updated for each QSO for contests that require it. Finally, the propagation prediction feature may be called up from here. This displays a world map with the propagation path displayed, and estimated signal strength on each available band (See Photo D).

Option 2, "Select QSO-Records," presents a sub-menu. This allows the user to select QSO records via the SWISSLOG query language, sort records in any sequence, print, list to the screen or a file those selected records, and browse/update the selected records. Fields selected by the user may also be globally updated or deleted. Additional log files may also be created from this selected data. Reports generated may be formatted as desired.

Option 3, "Sort and Rebuild Index," allows the regeneration of the SWISSLOG index file in callsign sequence. The "Sort" function will physically move the actual QSO records in any sequence of your choice.

Option 4, "Merge Log-Files," allows the user to add the QSO records of one log file to the currently active log. This function enables several log files to be used in parallel, and is particularly useful in contests where a unique file would be required for dupe checking, etc.

Option 5, "Set Options and Profile," allows the user to customize SWISSLOG. Names of files that are to be used, data relevant to your station (e.g. lat, long), definition of the most used options, input sequence of QSO fields, initial values of each QSO record, printer control sequences, display mask attributes, and QSO entry window size and placement may be specified. The color scheme of all SWISSLOG screens may also be modified from this option.

Option 6, "Change Filenames," allows the selection of the active log from all available log files.

Option Q, "QTH-Locator Conversion," will convert from latitude and longitude to grid square, or vice versa. It also provides beam headings and distance from your station.

Option G, "Experimental Graphic-Support," allows tailoring of station and environmental parameters, such as antenna type and height (for each band) and sunspot number. This is used with the propagation prediction feature.

Option S, "Statistic-Support," generates reports on the user's progress on getting DXCC, WAZ, ITU and WPX awards. These reports are beautifully formatted and would be of great assistance to the devoted contester.

SWISSLOG has numerous other features not touched upon in this review. One important capability is the ability to import ASCII data into the database. This makes it possible to transfer data from other logging programs, or programs such as DBASE III, into SWISSLOG. The table which contains country/prefix/geographical coordinates may also be updated as prefixes or other related data changes. Finally, SWISSLOG may be made resident and popped up from within other programs. The configuration options of this feature are diverse and should satisfy most applications where memory allocation could be a problem.

It is impossible to describe the capabilities of SWISSLOG in the space allocated here. I can say with absolutely no reservations that this is the best logging program that I have ever seen, and I am now using SWISSLOG myself! 73

BARTER 'N' BUY

Number 14 on your Feedback card

Turn your old ham and computer gear into cash now. Sure, you can wait for a hamfest to try and dump it, but you know you'll get a far more realistic price if you have it out where 100,000 active ham potential buyers can see it than the few hundred local hams who come by a flea market table. Check your attic, garage, cellar and closet shelves and get cash for your ham and computer gear before it's too old to sell. You know you're not going to use it again, so why leave it for your widow to throw out? That stuff isn't getting any younger!

The *73 Flea Market*, Barter 'n' Buy, costs you peanuts (almost)—comes to 35¢ a word for individual (noncommercial) ads and $1.00 a word for commercial ads. Don't plan on telling a long story. Use abbreviations, cram it in. But be honest. There are plenty of hams who love to fix things, so if it doesn't work, say so.

Make your list, count the words, including your call, address and phone number. Include a check or your credit card number and expiration. If you're placing a commercial ad, include an additional phone number, separate from your ad.

This is a monthly magazine, not a daily newspaper, so figure a couple months before the action starts; then be prepared. If you get too many calls, you priced it low. If you don't get many calls, too high.

So get busy. Blow the dust off, check everything out, make sure it still works right and maybe you can help make a ham newcomer or retired old timer happy with that rig you're not using now. Or you might get busy on your computer and put together a list of small gear/parts to send to those interested?

Send your ads and payment to the *Barter 'n' Buy*, Donna DiRusso, Forest Road, Hancock NH 03449 *and get set for the phone calls.*

Also let us be your accessories and complete radio store. BNB998

Get on the WARC Bandwagon

You can still enjoy good DXing, even as propagation conditions decline.

by Drayton Cooper N4LBJ

Even though Sunspot Cycle 22 has shown some marked idiosyncracies lately, the consensus of opinion is that the number of spots will soon be showing a marked decrease once again. To any avid user of our higher frequency bands (20 meters and above), that means declining conditions on long-haul paths, and increasing frustration over the scarcity of good openings to faraway places. Looking ahead two or three years to the bottoming out of Cycle 22, there is a ray of hope for those of us who enjoy DXing: The WARC bands are now all in place, and one of them in particular should ease the need for a DX fix.

The WARC Bands

The WARC bands are the "new" bands, assigned to amateur radio as a result of the last World Administrative Radio Conference, in 1979. These relatively small slices of spectrum space were handed to us over a period of 10 years, with the last one, 17 meters, opened for U.S. operators less than two years ago.

For the first time in our history, we will be facing the bottom of a sunspot cycle with more choices of frequencies than we have ever enjoyed before. If you have not tried the WARC bands (and there is a surprisingly large number of hams who haven't), this article will introduce you to them. And, along the way, even hams familiar with these frequencies will find a few tips for better using them.

30 Meters

The granddaddy of the WARC bands is 30 meters. It's an all-digital band, meaning that you dyed-in-the-wool CW fans have a home now, just as you did years ago when 40 meters was King of the Air.

The 30 meter band runs from 10.100 MHz to 10.150 MHz, and in that 50 kHz you'll hear nothing but CW, AMTOR, RTTY and HF packet since, with few exceptions, voice modes are not allowed in this band.

Clustered near the lower end of 30 are the CW operators. If you're not the holder of a 35 wpm code proficiency certificate, don't feel that there's no place for you on 30. The vast majority of fists you'll hear on the lower end of 30 are sending at a comfortable rate of

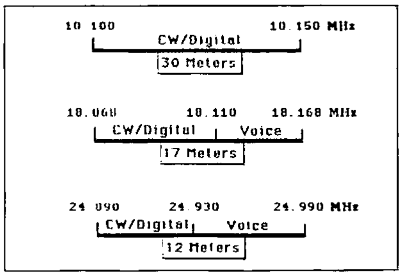

Figure. Frequency chart of the WARC bands.

15–20 words per minute.

The propagation on 30 is not necessarily what you would expect it to be. Many hams felt it would combine the best of 20 and 40, and to a degree it does.

One of the charms of 30 meter operation is that it can exhibit some very unexpected surprises. For instance, you may be rag-chewing with a friend in the 350-mile range, sign with him, and suddenly hear a station calling you from another continent!

DX possibilities are generally quite good on 30. One reason for this is that all hams are on fairly level ground on this band as far as power is concerned. Most countries have set limitations on power output on 30m (250 watts is generally the maximum), and antennas on this band continue to be primarily fairly simple ones.

12 Meters

The next WARC band to be opened to U.S. hams was 12 meters. Nestled about halfway between the very popular 15 meters and the quixotic 10 meters, 12 meters runs from 24.890 to 24.990 MHz. The mode plan on 12 divides the band at 24.930 MHz: Below that point, communication is limited to the digital emissions; above it, SSB reigns supreme.

If you're a DXer trying this band for the first time, look for stations around 24.935 on SSB. In the early days of 12 meters, many DXers settled in a few kHz up from the lower SSB band edge and, out of habit, they continued to center in this area.

On CW, however, it seems that there is no fixed DX window. Both stateside and foreign stations are found throughout the lower portion of the band.

Propagation on 12 meters seems to be much more like 10 meters than 15. This means that the band is often apparently dead, with few, if any, signals coming through. However, there might be plenty of ionospheric support for communications if someone would put out a CQ.

The 12 meter band does seem to be underoccupied. There was an initial rush of stations trying it out, but now the number of operators using it seems to have leveled off considerably, so there is practically no QRM.

Because of its proximity to 10 meters in the radio spectrum, conditions on 12 are often a "delayed" mirror of 10. For instance, from the East Coast, operators on 10 meters look west late in the afternoon for contacts with Oceania.

Sometimes, just as a rare Pacific island becomes readable in the east on 10, the band folds, and the station is lost. Dropping down to 12 meters at this time, the East Coast ham would still be able to hear signals from the same general area that he had on 10. However, because 12 meters is principally a daytime band like 10, he might get only another 30–60 minutes of use before it, too, closed down.

17 Meters

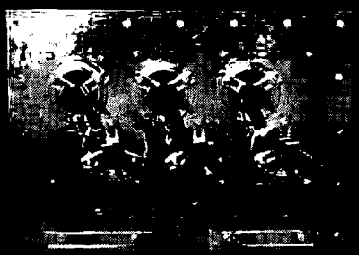
The "sleeper" in the WARC bands appears to be 17 meters. More and more, this band seems to be catching on with hams around the world. Band occupancy on 17 is now quite good, and QRM is becoming an everyday occurrence.

This band runs between 18.068 MHz and 18.168 MHz, with the dividing point between CW and SSB (in the United States, at least) at 18.110 MHz. Above that point, SSB is permitted; below it, the digital modes are exclusive.

There is no reduced power limitation on 17 (nor on 12, for that matter), and if you want to run the legal limit, you may. However, few stations on 17 run much more than 100–200 watts. In all likelihood, though, this is not because of any altruistic motivation! Until quite recently, most commercially available linear amplifiers either would not resonate on 17 meters, or would do so only very inefficiently. As the manufacturers redesign their gear to load up on 17, you can expect more

NEW

GROUNDED COAX ENTRANCE PANELS



• Easy Installation
• Weatherized Ports
• 1/2" to 1 5/8" Coax

CIRCLE 258 ON READER SERVICE CARD

and more high power stations to appear there.

If you listen on 17, you are in for some real propagational surprises. One day the band may be filled with signals from both the United States and Europe; a few hours later, signals from half a world away may be the only ones you hear!

Just recently, the USSR Antarctic station, 4K1B, was heard here on the East Coast at 579–599 levels, while only a few kHz away the USSR Arctic counterpart, 4K2OIL, on Franz Josef Land, was coming through at equally good signal strengths. These stations were almost 12,000 miles apart, yet both were being worked by hams across the United States.

Another eye-opener on 17 is the strength of long-path signals. Stations in Australia and New Zealand generally come through on the short-path (i.e., direct path) into the United States during the early morning hours on 17 meters.

Later in the day, however, you can often work these same VK/ZL stations with even better results by using the long-path. The same phenomenon appears on 20 meters, at generally the same hours, but the long-path signals on 17 usually seem stronger than they do on 20.

DXing

Thus far, the IARU (International Amateur Radio Union) has banned contest operations on all three of the WARC bands. For those hams who do not care to engage in the RF mayhem of contesting, the WARC bands offer a respite on those winter weekends when it appears that the rest of the world's population is sending nothing but "CQ Test."

Little by little, however, DXpeditions are discovering the new bands, particularly 17 meters. This is a knife that cuts both ways. The presence of some of the more recent DXpeditions on 17 has allowed many hams to have a taste of working a really rare one. In some cases, the appearance of the expeditions on the WARC bands gave many an opportunity to work the DX they would not have had on the other bands because the pile-ups were smaller, and were far more disciplined.

This brings up another point about the WARC bands. Much of the raucous and discourteous operating habits found in such abundance on the established bands is generally nonexistent on the WARC frequencies, even in the midst of DX openings. Why this is the case would be a good topic for a sociologist or psychologist to explore. But so far, the vitriol and hostility which have marred our reputation around the world is simply absent on the WARC bands.

Antennas

For many (probably most) hams, the antennas of choice for the WARC bands seem to be the ones they already have! However, some time spent on putting up a good antenna for 30, 17 and 12 will pay off in huge dividends.

In preparation for writing this article, I recently spent several hours on 17 meters, listing the various antennas I heard in use. Far and away, the most-used antenna appeared to be either a 75 meter or 40 meter center-fed Zepp. Not far behind came the G5RV variation on the same theme, followed by loops of various configurations. Only a very few stations seemed to be using resonant, multi-element, rotatable antennas. The ones who were using them, though, "owned" their frequencies!

I expect my experiences with antennas for the WARC bands are typical. When I first used these bands, I loaded my "all-band Zepp" on 30 meters with a T-match tuner. The results were good, and I was satisfied. Then I heard a W8 who was using the same rig I was, but was feeding it into a 2-element rotary. He and I often worked the same DX stations back-to-back, but he usually got a 589 or 599 from the DX station, compared to my 569. Lesson learned!

A compromise antenna will work well on the WARC bands, but a dedicated, resonant antenna will work far better. There are several dual-band yagis now available commercially for 17 and 12. I can highly recommend the 2-element 12/17 beam available in kit form from Gary Nichols KD9SV, owner of SV Products, 4100 Fahlsing Rd., Woodburn IN 46797; but there are others available on the market that are probably just as good. Cushcraft now produces 3-element trapped 12/17 beams and monobanders for the WARC bands. Also, a number of manufacturers offer WARC add-on kits for their existing antennas.

Rolling your own for the WARC bands, especially for 17 or 12, would be a worthwhile project, too. Boom lengths are certainly reasonable (mine is only 8') and aluminum tubing for the elements can be found in most hardware stores. And, there is certainly no reason not to use "thin wall" conduit (EMT tubing), which was the staple item for years for nearly all home-brewed beams of earlier times.

There have been several articles published in the amateur literature on yagi designs for 12 and 17 meters. One of the best of these appeared in the July 89 issue of *Radio Communication* (the journal of the Radio Society of Great Britain). This design uses three elements on a fairly short boom, with a split driven element. The advantage to this type of construction is that the driven element can be fed directly with the coax, so you won't need to build a gamma matching device.

I hope that this primer on WARC bands has piqued your curiosity, and that you'll be interested enough to give the new bands a try. As I've pointed out, each of them has its own appeal, especially as we look at deteriorating propagation on the established bands, and the increasing QRM as more and more stations "move down" because of the decline in sunspot activity. A good antenna for the WARC bands is in reach of every ham, and with one, you'll find a new world of operating pleasure awaiting you.

Why not hop on the WARC bandwagon now? 73

Hunting for the Gold

"This Time It's Our Turn!" That's the headline of the bulletin I received, describing what will probably be the first international amateur radio direction finding (DF) competition on US soil. It may also be a prelude to T-hunting becoming an event at the Olympics!

The bulletin was from the Friendship Amateur Radio Society (FARS). It came with a lengthy letter from John White K7RUN. I hurried to the phone and was soon speaking with him. The good news was that the upcoming contest was "for real." The bad news: There was little time to round up our best "world-class" DFers.

Sister Cities Starts It

Portland, Oregon, is a sister city to Khabarovsk, in Asian USSR. Khabarovsk has 650,000 residents and is 480 miles northwest of Sapporo, Japan. In the spring of 1989, the Portland Amateur Radio Club (PARC) was invited to send a team to the first Sister Cities Friendship Radiosport Games (SCFRG-89) in Khabarovsk, to begin September 25 of that year. The Soviets would have two teams competing. There would also be a team from Niigata, Japan, another sister city to Khabarovsk.

PARC was up to the challenge, and sent five locals to the Games. They were: Richard Fredrickson WAØDIM (Photo A), Dave Wright N7MYO, Kevin Hunt WA7VTD, John White K7RUN, and Rene Berblinger KX7Z.

In addition to the foxhunt, the Games included high speed CW and HF "round robin" DX events.

In the USA, we think of a T-hunt as an outing in the family car, van, or jeep, with perhaps a hundred feet of "sniffing" at the end.

Elsewhere in the world, however, the fox is a completely different "animal." In Europe and the Far East, foxhunting is an athletic event. Successful competitors are skilled at DFing and wilderness orienteering, plus they can withstand the rigors of a course that may take them several miles.

The PARC participants knew little of what lay ahead. They knew nothing about the DF gear they would be using to find the fox, because it was to be supplied to all the teams by the Soviet hosts. Talk about a home-court advantage!

Foxhunting, Soviet Style

There are no "appliance operators" in the USSR, because no commercial ham gear is made there. Russian hams "roll their own" or convert surplus military rigs. Evgeny Stavicky UWØCA, Chairman of the Khabarovsk Territorial Radiosport Federation (Photo B), built his own state-of-the-art HF transceiver, complete with LED readout, from salvaged parts. The Soviets cannot buy ham and DF gear from the US and Japan because the ruble is not an international currency.

K7RUN described his introduction to Soviet-style foxhunting: "The DF receivers were the only piece of manufactured ham equipment I saw in the whole stay there. They were quasi-military devices, with no S-meter. You had to listen in the earphones and judge the signal strength.

"The foxhunt was held on two meters. They have very little activity on that band in general there—no repeaters. Antennas were all four-element yagis, with a bit of a strange pattern. They were built to be collapsible. The elements were curved steel like a tape measure, which held shape when extended but could be folded up.

"The target transmitters put out MCW. The receiver was not a superhet design. It was the TRF type, solid-state, broad, and very difficult to tune. There was no BFO, but it had a quencher circuit that interrupted the received signal at an audio rate to create a tone.

"The five DF units for our team were not very uniform. The antennas tended to have two nulls on the back, one much deeper than the other."

As Murphy would have it, the day of the DF competition was the only day of rainy weather during the team's stay in Khabarovsk. "We all had the look of drowned rats," says K7RUN. By world radiosport standards, the event was held on an abbreviated course, with only three transmitters.

The total course was about a mile. The Soviet teams placed first and second, as expected. The PARC team came in third, followed closely by the team from Japan. Shortest individual time for the course was just under five minutes. Longest time was 44 minutes.

After the Games ended, there were visits to the homes of Soviet hams, a group boat ride on the Amur River, picnicking, and hours of happy ham and non-ham talk. Just as in the USA, hams in the USSR are a cross section of the country. UWØCA is a professor of music and a piano teacher in a girls' school by day. He runs a club ham station for his school.

The US hams were given Soviet ham tickets upon arrival. Some of the Russians wanted to get operating privileges for future visits to the USA. There were enough VEs in the US delegation to hold an exam session in Khabarovsk, but the exams had to be given in English. Nevertheless, Mikhail Zavarukhin UWØCN passed all the elements for his US Extra class license and is now AA7CH.

Photo A. Cameras flash as Dick Fredrickson WAØDIM leaves the foxhunt starting ramp at the first Sister Cities Friendship Radiosport Games in 1989.

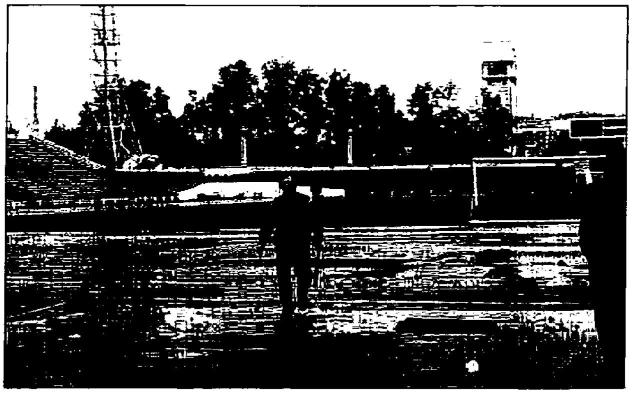

Photo B. Piano teacher Evgeny Stavicky UWØCA sprints to the finish line after completing the foxhunt course in Khabarovsk, USSR.

Let's Have a Rematch

Soon it was time to go home. But the hams of Portland were not about to let it end there. They soon established FARS, a nonprofit corporation, in November 1989. A few months later, UWØCA and UWØCN visited Portland to help promote FARS, plan further events, and demonstrate radiosports (non-DF) in the Goodwill Games. Evgeny passed his Technician exam during his time in the USA.

That brings us to the present, and the Friendship Radio Games of 1991 (FRG-91). Under the leadership of WAØDIM, FARS is putting on a three-ring circus of ham radio competition beginning May 30: foxhunting, CW sending/receiving, and HF contesting.

The FRG-91 DF contest is being held in Forest Park, said to be the largest park in any city in the world. In keeping with world-class European competition rules, five hidden transmitters will be scattered around the park. Each contestant's score will be his or her time to find the five rigs, in order, and return to the starting point.

Transmitters will have CW identifiers, and be activated in sequence for one minute each. In addition, there will be a continuous homing transmitter on a separate frequency to guide the contestants back to the start/finish line. The complete course will be 3.75 miles or less.

FARS is providing DF equipment to entrants selected for the team competition. A limited number of individuals will be allowed to compete independently, but they must provide their own gear. Maps of the course will be provided in advance.

As you might expect, the Portland area will provide most of the US foxhunters for FRG-91, but the organizers want other areas of the country to be represented, too.

As of this writing, it looks like Albuquerque, New Mexico, and the Los Angeles area will be represented, at least.

The Soviets and Japanese will be present again, of course. A dozen hams from Khabarovsk will be there, along with Gene Shulgin UZ3AU, technical editor of *Radio*, a Soviet ham magazine. In addition, a team from Vancouver, Canada, may compete.

Foxhunting at the Olympics?

FARS has even bigger ideas for the future. K7RUN says, "We are pushing, as is Eastern Europe and the USSR, to make foxhunting an Olympic sport, at least as a demonstration. A set of games is being planned for Leningrad in several months that will be used as a springboard for this."

Hats off to the hams of Portland for bringing world-class woodland foxhunting to the USA! Watch future "Homing In" columns for the results of FRG-91. For more information about FARS and FRG-91, write to PO Box 13344, Portland OR 97213. 73

Houston TX 77083

Station Enhancement

Only 15 years ago most of the antennas and accessories in an amateur satellite station were home-brew or made from kits. Today the reverse is true. All the necessary gear can be purchased, but many amateurs prefer to build their own preamp and antenna-polarization control box.

Some satellite antennas come with polarization-control units, or can be purchased as an option. A few mast-mounted preamps come with control boxes, but most do not. In many cases, stations will have at least four individual control units for the antenna-mounted 2 meter and 70 cm preamps and the polarization relays on the antennas.

Newcomers may ask why mast-mounted preamps and polarization-control devices are necessary. Sometimes they are not, but amateurs who have worked with the satellites for a few years know the advantages of having them. Such systems are especially useful for the high-orbit satellites, like AMSAT-OSCAR-10 and AMSAT-OSCAR-13, where distances and signal attenuation are many times greater than for the low-orbit satellites.

The schematic in Figure 1 shows a simple control box that incorporates all the necessary control functions with the least number of parts. Most polarization relays and remote preamps operate from 12–14 volts DC, so any 12 VDC regulated supply capable of one to two amps will provide power. If the supply is home-brew, install a fuse with the appropriate current rating on the AC line. Commercial supplies should already have a fuse.

The purpose of the simple design is to give an easy-to-read and meaningful indication of relay or preamp operation. The first LED after the power supply is simply a power-on indicator, while the second shows that the 12 VDC in-line fuse is intact. The current meter provides the simplest means of monitoring the relays and preamps with a true indication that the correct current is being consumed by the device or devices that have been activated.

Most polarization relays draw about 100 mA. When a line is energized, the expected reading should show on the meter without change. Loose connections are immediately apparent if the reading varies. A short causes spikes and may even blow the fuse, but no power supply damage occurs and the problem can be quickly resolved by tracing the line to the antenna. Corrosion over a period of years is usually the problem.

Mast-mounted preamps can draw as little as 50 mA up to a few hundred mA. Before they are installed, each polarization relay and preamp in use should be tested, and the current measured, to characterize nominal consumption. Labels on the control box for each line are helpful. In a typical configuration with 100 mA polarization relays and 50 mA preamps, the current meter shows 300 mA when all the remote items are activated. The extra line could be used for a 10 meter preamp in the shack.

Cable to the remote relays and units should be good quality rotor cable or old coax runs. Avoid cheap rotor cable—it will deteriorate with outside exposure to the elements. Eight-conductor cable is the best since the extra conductors can be connected in parallel for the ground return. The 1,000 pF capacitors on the control box output lines keep stray RF energy out of the system. A terminal strip on the back of the box provides an easy way to disconnect lines for troubleshooting problems that can develop with time.

My control box has been in operation for over 10 years. In that time, I've installed several different antennas and tried as many preamps. I detected deteriorating cables, isolated faulty relays, and replaced the current consumption labels on the front of the box whenever a new remote device was installed. Of all the hamsat shack accessories, the control box has been one of the most useful.

What Is AMSAT?

Created in 1969, AMSAT is a worldwide organization of amateur radio operators dedicated to educational and ham-related activities via satellite. The goal is to build and support satellites for open use by amateurs everywhere.

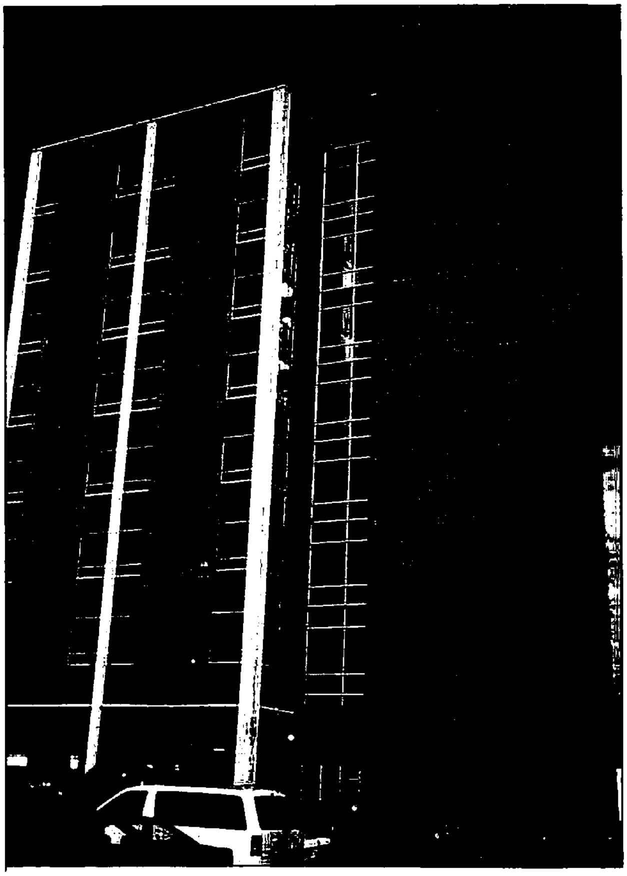

Photo A. AMSAT's main office is here in the Washington, DC, area.

Current operational amateur spacecraft include: AMSAT-OSCAR-10, UoSAT-OSCAR-11, AMSAT-OSCAR-13, UoSAT-OSCAR-14, AMSAT-OSCAR-16, DOVE-OSCAR-17, WEBER-OSCAR-18, LUSAT-OSCAR-19, FUJI-OSCAR-20, AMSAT-OSCAR-21 (also known as RS-14), RS-10/11 and RS-12/13.

Project OSCAR of California began the tradition in 1961 with the launch of OSCAR-1. (OSCAR stands for Orbiting Satellite Carrying Amateur Radio.) In recent years, international AMSAT groups have adopted location designators. For North America, this nonprofit educational organization is called AMSAT-NA.

Photo B. Martha Saragovitz, AMSAT Secretary, takes another call at (301) 589–6062.

Photo C. A Phase 3 Hamsat spaceframe greets visitors as they enter the AMSAT office.

Where is AMSAT?

The easiest way to answer the question, "Where is AMSAT?" is to point skyward to the incredible array of ham satellites.

AMSAT-NA is a volunteer association with very few paid employees. It has offices in Silver Spring, Maryland

HAMS WITH CLASS

Carole Perry WB2MGP
Media Mentors, Inc.
P.O. Box 131646
Staten Island NY 10313-0006

Introduction to KF6PJ

There are so many teachers and instructors doing so many innovative and exciting things with amateur radio! Many school teachers and amateur radio instructors have written in to share their ideas with others. In upcoming columns, I'll feature schools where the creative uses of amateur radio are being used in the classroom, and I'll highlight successful recruiting methods used by amateur radio clubs across the country.

In April 1989, I had the pleasure of meeting a teacher, Dave Reeves KF6PJ, and his wife Bernadette, at a NASA Educator's Conference (for the Magellan launch at the Kennedy Space Center) in Orlando, Florida. Dave and I, being fellow hams, immediately found each other. We've been corresponding ever since, exchanging ideas and classroom experiences. It's a personal pleasure for me to showcase the wonderful work he's been doing with amateur radio at the Chaminade College Preparatory School in California. The following is the article Dave prepared with his students for this column.—WB2MGP

High School Club Station WA6BYE

Dave Reeves KF6PJ: Imagine a Space Age high school science classroom at Chaminade College Preparatory in West Hills, California. This week the space shuttle *Columbia* on mission STS-35 is in orbit, carrying the Astro-1 observatory and SAREX (Shuttle Amateur Radio EXperiment). A large TV screen in the classroom displays live video of the earth from the shuttle's payload bay via K6KMN's Mount Wilson ham TV repeater. Another large screen computer terminal displays the location of the space shuttle as it orbits the globe. Several students are studying plots of solar panel currents and temperature data they have just obtained from the DOVE ham satellite.

The students at Chaminade became interested in space science when they participated in the 1985 SAREX experiment and got an SSTV picture from astronaut Tony England WØORE on the space shuttle *Challenger*. With the help of physics teacher Dave Reeves KF6PJ and engineer Mike Tweedy KA6SPT, the students have maintained an ongoing space science program using the OSCAR amateur radio satellites.

Now, Ben DeWit and Keith Butler listen for the first sounds of the packet radio telemetry beacon as DOVE pops above the horizon. Their computers point the satellite antennas and capture today's telemetry data. On the NASA TV, an excited scientist in Huntsville reports data from a distant galaxy showing high energy radiation from matter "waving good-bye" just before being swept into a black hole. Chaminade senior Rima Mulokas looks up from a worksheet on the efficiency of the Microsat solar cell, gazes at the live pictures of earth from the shuttle, and says, "I don't believe this. This is blowing my mind!" Teacher Dave Reeves smiles in agreement.

Articles from *The Los Angeles Times* and *Daily News*, a stack of video tapes with no less than nine network and local TV news reports, and the ARRL SAREX video, tell the story of the past five years of the students' involvement with ham radio in space.

Encounter with Ron Parise WA4SIR

"Star Students—Students Tap Short-Wave for Long-Distance Reach to Shuttle." This *Times* headline reported the latest exciting SAREX event. The physics class, with the help of 11-year-old Jimmy O'Donnell N6VYA, talked with astronaut Ron Parise WA4SIR on the *Columbia*.

Because of the Astro-1 astronomy mission, the shuttle didn't pass over the United States during normal school hours; volunteer relay stations in Brazil and Australia helped out. The morning of our contact, Larry Etter N6MBJ used Frosty Oden N6ENV's "Valley Repeater" to call AMSAT so that we could listen in on Ron and a couple of students. The students were Jim Fonte KK9T in Indiana and Dan Blackburn K5ZCO in Texas. This session was relayed through PY2BJO Junior, in São Paulo, Brazil. Our students listened to the tape of the contact to try to anticipate what their own contact was going to be like.

On the evening of December 4, our students excitedly gathered on the lawn near their classroom to talk to Ron themselves. Adam Wahab used the computer display set up by Anthony Fredericks and Eric Sunde to show the 100 spectators and the press that the shuttle was now coming in over the Indian Ocean, and would soon be within range of the VK6IU tracking station in Western Australia.

Photo A. Eric Sunde, Melissa Parker, and computer group leader Anthony Frederick watch Columbia's *progress on TRACKSAT.*

Photo B. Nicole Newman displays the orbital gyrations of DOVE while John Fenger and Andy Casciato watch attentively. The Astro-1 BBXRT (the "trash can") is on the TV screen.

Photo C. SAREX team Dave Reeves KF6PJ, Jim O'Donnell N6OYF, Melissa Parker, Jimmy O'Donnell N6VYA, Robert Nomura, and Lori Jadon, after making contact with Ron Parise WA4SIR on board Columbia *on December 4, 1990.*

Jimmy O'Donnell accessed the phone number to the "bridge" in West Virginia. Bill Tynan W3XO, at the W5RRR club station at the Johnson Space Flight Center in Houston, was soon on the line. Three other schools also joined the bridge. Allen Miller N7NHM from Rigby Jr. High School in Idaho, Dale Harris WA5OAP from Las Cruces, New Mexico, and Ron Curry WA4GSS from Lawrence County, Kentucky, were checked in and ready. Three relay stations in Australia were clearly heard: Gorden VK6IU in Western Australia; Graham VK5AGR in Adelaide; and Art VK2AS in Sydney.

The shuttle popped above the horizon near the western AMSAT tracking station in Australia, and Ron Parise was ready for Jimmy O'Donnell's question: "If you saw aliens or a UFO, would you try to communicate with them, and if so, how?" Ron replied: "You know, we've been looking out the window for the Soviet space station *Mir*. They're up here with us, too. We have 12 people in orbit right now. They're not exactly a UFO. I don't know what I'd do if I saw a UFO out the window. Probably just wave." Alesia, another student asked: "How far in space can you see?" Ron: "Well, looking out in space we can see to the edge of the universe with our telescopes. That's a long, long way. With your eyes, looking down on the earth, we can see about 800 miles in any direction. We are just coming up across Shark Bay on the western edge of Australia. If I were looking out the window, I could see all the way to Central Australia, and all the way north to Java. We can see a big piece of the earth, and I'll tell you, it's really beautiful from up here."

Andy took the mike next, and asked: "What do you think might be beyond the quasars?" Ron: "That's an interesting question. Maybe we'll be able to shed some light on that with this mission. I'm not sure exactly what quasars are, but they appear to be very early prototypes of galaxies that we see now, but we're seeing them so far back in time because they're so far away. Their light took a long time to get here. And before that, before the beginning of the universe, we're not sure what happened."

At this point, Ron was passed to Wess VK5AGR in Adelaide. Wess asked: "How many stars can you see from orbit that are not visible from earth?" Ron: "It's not that we can see more stars, but that we can see ultra-violet light. UV light gets filtered out by the atmosphere, and we can't see it from the ground. So that's what's important to us here with these telescopes." Ron said that it is hard to see

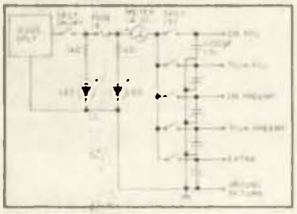

Figure 1. OSCAR antenna polarization and external preamp control

on the north side of Washington, DC and Paris, Texas, northwest of Dallas, but the satellite construction and support programs are active wherever AMSAT volunteers live

There is no well-defined central point for satellite work, although activity can always be found in the vicinity of AMSAT Vice President of Engineering Jan King W3GEY. Jan presently lives in the Boulder, Colorado, area

A visit to the modest AMSAT office in Silver Spring, Maryland, hints at the broad activities of the organization. Here is where memberships and software orders are processed A visitor can find satellite drawings, correspondence, and models dating back to the early days of the organization.

Several of the original organizers of AMSAT live within a few hundred miles of Washington, DC, but over the years members of the Board of Directors have come from most points within the U.S., as well as from Canada, England and Japan Today's board members are from Colorado, Maryland, Michigan, New Jersey and Texas.

The success of this organization, with a satellite program that many governments cannot match, is due to the passionate dedication of the membership. The AMSAT field organization has over 130 Area Coordinators and Regional Coordinators around the country who volunteer their time to answer questions, give talks and present demonstrations at hamfests. Their "pay" is the satisfaction of helping others enter a truly remarkable facet of the amateur radio hobby.

So, the next time you're asked "what" or "where" is AMSAT, just point up 73

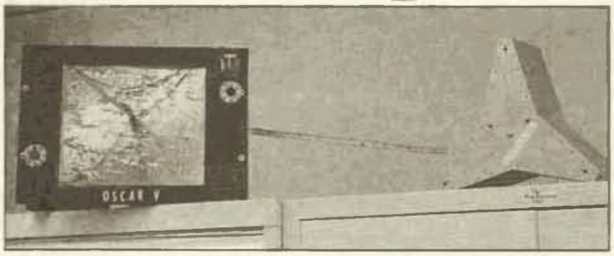

Photo D. A model of AMSAT-OSCAR-5 sits quietly on an office cabinet.

NEW From Micro Computer Concepts RC-1000 REPEATER CONTROLLER

• Autopatch
• User Programmable CW ID, Control & User Codes & Timeouts
• Intelligent CW ID • Auxiliary Outputs • Easy to Interface • Remote Base/Tape • Reverse Patch • Tailbeeps • 12 VDC Operation • DTMF Decoder with Muting • Telemetry • Control RX • Response Tones • Programmable COS Polarities • Detailed Application Manual with schematics • 90-Day Warranty

Wired & Tested w/manual $239.95

 Continued from page 56

stars out the window with the lights on inside the shuttle.

Next, Michael in Dale Harris' group in Las Cruces, New Mexico, asked: "What are the benefits of the UV Telescope you are taking up, compared to the Hubble?" Ron explained that the Astro-1 UV has a wider field of view and a broader spectrum range than the Hubble. Heather, also in the group, asked: "What kind of emergency methods do you use in case of danger, such as lack of oxygen?" Ron said that even if a small hole were to be punctured in the shuttle, they would be able to maintain their oxygen supply long enough to get safely back to earth.

By now, control had been passed to VK2AS in Sydney, and Brian, in Ron Curry's group, asked the last question: "What do you expect to find concerning the super nova of 1987?" We are not sure of Ron's answer because our recorder ran out of tape at this point Even so, the astronomy lesson and the SAREX contact were a smashing success for amateur radio!

There were lots of little problems during the contact. Signals were lost at both ends several times. We missed an important "over" and doubled with Ron, as our radio had accidentally been switched to low power, and our audio was scratchy into the repeater Several other schools had trouble with audio feedback into the radio, and the keys on touch-tone got pushed once or twice. Once, Ron lost his footing and floated away from the radio for a moment. Yet the communication was exciting, and every school got a chance to speak with Ron. Many other repeaters across the country were able to call in, listen to the contact, and share it with hams interested in SAREX.

SAREX has brought space science alive at Chaminade College Preparatory and in many other schools across the country. Amateur radio can help capture the imagination of the new generation. There is no doubt that we will one day be using ham radios to talk to astronauts on the space station *Freedom*, the moon, Mars, and beyond!

Twenty-Five Years!

This brief description of the classroom events of the past week illustrate the benefits of getting teachers, kids, and schools involved in ham radio. For my students and me, ham radio has always played an important role. Our Chaminade High School Club Station, WA6BYE, has been on the air for 25 years.

The club's two stations use almost every mode and band available: HF, VHF, RTTY, SSTV, ATV, satellite, and packet. Mike Tweedy KA6SPT designed and built the club a computer-controlled satellite antenna rotor system. Our 105-foot HF tower can be seen for several miles

My students and I have shared many memorable ham radio experiences. We have worked the entire globe on 20, 15, and 10 meter DX, worked military phone patch traffic during the Vietnam War, and emergency traffic during the Mexico City earthquake. We have been a Scout-o-Rama event station. We have worked with OSCARs-8/10/12/13/17/19 and RS-10/11. We've talked with students in Carole Perry and Joe Fairclough's classrooms in New York City.

Our most thrilling experiences have been the 1985 SAREX, when we obtained a great SSTV picture of Tony England W0ORE, and our 1990 SAREX conversation with Ron Parise WA4SIR.

Microsat—An Ongoing Experiment

With the launch of the four Microsat satellites, we had the opportunity to fully integrate ham radio into our physics classes. I asked Maria El-Zik, a senior in the physics class, to explain how the project works

Maria El-Zik: "I am one of the seniors currently involved in a new experiment. We are tracking the Microsat satellites which have been orbiting the earth for about a year. We are currently focusing on DOVE, the most attainable and readable of the four Microsats. All the students in Dave Reeves' two physics classes have specific jobs related to tracking DOVE.

"Today, for example, the people in charge of predictions were at work first. They were in the lab early this morning in order to learn DOVE's passing times for today. This was done with two computer programs: TRACKSAT and ORBS. Then they charted the passing times on the blackboard in our physics room.

"The operators were at work next. People like Ben DeWit and Keith Butler track DOVE on the receiver during lunch. They obtained 15 pages of data from the pass today, a good average. Soon other operators will be tracking an evening pass.

"Joe Hafferty and Paul Brukiewa created a full-scale model of DOVE, complete with antennas that are white on one side, black on the other (made so the satellite rotates with the sun's natural power).

"The next group is vital to our experiment They give meaning to the data obtained by the operators by analyzing it and plotting it on graphs. They do all this by using computers. This takes quite a while, but the results are impressive We have been able to analyze DOVE's movements by studying their graphs. We would also like to learn something more about the greenhouse effect by comparing the infrared readings taken above land to those out on the ocean. We are all extremely interested in the result of the analysis because we believe the greenhouse effect is the major ecological problem of our day

"Finally, it is our turn. As the public relations group, we write to various places, either obtaining information about the Microsats or telling the scientific community what we are doing.

"All of us enjoy tracking DOVE. It is so much more meaningful to learn physics in this way. And we are not only learning the standard science, we are learning about computers, data analysis, and writing skills. This is an experiment we will all remember for a long time." 73

RTTY LOOP

Amateur Radio Teletype

Marc I. Leavey, M.D., WA3AJR
6 Jenny Lane
Baltimore MD 21208

Portable RTTY

With the approach of Field Day, I sat back and reflected on just how that impacts on RTTY. On the surface, I get this mental image of a Model 15 in a sedan chair, being transported to the wilds of the outback. When Field Day was conceived, that was *exactly* what portable RTTY was all about, unless you had a Mighty-Mite or the like. But not today!

Sure, the hardy among us might still lug along a conventional teleprinter, and there are those well-equipped clubs with vans sporting every conceivable mode of communication; but how about the ham wishing to operate on a digital mode without breaking his back?

For the purposes of this discussion, I would rather not concern myself with the transmitter, receiver, or antenna. Somehow I have confidence that these topics are adequately covered elsewhere in this magazine. Let's just direct our attention to the RTTY end of the table. To this end, I would like to examine:

- RTTY interfaces and terminal units
- Keyboard and control units
- Printer and hard copy devices

Decoding the RTTY Signal

Compared to the old tube-type terminal units that were popular when I started in RTTY, the RTTY/packet modems currently represented are marvels of miniaturization and power conservation. Sophisticated controllers, such as the AEA PK-232 and Kantronics KAM, are small enough to pack along, and will run on the same power supply as the radio.

For those who choose to roll their own, TNC or demodulator boards are available from a variety of sources, as well as some schematics presented in this column in the past, which would enable construction of a compact RTTY terminal unit.

Those whose intent is packet operations only, and who are in search of the ultimate in compactness, might do well to look at the Heath HK-21. This little marvel allows packet operation with a TNC about four by three inches, small enough to fit in a shirt pocket.

Packing the Keyboard

Here we have quite a variety of materials to choose from, but our latitude depends on one critical factor: the availability of AC power. If the portable station is run on conventional AC power, either from a generator or the utility company, available input/control devices range from dedicated RTTY terminals to power users' bit crunchers.

Considering space and weight, a case could be made for some of the simple, all-in-one style computers. Such widely used, inexpensive, compact devices as the Color Computer, Commodore C-64, and the like can make excellent interfaces, especially with a smart terminal unit providing much of the logic related to digital communication.

Where freedom from AC power is a must, notebook computers shine. While I have yet to caress one with my own hands, one hot computer in this market, by many experts' accounts, is marketed under three designations: the CompuAdd Companion, the Sharp PC-6220, and the Texas Instruments TravelMate 2000. A 80286 running al 12 MHz, with 1 meg of RAM, a 20 MB hard disk, and a VGA resolution LCD screen, this little wonder comes in under $3,000, a remarkable price. And at 4.3 pounds, and the same size as a sheet of bond paper, not too much to carry, either.

I might also mention the Zeos Notebook, a similar bargain. If you have access to an 8088 based portable, and want to use it, fine! But I, for one, might caution against investing in one at this time, with all the new technology on the horizon—and even in the foreground.

Hard Copy, Anyone?

Once again, let's put the big page printers, and even conventional computer printers, aside. Portable printers are available, and if you want one, quite a few will fill the bill.

Canon's BJ-10e is an ink jet that produces near laser quality print from a notebook sized box. Priced under $500, this four pound wonder comes with battery or AC power options, as well as a cut-sheet feeder.

For about the same money, Eastman Kodak produces the Diconix 150 Plus, which handles sheet or fanfold stock, in a compact 10.8" x 6.5" x 2" package. With a weight under four pounds, including batteries, it's hard to resist.

One other option to pack into your bonnet: There are several programs around which redirect all printer output to a disk file. With a big enough hard drive, such a program can provide a record equivalent to paper, without the need to carry around boxes of the stuff, plus a printer.

Tip Department

So, while you're doing all this setting up and the like, wouldn't you like a simple little tone generator for testing the setup? Well, if you have a PC type computer, and BASIC, you have an RY generator.

James Kretzschmar, DDS, N4HCJ, sent along this short little program which uses the BASIC SOUND statement to produce tones needed for alignment. The program, which may be entered into GW-BASIC or BASICA is:

```
10 FOR X = 1 TO 200
20 SOUND 2125,.5
30 SOUND 2550,.5
40 NEXT X
50 END
```

This program compiles directly into QuickBASIC as well, for those who want to potchsky (play with) such things. I invite translations of this simple program into other dialects of BASIC.

A few months ago I mentioned the new TRTY program, for PC compatibles, as one new program available for RTTY operation. With the file available on CompuServe and Delphi, I have been watching the downloads mount up, and it appears that many of you have enjoyed the program. I will continue to offer the program, at least through the summer, if you have no other source for it. Send me a 5" or 3.5" blank disk, a self-addressed *stamped* disk mailer, and $2 for handling, and I'll turn it around as soon as I can.

As always, I look forward to your input. Send it to me by mail, at the above address, or on CompuServe (ppn 75036,2501), or Delphi (username MARCWA3AJR). Watch out for the sun this summer (this is Dr. Leavey talking—not the ham), and use sunblock on the kids!

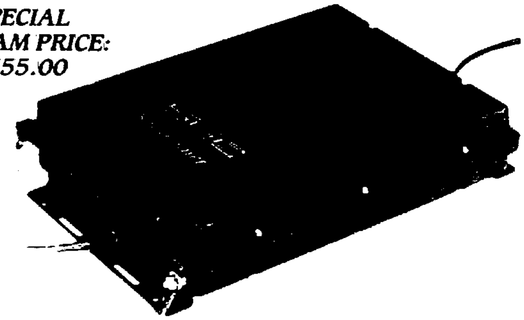
SGC SG-230

SMARTUNER

HF ANTENNA COUPLER—SSB, AM, CW & DATA
FAST—INTELLIGENT—ACCURATE
OPERATES WITH ANY HF TRANSCEIVER

The *Smartuner* high technology coupler intelligently tunes any length antenna (8 to 80 ft) in the HF band. This unit will operate with any HF transceiver within its' specifications. The *Smartuner* switches 64 input and 32 output capacitance combinations plus 256 inductance combinations in a "pi" network resulting in over a half-million different ways to ensure a perfect match for the transceiver. And, *it remembers the frequency and the tuning values* and will re-select these values in less than 10 ms next time you transmit on that frequency.

SPECIAL HAM PRICE: $555.00



Gordon West, WB6NOA, "the Smartuner is the best coupler I've ever tested or used"

- MICROPROCESSOR CONTROLLED
- NON-VOLATILE MEMORY
- WATERPROOF
- B.I.T.E. INDICATOR
- 1.8 TO 30 MHZ RANGE
- 10 TO 150 WATTS INPUT POWER
- 10 MS RETUNING TIME
- 8 TO 80 FT. ANTENNA (ALL TYPES)
